AN

ILLUSTRATED WEEKLY JOURNAL

OF

Horticulture in all its Branches.

Founded by W. Robinson in 1871.

EDITED BY E. H. M. COX.

VOLUME LXXXIX.—1925

LONDON.

Office: 20, TAVISTOCK STREET, COVENT GARDEN, W.C.

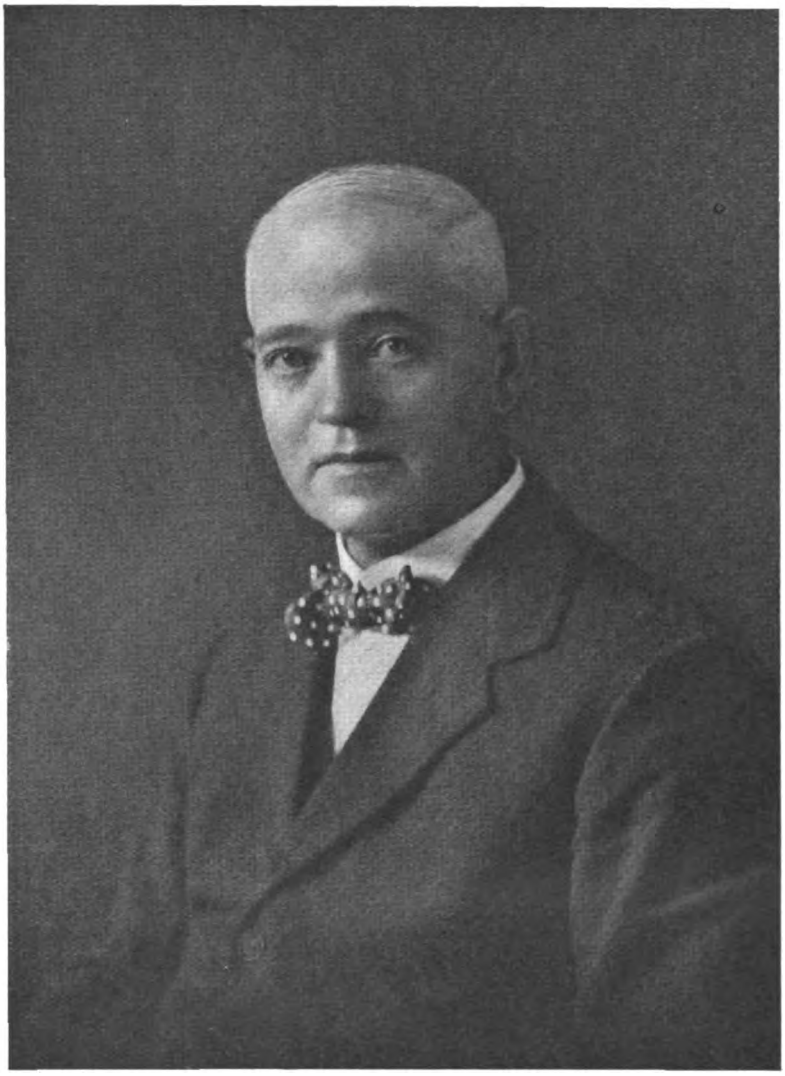
Published by "COUNTRY LIFE," Ltd., 20, Tavistock Street, Covent Garden, W.C., and by GEORGE NEWNES, Ltd., 8-11, Southampton Street, Strand.

Digitized by Google

THIS (THE EIGHTY-NINTH) VOLUME OF "THE GARDEN"

IS DEDICATED, BY PERMISSION, TO

SAMUEL McGREDY, Senr., J.P.



IN the world of roses there is no name more respected than that of Mr. Samuel McGredy, Senior. The fame of his firm as raisers of new roses is world wide. He originally started hybridising as a hobby, and in 1905 exhibited his first gold medal variety, Countess of Gosford. Since then fifty gold medals of the National Rose Society have been awarded to his firm as the result of Mr. McGredy's personal work.

Mr. Samuel McGredy, Senior, is the senior partner of Messrs. S. McGredy and Son, but, unfortunately, during the past few years he has been unable to devote the same amount of time to business as he did in previous years, owing to continual ill-health. Still, he retains the greatest possible interest in all horticultural matters, especially in regard to roses. It is interesting to note that one of his earliest hobbies was fruit growing, and it is safe to say that he has been consulted by every fruit grower in the North of Ireland.

The list of roses that Mr. McGredy has raised is an imposing one. It is impossible to mention them all, but the following are known and admired the world over: Mrs. Herbert Stevens (1910), Old Gold (1912), Isobel, Golden Emblem and Modesty (1915), Flame of Fire and Christine (1916), The Queen Alexandra Rose, his first bi-coloured variety (1917), Mrs. Henry Morse (1919), Mabel Morse (1921), Florence L. Izzard, Mrs. Courteney Page and Vesuvius (1922.).

With such triumphs to his credit it is little wonder that the National Rose Society awarded Mr. McGredy the Dean Hole Medal for 1922, as a recognition of his work in roses.

We have much pleasure in dedicating this volume of THE GARDEN to one who has done so much to beautify and popularise the rose. All rosarians owe Mr. McGredy a great debt of gratitude.

INDEX TO ILLUSTRATIONS

Abutilon, a white, 510; vitifolium, 496
Acacia armata, 443
Acer griseum, 20
Achneria St. Mungo, 672
Agrostis nebulosa, 268
Allamanda Hendersoni, 443
Alpine exhibit, 293; meadow, 245; slopes, 258
Alstrœmeria aurantiaca, 517
Amelanchier canadensis, 305
Anchusa, 418
Androsace lactea, 455; pyrenaica, 455; sarmentosa, 454; tibetica, 545; villosa, 122
Anemone apennina, 612; blanda, 73; Hepatica triloba, 45; japonica crispa, 156; Pulsatilla, 257
Anemones, St. Brigid, 94, 155
Annuals at Ottawa Experimental Farm, 352; Sutton's exhibit of, 296
Ant, 312
Antirrhinum Crimson Glow, 229; Prima Donna, 229
Antirrhinums, 326; in beds, 63
Aquilegia alpina, 228
Aphis, the thistle, 312; winged, 312
Apple, espalier-trained tree, 641; preserving of, 474; Rev. W. Wilks, 555; St. Everard, 555; tree, pruned, 47; tree, unpruned, 46
Apples, cordon, 641
Aralia chinensis, 583
Arbutus andrachne, 608; fruits of, 609
Arenaria balearica, 407
Armeria, 414
Arthrotaxis laxifolia, 613
Aspidium Braunii, 184
Aster Barr's Pink, 656; Phyllis, 637; Thomsoni, 529; Ultramarine, 626
Asters, Chinese, 84
Astilbes, 159
Aubrietia, 284
Auricula, double, 514
Azalea Hollandia, 279
Azaleas at Leonardslee, 283

Babiana plicata, 386
Beans forced in greenhouse, 469
Bedding plants, cuttings of, 507
Begonia Mabel Langdon, 558
Begonias in beds, 327
Bellidiastrum Michelii, 127
Berberis Bealei, 171; Gagnepainii, 585; japonica, 171; Julianæ, 585; nepalensis, 81; verruculosa, 586; Wilsonæ, 537
Betula luminifera, 698; nigra, 697; populifolia, 682; verrucosa, 685
Birch broom, how to make a, 604
Bomarea Matthewsii, 671; Whittonii, 671
Border, herbaceous, 275; herbaceous in July, 359; summer, 348
Borders, 364
Brachyglottis repanda, 399
Brachypodium distachyum, 268
Brodiæa coccinea, 540
Brodiæas, species, 539
Brunsvigia, 643
Buff tip moth caterpillars, 10
Bulbs, potting of, 478
Bursea seedling, 34

Cacti group, 396
Calceolaria pratensis, 379
Campanula pusilla, 406; pyramidalis, 716; Telham Beauty, 717; Warley alba, 475
Campanulas, border, 685; dwarf by pathside, 696
Canterbury bells, 415
Cape sundew, 584
Carnations, perpetual border, 298; Perpetual malmaison, Jessie Allwood, 700
Chelsea, garden exhibits at, 292, 293
Cheiranthus alpinus, 526
Cherries, flowering, 151; on walls, 641
Chionodoxa gigantea, 687
Chionodoxas, 480
Chrysanthemum, in pot, 338; maximum, 685; Mrs. R. F. Felton, 647; Sir Edward Letchworth in pots, 339
Chrysanthemums in greenhouse at Ottawa, 353, 730
Choisya ternata, 120
Cineraria, Webb's new, 297
Cistus ladaniferus immaculatus, 355
Clematis Fargesii, 658; indivisa, 3; montana rubens, 538; paniculata, 4
Clianthus puniceus, 177
Clivia cyrtanthiflora, 527
Collinsia bicolor, 90
Cornus florida, 286; Kousa chinensis, 287; Mas, 115; Nuttallii, 287; racemosa, 596
Corokia Cotoneaster, 554
Cotoneaster humifusa, 226
Cowslips, 269
Crassula falcata, 525
Crinodendron Hookeri, 294
Crinum Powellii, 508
Crinums, 341
Crocus chrysanthus, 429; Fleicheri, 429; Imperati, 428; longiflorus, 16; pulchellus, 598; Sieberi, 17, 428
Currant, black, Blacksmith, 630
Cyclamen, a fine-flowered seedling, 433; Coum, 553; Giant White, 433; Salmon Queen, 432
Cymbidium miranda, 705
Cypress, the swamp, 142
Cypripedium acaule, 361; Elatior var. Shrubbery, 669; Fairrieanum, 668; Maudiæ, 668; pubescens, 360; Reginæ, 360
Cytisus albus, 311; kewensis, 310

Daboecia polifolia, 75, 180
Daffodils in bowl, 483; in wood, 479; ready for market, 203
Dahlia Charm, 200
Dahlias, Mignon, 63; Star, 349
Daphne Blagayana, 435; Cneorum, 636; mezereum, 536; petræa, 227
Davidia involucrata, 389; Vilmoriniana, seedlings of, 679
Decodon verticillatus, 673
Delphinium Coquette, 565; Joybells, 565; Monarch of Wales, 274
Delphiniums, 92; a border of, 457; a well flowered clump, 457
Dendrobium nobile, 683
Deutzia corymbosa, 515; Mezereum, 536; Wilsoni, 515
Dianella tasmanica, 555
Dianthus Allwoodii, 255; Herbertii, 254; microlepis, 216; superbus, 328
Dictamnus albus, 213
Dierama pulcherrima, 657
Dimorphotheca aurantiaca, 90
Diosma uniflora, 319
Dipelta floribunda, 552
Dipteronia sinensis, 448
Dipsacus, 572
Drimys Winteri, 613
Drosera capensis, 584
Dykes, W. R., 702

Erica australis, 616; carnea, 58, 391; mediterranea alba, 555; stricta, 261
Erinus alpinus, 101
Eritrichium nanum, 645, 676
Erodium chamædryoides, 284
Erythroniums, 309
Eschscholtzias, 289
Eucryphia cordifolia, 201; pinnatifolia, 496, 618
Euonymus Bungeanus, 687
Exhibit, Carter's, at Holland Park, 557; Mr. George Prince's, at Bournemouth, 398; Webb's vegetables at Birmingham, 559; Toogood's, at Bournemouth, 397; succulents, 559; Sutton's, at Holland Park, 557
Exochorda grandiflora, 551

Ferns, hardy, 59
Fig in pot, 36
Fothergilla gardeni, 141; major, 141; monticola, 141
Foxgloves, white, in woodland, 441
Frame, 503
Freesia, Apotheosis 499; house, 499; Orange King, 105; Wistaria, 162
Fruit trees, grease banding, 529
Fuchsia Delight, 523; Enchantress, 524; Venus Victrix, 524
Fuchsias in beds, 327

Galanthus Elwesii, 21
Garden, borders and cliffs, 364; designs 592, 593; formal sunk, 365; New Zealand, 569; plan of rose, 578; rockery and Italian pergola, 365; stream, 604; steps, decoration of, 697; summer-house and flower borders, 364; waterside, designed by Cheal's, 291
Gardens, at Glengarriff, 706; at Pruhonice, 231; exhibited at Chelsea, 292, 293; formal, exhibited at Chelsea, 293; exhibited at Olympia, 160; Rideau Hall, 114, 115; Underwood, Bournemouth, 364
Gates, iron, 390
Genista ætnensis, 584; hispanica, 241
Gentiana acaulis, 21; Farreri, 9; pyrenaica, 512; sino-ornata, 9; verna, 122
Gilia californica, 476
Gladiolus, 289; Blériot, 157; Elora, 686; involutus, 387; Mrs. James Kelway, 448; Painted Ladies species, 387; tristis, 387; White Lady, 505
Gloxinia exhibit, 297
Gloxinias, 42, 43
Godetias, 84, 288
Gorse in natural surroundings, 173
Grape vine, Muscat of Alexandria in a cool vinery, 675
Greenhouse boiler, 519; small, 489

Haarlem Show, 236
Hakea laurina, 643
Helenium in the border, 622
Helianthemums, 372
Helichrysum bellidioides, 542, 636
Hellebores, 308
Helleborus niger, 536
Herbaceous plants, exhibit of, 368; propagation of, 660, 661
Hesperis matronalis, 473
Heuchera tiarelloides, 399
Hyacinths in pots, 264
Hydrangea hortensis, 238, 324; Souvenir de Mme. Chereau, 625
Hydrangeas, 325
Hymenocallis macrostephana, 209; speciosa, 527
Hypericum in rock garden, 240

Iberis, 110
Ichneumon fly caterpillars, 10
Iris, abnormal, 491; Alcazar, 403; Aphrodite, 702; dalmatica, 405; exhibit, 295; histrioides, 125; Kæmpferi, 159; Lady Foster, 403; pallida dalmatica, 403; reticulata, 481, 522; Rosenbachiana, 125; sibirica, 404, 703; Spanish, exhibit of, 296; stylosa, 25; tingitana, 51; Wedgewood, 79; walk at Ottawa Experimental Farm, 352
Irises, bearded, by the pathside, 402; bearded, in semi-natural groups, 402; in borders, 340; pallida in border with nepeta, 401

Jasione montana, 636
Jasmine, 595
Jasminium nudiflorum, 537

Kitchen garden, plan of, 631
Kitchingia uniflora, 130
Kniphofia caulescens, 472
Kohl Rabi, 33

Lace-wing fly, 444; cocoon of, 445; eggs of, 445; larva of, 445; pupa of, 445
Lachenalia Boundii, 732; Excelsior seedlings, 129; pendula, 65
Lagurus ovatus, 268
Larkspur, double annual white, 62
Lavender in cottage garden, 351
Lawn mowers, 246; sprinklers, 395
Leucojum vernum, 198, 481
Ligustrum Quihoui, 669; ovalifolium, 670

A CHRISTMAS PRESENT

THE other week I wrote a note on plants as presents. Now some unknown reader has taken me at my word and has sent me a Christmas present. It is a packet of seeds, and I found it in my stocking. They are wrapped in curious soft paper with hieroglyphics written thereon in some unknown foreign tongue. Perhaps the sender is a Russian, for as far as I can make out the writing reads 4291 SAMX SDNOMLA. I thought I knew all the shorthand as used by collectors, but this puzzled me. On the other hand, I am accustomed to slight difficulties in my research among the botanical treasures of the world. As this is a typical case, perhaps some of my readers might be interested in following with me to the conclusion I have arrived at.

First of all, I write down a short non-technical description of the seed. This is it:

"Semis embryo maturissima ovoido elipticale baso blunto apice acuto, in longditudine 2.563183 cm. in latitudine 1.000003 cm. Necessarius est crachulare cum ferocissimis dentibus; integumente tenuiore, rubro-nigra in colore, findetus cum passis rugis. Semis edulis est cum raro vetissimo porto vino."

This simplifies matters considerably if you know Latin; I know what it is not. There is no achenodium, a double achene, as the cremocarp of the umbelliferæ, therefore it is not an umbellifer. There was a short stalk attached to one of the seeds, therefore the plant might have been addicted to geoplagiotropism, which presupposes the fact that it was not a biennial. Under a microscope a section showed there were distinct signs of girder schlerenchyma, which does away with any hope that it might belong to the interesting family of scrophulareaceæ. In case these slight technicalities should bore some of my readers, I shall pass over numerous other interesting experiments as to what it was not and give a hint from which even a novice could name the family. I found that one of the seeds had a slight attack of protocollenchyma. After that it was easy; one after another experiments followed each other in rapid succession in my laboratory. I found that the tissue was kyanophilous, that the quaternary glands were quaquaversal, that zygosis was complete. If any reader has not guessed the family from my clear deductions, I will tell them. It was Rosaceæ.

But here I am stuck; until I have seen the heterocotylous growth I can get no farther. From my examination of the seeds under a microscope I have a very fair idea of the interior economy of the plant. It is only natural that I should, because I have dissected 80 per cent. of the seeds. The other two seeds I have sown in a pot, and here is where the microscopic examination helps: I know exactly the mixture in which to sow them. Two portions of dehydrated fluor spar, a dash of tar and two dashes of hydroxyethiltrimethylamonium hydroxide, and a little dynamite to give it a flavour. The seeds were dusted with arnica before sowing and well watered with weed killer. Now I am sitting back hopefully to wait for results. Meanwhile I have tentatively named the plant Sdnomla Hæmoglobini.

Thus was the first part of my task accomplished. The collector was the next conundrum. 4291 is obviously a collector's number: that is simple, but who was Samx. I cabled to my botanical friends throughout the world. In three days a reply came back from Professor Poppittinovitch of the University of Ekaterinberg: "Know him well, Samx is Samxzcitscz," and then it stopped. There may have been more, but no doubt the cable became overloaded and broke down. The rest was easy. I looked him up in "Who's Who in Botany" and found the following entry:

"Samxzcit, etc. Parentage and breeding doubtful, has followed the pursuit of botany since birth, experimented at an early age in the qualities of granular oats, quickly followed by marvellous perception in judging the nutritious value of wheat, flour, potatoes, etc. At the age of 18 tried the effects of datura, aconite and stramonium on his grandmother. Left suddenly on a botanical expedition to Mongolia where he has been ever since. *Works:* Poison and its Potentialities, Vegetable Alkaloids and their Lethal Doses. *Hobbies:* Surf-riding. *Address:* The Red House, Koko Nor. *Clubs:* The Koko-nor Athletic."

He must be a most talented man, but why should he send me seeds. Some ass at my elbow has just made the suggestion that if read backwards the inscription reads Almonds Xmas 1924. What a coincidence! E. H. M. C.

[The editorial part of the writer should have risen in wrath against the too prodigal use of Latin names in matters horticultural.]

NEW ZEALAND SHRUBS IN ENGLISH GARDENS

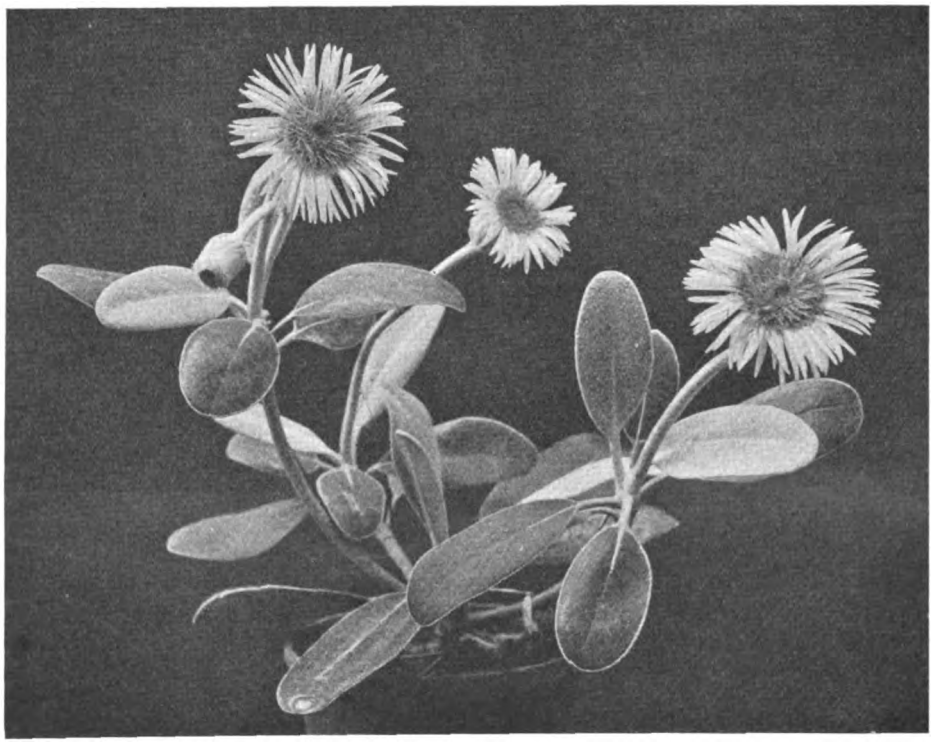
TELLS WHICH OF THESE VARIETIES FROM THE SOUTH ARE MOST SATISFACTORY IN OUR GARDENS.

SO much interest has been shown in New Zealand plants by present-day gardeners that Dr. Cockayne's valuable articles in recent numbers of THE GARDEN will surely add a further stimulus to their cultivation. Unfortunately, a great many of the plants mentioned by Dr. Cockayne are not at present obtainable in this country, but we must look forward with keen interest to their successful introduction.

The dominant feature of the New Zealand flora is the wealth of evergreen shrubs and trees, many of them beautiful in flower as well as in foliage. Many species and varieties of veronica, olearia, senecio and pittosporum are popular plants in British gardens, not only in Devon and Cornwall but all along our southern and western seaboard and in sheltered inland districts.

The following notes on various New Zealand plants (all of which may be obtained from English nurserymen) may prove of some interest to those who appreciate choice plants:

CORDYLINE AUSTRALIS.—The cabbage tree is one of the most distinctive shrubs in cultivation, but unfortunately it is only hardy near the coast. A strikingly sub-tropical effect is easily produced by grouping several cabbage trees with New Zealand flax (Phormium tenax), beschornerias, yuccas and similar plants with noble foliage. The cordyline resists gales wonderfully well and is seldom damaged by snow; when a leaf becomes laden with snow it gently bends down and shoots the snow off. They grow very rapidly in good soil and begin to flower when six or seven years old. The small white flowers are borne on a very large branching inflorescence and are deliciously fragrant. Cordylines flower freely in a spring succeeding a hot summer; after a dull, cold season there will be few flowers. Cordyline indivisa is a dwarfer species with much wider foliage of great beauty, but comparatively rarely seen in our gardens. C. Banksii is a smaller species, with long narrow leaves and quite as hardy as C. australis.



OLEARIA INSIGNIS, NOTABLE FOR ITS LARGE THICK LEAVES.

CLEMATIS INDIVISA.—This well known favourite of cool greenhouses is a truly glorious climber in districts where little frost is experienced and where it can be allowed to ramble through a large tree. Its great clusters of starry white flowers are borne in March and April and show up well against the thick evergreen foliage. It is easily propagated by cuttings inserted in a sand frame in June or July, or layers may be taken in pots.

PITTOSPORUM TENUIFOLIUM. — A magificent hedge plant for mild maritime districts. The rich green undulate leaves and black branches are very striking, and it bears clipping well. It soon forms a beautiful pyramidal specimen if allowed to grow naturally. There is a handsome silver-variegated form and several closely allied species. The flowers of most New Zealand pittosporums are small and purplish black; they would easily escape notice were it not for their strong honey scent, which is exhaled only at dusk to attract night-flying insects. Pittosporums come readily from seed and should be planted in their permanent position when still small.

RUBUS AUSTRALIS.—The " Bush Lawyer " is more strange than beautiful, but worth a place in the gardens of " the curious." In the leafless form the stems are armed with innumerable sharp prickles like tiny sharks' teeth. One can readily understand that it is easier to fall into its clutches than to get out of them—hence its popular name, bestowed on it by the colonists.

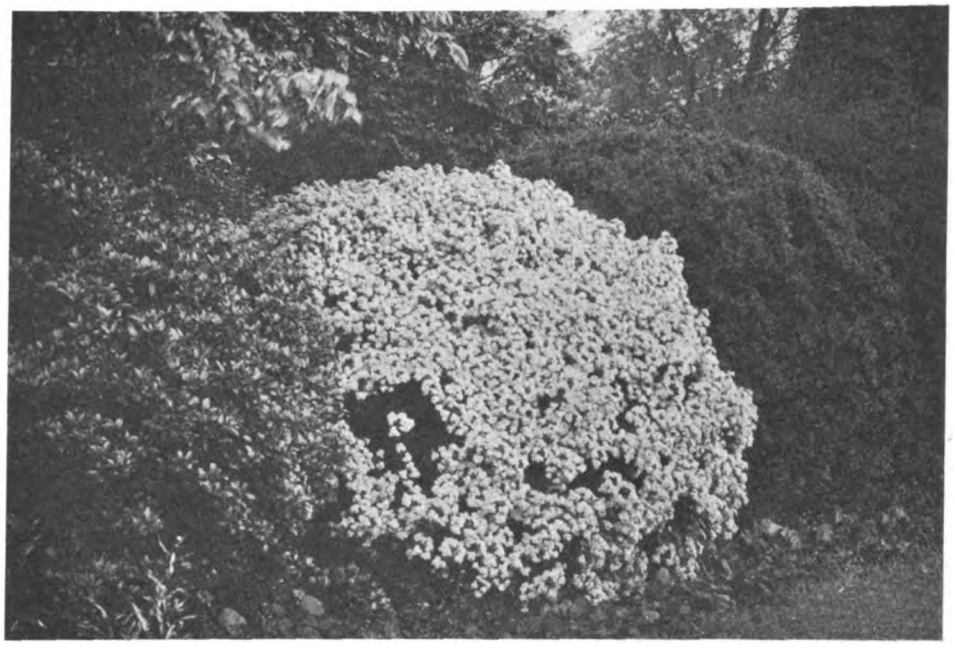
CARMICHAELIA and NOTOSPARTIUM are closely allied genera, usually known in this country as " pink brooms." Both are interesting but not showy small shrubs, though the individual flowers are very pretty when closely examined. Notospartium Carmichaeliæ is the better of the two, but Carmichaelia australis is rather more hardy. There is a rare dwarf species of Carmichaelia (C. Enysii) which is well suited to a nook in the rock garden.

CLIANTHUS PUNICEUS, " lobster-claw " or " red Kowhai," is one of the most gorgeous flowering shrubs in cultivation. It is said to be extremely rare in the wild state now, but luckily is very popular in gardens in New Zealand as well as in this country. The large pendent clusters of bright scarlet flowers nestling among the pinnate shining green foliage attract the attention of the least observant passer-by. A high south wall is the ideal position for a clianthus, but where this is not available it will succeed on an east or west wall. It is evidently a short-lived plant, and is liable to collapse suddenly without any obvious cause: luckily it grows very rapidly, and a healthy young plant will soon fill up the space left vacant. Seeds germinate easily but must be protected from slugs and mice, both pests being much addicted to the tender young shoots. Seedlings should be pot-grown until put in their permanent position, as they transplant badly. The white variety of the lobster claw is less striking than the scarlet type, but is none the less a lovely flower and well worth a choice position. During hard frost a light protection may save the clianthus from severe injury, but it must not remain covered up for long. Nearly allied to clianthus are the equally interesting yellow-flowered forms of Sophora tetraptera (often listed in catalogues as Edwardsia). This is the true " Kowhai " of the Maoris and has been chosen as the national flower of New Zealand. Sophora is somewhat hardier than clianthus and may be grown in the open in sheltered spots. The small leaflets vary greatly in number according to the age of the plant; in a young plant a leaf will be composed of about six pairs of leaflets, but the leaves of an old tree will consist of any number of leaflets up to forty pairs. S. microphylla is more frequently grown than S. grandiflora, but they are both splendid flowering shrubs for mild districts. Although almost evergreen, they frequently shed their foliage in early spring just before the flower-buds open. Kowhai timber is highly esteemed in New Zealand on account of its great durability.

Digitized by Google

The handsome white-flowered LINUM MONOGYNUM is well known in English gardens and is often seen flourishing in sunny corners of the rock garden. It is a true flax and must, of course, not be confused with the totally different New Zealand flax (Phormium tenax), which belongs to the lily family.

POMADERRIS ELLIPTICA is a little known but charming small shrub for mild districts. A correspondent to THE GARDEN kindly sent me seeds from New Zealand a few years ago, from which I raised plants now about 5ft. high, which flowered freely last spring and are again well laden with buds. It is a curious habit of pomaderris to carry its flower buds all through the winter looking as though they would open any day. The flowers are yellow, individually small, but borne in such profusion that the plant appears smothered with blossom. There is another larger species sometimes met with, called P. apetala, but it has little beauty of flower and seems to me very inferior to P. elliptica.



THE MOST POPULAR AND BEST OF THE DAISY BUSHES, OLEARIA HAASTII.

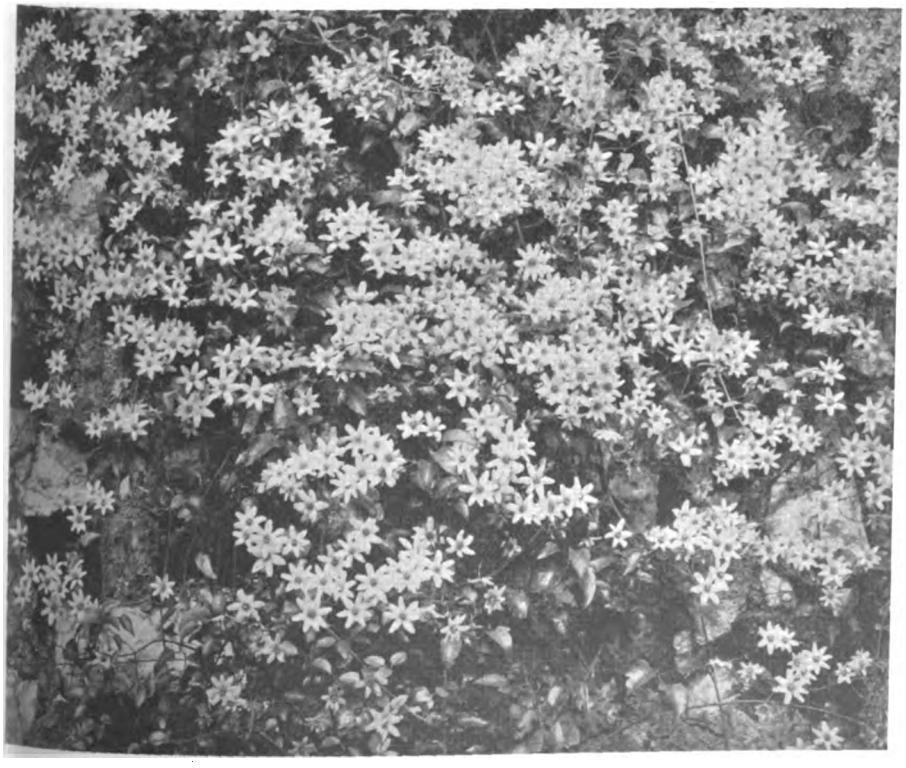
ELÆOCARPUS.—The two species of this shrub found in New Zealand, can only be grown in the most favoured British gardens, but are well worth a place in a cold house elsewhere for the beauty of their sprays of lily of the valley-like flowers and exquisite blue berries. I have tried seeds sent from New Zealand several times without success, but I believe cuttings can be struck in gentle heat.

HOHERIA POPULNEA (the lace-bark) is much hardier, and as it flowers in the open from August up to November its beautiful snow white flowers are particularly valuable. H. p. lanceolata is a variety (or perhaps a distinct species) with narrower leaves and flowering earlier in the season. It is equally beautiful.

PLAGIANTHUS BETULINUS is seldom grown, although it quickly develops into a very graceful and handsome tree, especially when covered with its small greenish blossoms in spring. Unless plants of both sexes are grown no seed will be produced, but if a male and female tree are near one another a crop of seedlings will probably appear beneath the female tree. Like most New Zealand shrubs, they should be finally transplanted when small. P. betulinus must not be confused with the Australian P. pulchellus, which is a very inferior species.

GAYA LYALLII is a well known and deservedly popular shrub; there are several distinct forms in cultivation and seedlings vary to a considerable extent. It is frequently grown against a wall, but in southern England, at any rate, it is quite hardy enough to be grown in the open.

HYMENANTHERA CRASSIFOLIA is another fairly familiar shrub which is occasionally grown as a low hedge. Its attraction, however, lies in the curious piebald berries which it carries in such profusion every autumn on the lower side of its branches. One wonders what object the plant has in view for concealing its berries so completely from the sight of passing birds.



ONE OF THE MOST BEAUTIFUL CLEMATISES, C. INDIVISA.

MYRTLES. — Some of the most beautiful of all New Zealand flowering shrubs belong to the family Myrtaceæ. The myrtles themselves are represented only by three or four species, of which Myrtus bullata is the most striking. The leaves are large (1in. or 2ins. long), reddish brown and curiously swollen between the veins. The flowers are much like the common myrtle, but the berries are red instead of black. It is not a very easy plant to establish and is certainly more tender than the much smaller Myrtus obcordata, which seems quite easy in a sheltered border.

LEPTOSPERMUMS (manukas or tea-trees of the colonist) take the place of the British gorse and broom on poor sandy soils. L. scoparium is now largely grown in this country, but does not seem to succeed far inland. In gardens where it thrives it makes rapid growth and is smothered with lovely white blossoms every spring. Hundreds of seedlings appear near the old plants and have to be weeded out ruthlessly or they would monopolise the whole garden. Very beautiful varieties of L. scoparium have been introduced of recent years, notably L. s. Nichollii with crimson flowers and Boscawenii

Digitized by Google

and Chapmannii with large pink flowers, but these last seem more tender than the type.

METROSIDEROS (bottle-brush plants) are among the very choicest of all New Zealand trees, but alas! they can only be attempted outdoors in the Scilly Islands or the warmest Cornish gardens. Great trees of M. robusta and M. tomentosa ablaze with scarlet blossoms must be a marvellous sight, but M. lucida is the only species likely to succeed at all in most gardens. Although it is said to attain a height of 60ft. in its native haunts it does not get much opportunity here to show what it can do as a hard frost cuts back the young shoots severely.

FUCHSIAS.—None of the three fuchsias peculiar to New Zealand compares in beauty of flower with the South American species, but the little F. procumbens has long been a favourite for rock gardens and greenhouses, owing to its neat trailing habit and large purplish-red fruits. The flowers are not showy, but carry most beautiful blue pollen, a feature shared by its compatriot, the big Fuchsia excorticata. This attains the dimensions of a tree and is one of the few deciduous New Zealand trees. It seems fairly hardy in this country, but does not flower freely until it attains some size.

COROKIA COTONEASTER is an attractive small shrub with interlacing black branches, starred with small yellow flowers in early summer, followed by small red fruits. C. buddleoides is a larger shrub, less hardy and consequently seldom grown except in very mild districts. Griselinia is fairly often met with in seaside gardens where it stands wind and salt-laden spray well, but it cannot be called very handsome or distinct-looking as usually seen. In New Zealand the griselinias are valuable timber trees and are doubtless imposing subjects.

The HEATH family (ericaceæ) are not strongly represented in the Dominion, nor are those which do occur particularly noteworthy. Several species of gaultheria are found in both islands and are now becoming established in British gardens. A very handsome evergreen shrub which is sometimes grown here is Myoporum lætum, whose bright green shining leaves are full of translucent oil glands which give them a very striking appearance. The flowers are white with a lilac tinge, borne in clusters of from three to six. Solanum aviculare is a very quick-growing shrub which attains the height of 8ft. in a single season, but as it cannot resist more than a few degrees of frost it generally gets severely cut (if not actually killed) in winter. The violet flowers are very large for a solanum, and are followed by oval fruits the size of a pigeon's egg, which are said to be edible. Self-sown seedlings appear all over the garden where a plant has fruited, so that it is easy to replace when the old ones have perished.

The New Zealand VERONICAS are so numerous and variable a genus that it requires a specialist to determine them correctly. Many fine hybrids have been raised between various large-flowered species in beautiful shades of blue, purple and crimson.

The COPROSMAS are well represented in the New Zealand flora, but are seldom seen in this country. Some of them bear beautiful blue berries and appear to be quite hardy so that they would be desirable additions to our gardens.

Most of the OLEARIAS in cultivation in Britain are natives of New Zealand (O. Gunniana, however, is a Tasmanian). The praises of O. macrodonta and O. nitida have often been sung by West Country gardeners, and they are certainly the two most useful species. The popular O. Haastii is, of course, extremely hardy, but cannot vie with the others as regards beauty. O. insignis is, indeed, remarkable for the size of its broad thick leaves covered with a greyish bloom above and white beneath. O. semi-dentata with mauve florets is very charming, but, like many of the Chatham Island plants, seems to be more difficult to establish in many gardens than other olearias.

The shrubby SENECIOS are useful grey-foliaged plants of which S. Greyii is the commonest in cultivation. A much more striking representative of the compositæ is Brachyglottis repanda, which makes a very handsome shrub in the open in the West of England. The leaves are large and soft, dull green above, white beneath, as is the rule with so many New Zealand shrubs. It produces large terminal panicles of whitish flowers, especially after a hot season when the wood has been well ripened.

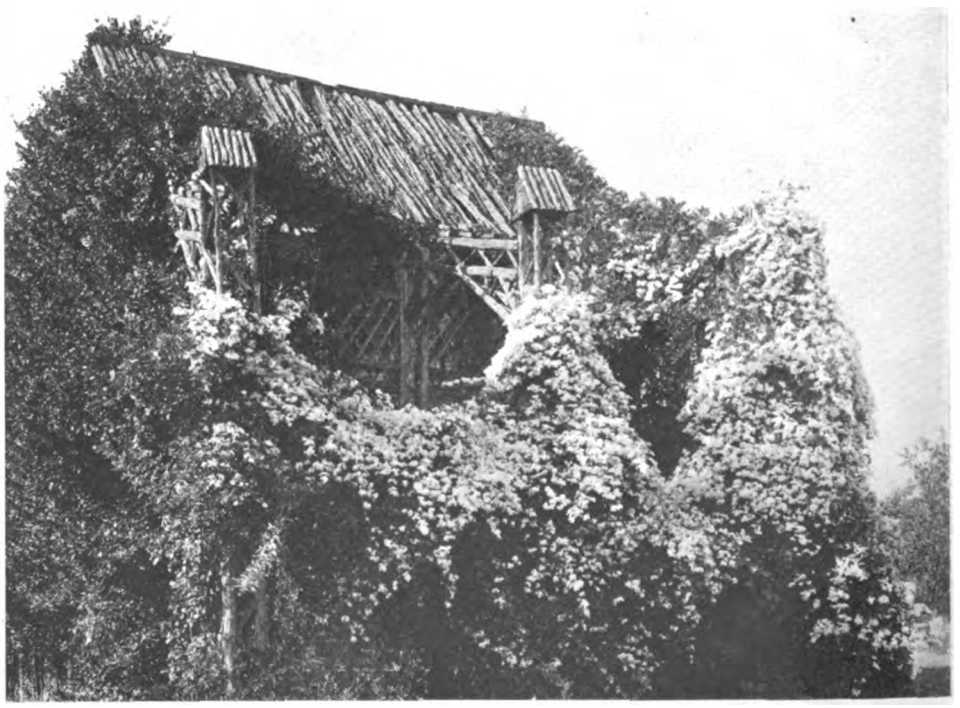
N. G. HADDEN.

A FINE CLEMATIS

BY E. H. WILSON.

ONE of the most beautiful plants that blossom in the autumn is the climbing Clematis paniculata, much too rarely seen in British gardens. Possibly England does not enjoy enough sunshine for this plant to give of its best, yet it is so beautiful that it ought to be given further trials and especially in the sunnier parts of the British Isles. On this side of the Atlantic it is one of the most popular climbing plants, never failing in the autumn season to put forth its flowers in countless thousands. A vigorous plant it will grow, full 30ft. or more, forming a thick tangle. Dark, lustrous green through the summer, and a garland of pure white through September, this clematis is to be seen in nearly every garden. In many places it has escaped and become naturalised. The flowers are pure white, delightfully fragrant, each about an inch across, and produced in paniculate clusters from the axils of the current season's growth. The three to five partite leaves are a dark lustrous green and from early summer to late autumn this plant is a thing of exquisite loveliness. Festooning pillars or porches or rocks, it is one of the most beautiful of hardy climbing plants.

A native of the Orient, C. paniculata was introduced into cultivation from Japan by the Russian botanist, Maximowicz, about 1864. The Arnold Arboretum obtained seeds of it from the Botanic Garden, Petrograd, in 1877, and the plants raised from these seeds were the parent stock of the many millions now grown in America.



CLEMATIS PANICULATA ON AN OLD SUMMER HOUSE IN MASSACHUSETTS.

SAXIFRAGES NEW OR NOTEWORTHY

THIS IS ONE OF THE LARGEST OF ALL FAMILIES IN THE GARDEN, SO THESE NOTES BY A PRACTICAL GROWER SHOULD BE OF GREAT ASSISTANCE TO READERS OF "THE GARDEN."

MANY new varieties have been added to the various sections of this popular and important family of alpine plants. While some, though good, are not a great improvement on older and consequently better known kinds, others have proved to be of exceptional merit in more ways than one, and are especially fine when grown as specimens in an alpine house or cold frame, the former, of course, for preference. Such a convenience is not absolutely necessary, but with it perfection can really be attained and enjoyed to the full, particularly so with the Engleria and Kabschia sections, as inclement weather conditions so often prevail at their flowering season; birds and slugs also feed on the blossoms and mar their beauty to a considerable degree. Under cover these annoyances are overcome and the full beauty of both flower and foliage is brought out perfectly. The latter alone being a source of pleasure, perhaps more so at this time of the year when it is at its best. By these remarks I do not wish to convey an impression detrimental to the uses of such an accommodating family of plants in the rock garden.

SAXIFRAGA COTYLEDON PLATYPHYLLA is undoubtedly the giant of the encrusted group, having handsome rosettes almost 1ft. across when well grown. The leaves are very broad and finely toothed, while the immense arching stems, clothed with sprays of snowy white flowers, attain under good cultivation 4ft. to 5ft. in length. Flowering in June, they remain in perfect condition for weeks on end.

S. DR. RAMSEY.—Those who know this superb variety will, I think, agree that it is one of the best if not the finest saxifrages of its kind ever introduced. It is beautiful both in flower and foliage. The individual flowers are large and well formed, the colour being clear white with rich red spots. The spikes are about 1ft. in height, evenly balanced, without the rather dense heads so characteristic in some varieties of this section. Its whole habit leaves little to be desired, almost every rosette terminates in a beautiful flower-spike in June.

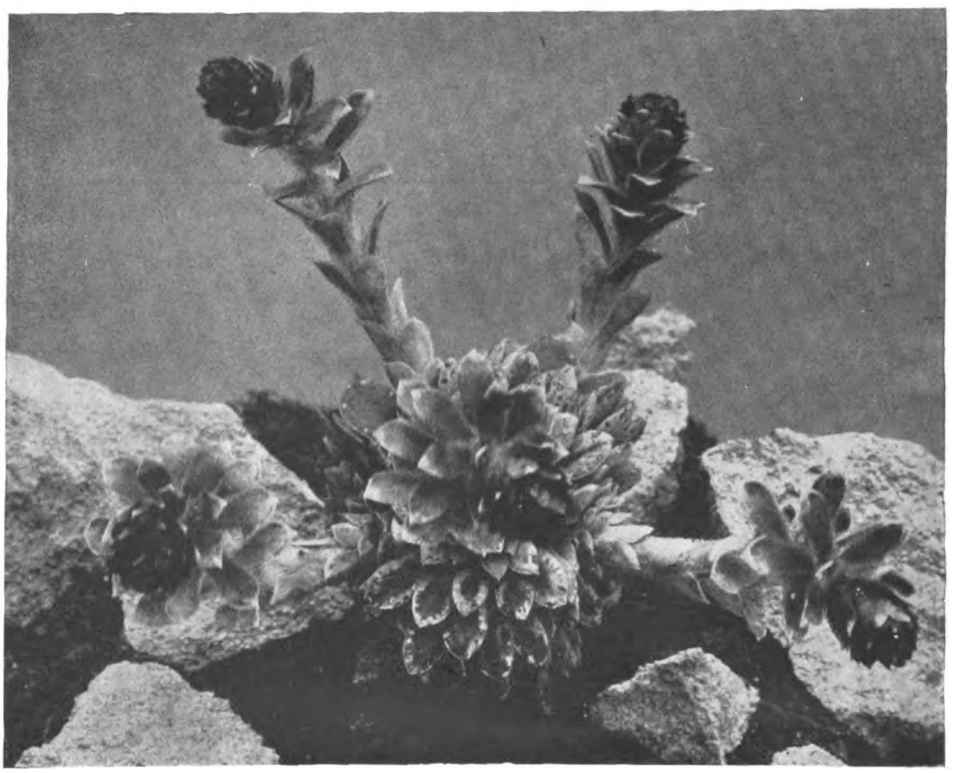
S. LONGIFOLIA.—This handsome species is too well known to dwell upon, but impossible to pass over. Suffice it to say that its symmetrical spikes of white flowers are exceedingly attractive, that is when it does condescend to throw up its spike, which it assuredly will in spite of one's efforts to prevent its doing so. Personally, I regret the appearance of such, for it means the loss of a specimen which with care will attain almost huge dimensions as far as this class of plant is concerned. In leafage no other member of the group is comparable. Fortunately, young plants of it are cheap and easy to procure.

S. FLORULENTA.—Owing to the recognised difficulty in the cultivation of this pink-flowering species from the Maritime Alps it is seldom seen. Naturally, no grower cares to admit defeat, and such a plant as this usually adds to his incentive to succeed. It is of importance to place it in a vertical position and at all times handle with respect. Bearing these two points in mind anyone hardened to these difficult creatures might reasonably hope to be successful.

The Kabschias have, I think, grown the richest of any section, and as these are of easy culture perhaps it is as well that it should be so.

S. HYBRIDA H. MARSHALL (Burseriana floribunda × lilacina) is the first of the new ones to flower here in the North, that is, about the middle of March, about the time that the well known Irvingi is past its best. The flowers are pale pink, of good substance, borne singly on erect 3in. stems above a dense grey-green foliage. Another desirable form from the same cross, called S. hybrida Gem, is very similar excepting that the flowers are much more reflexed and fully a fortnight later. The varieties Amitie (lilacina × dalmatica) and Etheline (Tombeana × Burseriana crenulata) are worthy of mention. With the introduction of these new hybrids by Messrs. Maurice Prichard and Sons of Christchurch the particular shade of pale pink first brought out in S. Irvingi has been considerably lengthened, a valuable asset where the decoration of an alpine house has to be kept in view.

S. ARCO-VALLEYI was sent us by Messrs. Tucker and Sons of Oxford, and is included by them among the Engleria group and described as a red hybrid, but the plant here is totally different, appearing nearer to the Kabschias with flowers of rich lilac, large, round and well formed on 3in. stems, the petals overlapping as in S. Faldonside and remain in perfect condition throughout April and well on into May, the colour improving with age. Undoubtedly it must be in the first dozen of a large collection here at Dupplin Castle.



ONE OF THE MOST STRIKING OF SAXIFRAGES, S. GRISEBACHII.

S. MYRA.—I can but endorse the general praise accorded to this remarkable cherry red hybrid, and I only hope that the form coccineum will turn out to be as stated, "an even richer form."

S. RIVERSLEA (Frederici-Augusti × lilacina) forms silvery hillocks of rosette-like growth and has flowers of a purplish hue early in February. A somewhat similar plant but with much richer flowers received an award of merit from the Royal Horticultural Society in March, 1923, and is called S. Valeria Keevil.

S. GRISEBACHII (WISLEY VARIETY) is to my mind the most handsome of the Engleria both in its foliage of hard silvery rosettes which on specimen plants measure 2½ins. across, especially beautiful in appearance. The flower-spikes, which appear in spring, are very striking and curious, clothed as they are with purplish crimson and green-tipped bracts.

J. T. HARRIS.

SOME NEW ROSES OF 1923

BY HERBERT C. WETTERN.

A CRITICAL LIST OF ROSES OF 1923 WHICH HAVE BEEN TESTED IN THE AUTHOR'S GARDEN.

IT can well be argued that it is hardly a fair test of a new rose to try one plant of each variety, but at any rate some experience is gained thereby, even if the observation of a second year is essential to confirm one's first impressions.

Admittedly better, or more decisive tests can be made, for example, in the Royal Horticultural Society's Test Garden at Wisley, where half a dozen plants of each new variety are tried, and even better experience can be gained by the combination of the two efforts.

Variations in soils, in climate, in situation—all these factors admittedly can affect the results, and emphasise above all the advisability of making such tests in different places and under varied conditions. As an example, we find that Messrs. Alex. Dickson's roses from Newtownards make little success here as compared with the roses from their Marks Tey Nurseries. The latter, coming from a heavy soil on to our light sandy loam soil, always do well. The reason is not easy to explain, but it is a fact, nevertheless.

Our inglorious summer—if such it can be called—has been far from ideal for testing plants of any description—above all roses. The sun certainly shone in June, but thereafter it has almost been continuous wet throughout the country, a condition calculated of itself to damp the enthusiasm of the most ardent rosarian, while affording the poorest opportunity for the plant to put forth its best efforts.

The results, therefore, set out hereafter really form a record of observations made under these difficult conditions, and must be accepted as subject to future experience, producing evidence which will confirm, or even in some cases directly contradict, the tentative conclusions so far reached.

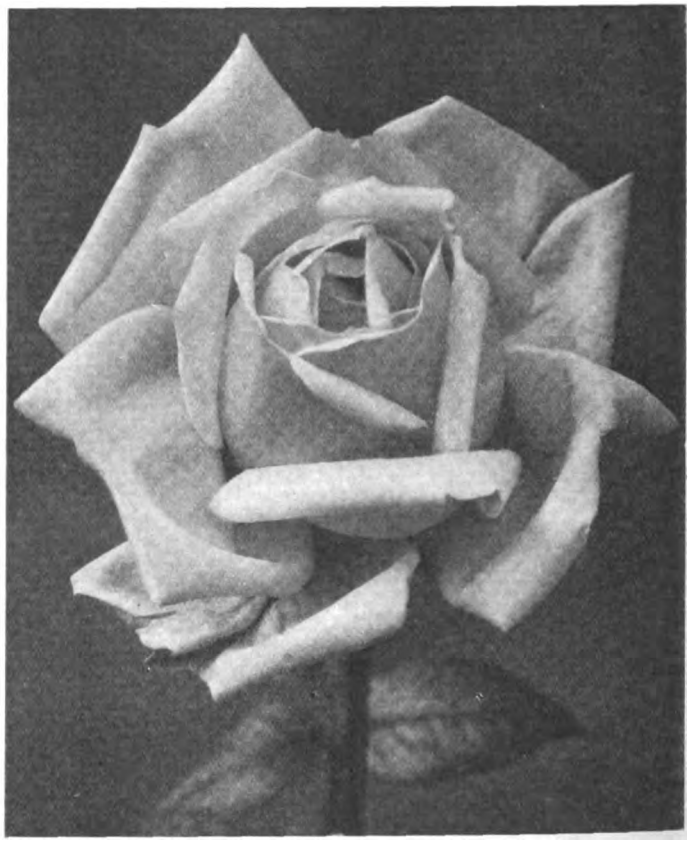
Barbara, H.T. (W. E. Chaplin).—Catalogued also as a pernetiana. Strong grower, free bloomer. Bright red blooms with yellow base, and yellow reverse of petals. Semi-single, height 18ins., foliage good. A very bright bedding rose and a striking novelty.

Betty Hulton, H.T. (Alex. Dickson and Sons).—Clara Curtis type. Nice habit with vigorous growth. Large pointed bud, clean yellow blooms, which open freely in all weathers. Height 15ins., dark foliage. An excellent new variety, suitable for massing in beds, and most blooms good enough for exhibition. A very promising rose.

Captain F. S. Harvey Cant, H.T. (Frank Cant and Co.).—Good grower. Blooms pale pink, hardly salmon as described, with yellow base. The blooms are large and of great substance, carried on erect stems. Height 18ins., large foliage. Should be an excellent exhibition rose, though perhaps rather heavy for a bedder. Gold medal N.R.S.

Captain Ronald Clerk, H.T.—Also catalogued as a pernetiana. Splendid grower. Although the growth sprawls, the blooms, being light, keep well off the ground. Wonderful vermilion red blooms with orange base. Height 24ins., good foliage, sweet scented, fine autumn blooms. An attractive garden and decorative rose.

BETTY HULTON, WITH CLEAR YELLOW FLOWERS.



A NEW CORAL PINK H.T., MRS. TRESHAM GILBEY.

Courage, H.T. (S. McGredy and Son).—Good growth, not too rank. Large blooms, dark red, described as similar to old H.P. Duke of Wellington. A good description, too, for colour and growth, but has a freedom of bloom as with the modern hybrid teas. Blooms are a good shape, large and full. Very fragrant, height 18ins., foliage good, large leaves, good autumn blooms. A very promising bedding rose.

Earl Beatty, H.T. (W. E. Chaplin).—Strong growth, but "stubby." Blooms are deep crimson, very fragrant, but discolour somewhat when old, and do not keep their shape well. Height 15ins., foliage, large leaves.

Evelyn Murland, H.T. (Alex. Dickson and Sons).—Growth none too strong and rather sprawly. Deep pink blooms suffused orange. Height 24ins., foliage good, small leaves, good autumn bloomer. Warrants another year's trial to try to get better growths.

Florence L. Izzard, H.T. (S. McGredy and Son).—Good growth, though somewhat thin. Free bloomer, very bright yellow blooms and pretty buds. Height 24ins., foliage good, good autumn blooms. It should make a magnificent bedding rose. Mr. McGredy set too high a standard with Golden Emblem and Mabel Morse and this is hardly equal to either for size or shape. Gold medal N.R.S.

Digitized by Google

Hawlmark Scarlet, H.T. (Alex. Dickson and Sons).—Growth not very strong, or is it that Newtownards plants do not do so well on our soil as those from Marks Tey? Bright scarlet blooms, sweetly scented. Continuous bloomer, height 24ins., foliage good. Gold medal N.R.S.

Jacqueline, Hybrid Briar (W. E. Chaplin).—Also described as a pernetiana. Very strong bush, too big for bedding, more a shrubbery rose. Semi-double blooms, reddish copper, with yellow base. Splendid autumn blooms, big trusses. Free flowering, height 42ins., foliage good. Award of merit R.H.S.

Lady Dixon Hartland, H.T. (B. R. Cant and Sons).—Strong growth. Large blooms, deep shell pink colour, suffused orange, which last well when cut. Height 21ins., foliage good. A most promising bedding rose, giving splendid autumn blooms.

Lady Roundway, Pernetiana (B. R. Cant and Sons).—Strong, but stubby growth. Blooms not large. Clear copper chrome colour. Height, 15ins., good bronze foliage, continuous and free flowering variety, suitable for massing. Gold medal N.R.S.

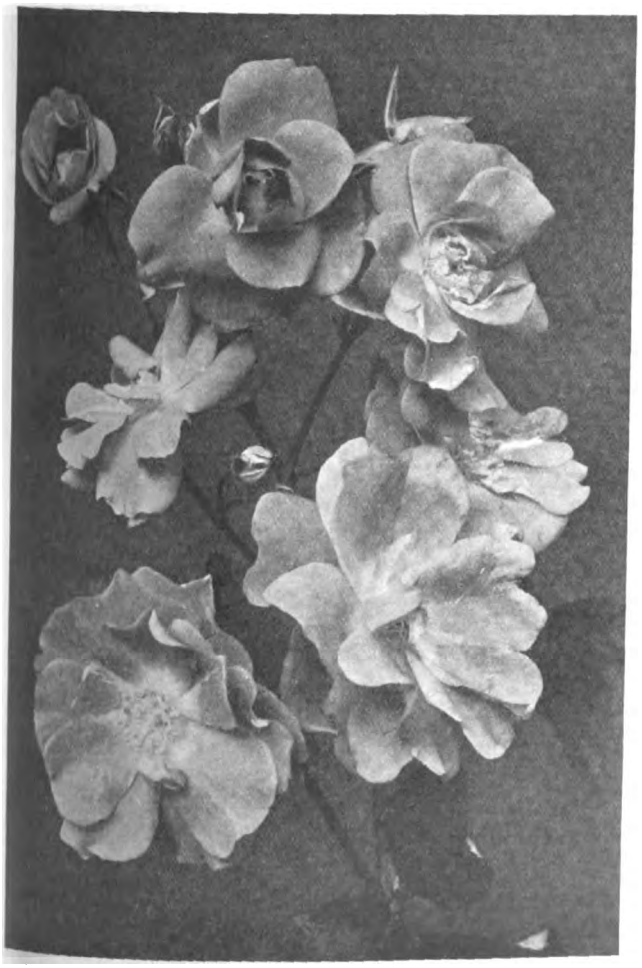
Lord Allenby, H.T. (Alex. Dickson and Sons).—Growth not strong. Scarlet crimson blooms, rather flat, though with plenty of substance. Height 12ins., foliage good. Must try it again in hopes of better growth.

Maud Cuming, H.T. (? Pernetiana) (Alex. Dickson and Sons).—Unfortunately this also has not grown strongly here. Blooms are pinky peach colour, so far not of much size. Height 15ins., foliage good, good autumn blooms. Recommended as suitable for exhibition, decorative and garden purposes, which we shall be better able to judge after another year's trial.

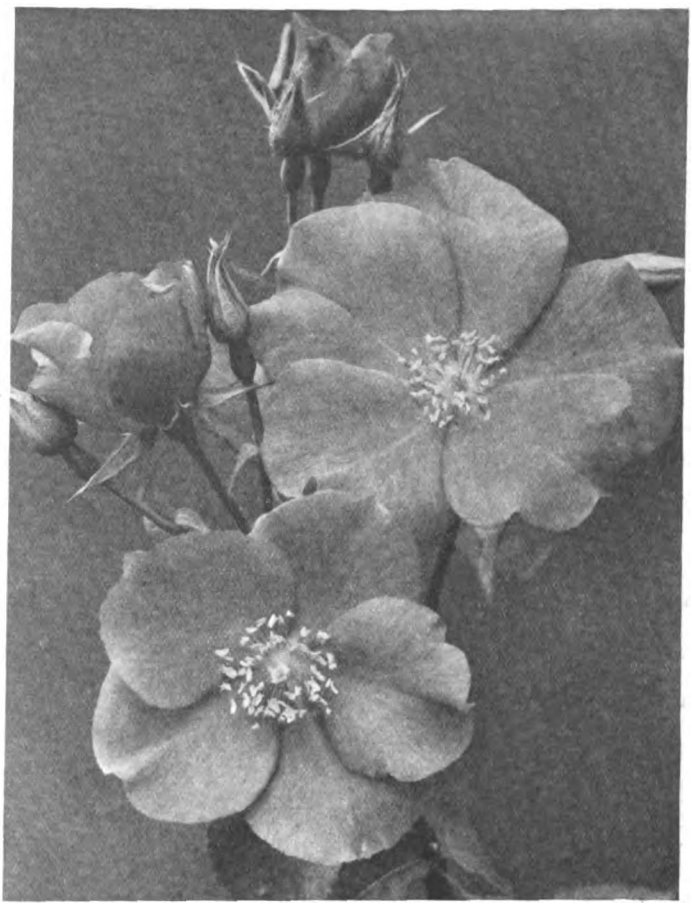
Mrs. Courtney Page, H.T. (S. McGredy and Son).—Strong growth and good shapely plants. Excellent buds. Bright blooms, cerise to carmine shade. All blooms come a good shape. Sweetly scented, height 21ins., foliage fair. Gold medal N.R.S. Claimed to be one of the most superb roses ever raised. *Nous verrons.*

Mrs. Tresham Gilbey, H.T. (W. E. Chaplin).—Very good growth, strong and erect. Long pointed buds resembling Admiration in colour. Blooms coral rose pink. Height 24ins., foliage good, good autumn blooms. Gold medal N.R.S. Although recommended for exhibition, it is hardly heavy enough.

Nur Mahal, Hybrid Musk (J. H. Pemberton).—Bushy growth. Wonderful mass of very profuse bloom. Pink blooms, which lose colour somewhat on maturity. Height 24ins., foliage small but good, splendid autumn blooms.



A VALUABLE AND PROFUSE HYBRID MUSK, NUR MAHAL.



VESUVIUS, A FRAGRANT AND VIGOROUS AUTUMN CROPPER.

Orange King, Dwarf Poly. (Wm. Cutbush and Son).—Growth good. A novel break of colour, orange, but not the colour of a rose. Inclined to break away from its true colour. Height 15ins., foliage good, good autumn blooms.

Rosabel Walker, H.T. (Frank Cant and Co.).—Shapely growth, making excellent bush, and would probably succeed well pegged down. Bright crimson blooms, fragrant, though flat, height 24ins., good autumn blooms. Awards of merit N.R.S. and R.H.S.

Salmon Queen, Dwarf Poly. (Wm. Cutbush and Son).—Growth like Orange King. Blooms slightly pinky-orange. Height 12ins., foliage good.

Scarlet Bedder, H.T. (Jersey Nurseries, Limited).—Origin, General McArthur × Hugh Dickson. Strong bushy grower, similar to General McArthur in shape. Scarlet blooms, but they blue off. Height 24ins., foliage good.

Sea Spray, Hybrid Multiflora (J. H. Pemberton).—Summer-flowering rambler. Strong growth. Poor blooms, pink and white. Height 30ins., foliage excellent, no autumn blooms.

Vesuvius, H.T. (S. McGredy and Son).—Shapely plants. First crop blooms none too free, but makes up for it with autumn crop. Single, scarlet crimson, good colour, and keeps its colour too. Very fragrant. Resembles Princess Mary, but darker. Height 24ins., foliage good. Certificate of merit N.R.S.

Foreign roses tried are as follows:

Asun Galindez de Chapa, H.T. (Ketten Frères).—Origin: Paul Lede × Jacques Vincent. Not a strong grower. Blooms rather small, but of a clean and pinky orange colour. Good autumn bloomer, but must be watched for mildew, height 18ins.

Amelie de Bethune, Pernetiana (J. Pernet-Ducher).—Good and neat growth, throwing up long shoots with excellent trusses of bloom. Blooms are large, bright coral pink colour and cupped in shape. Height 30ins., with bronze green foliage. Excellent autumn blooms, and should prove a good bedding variety.

Etienne Rebeillard, Pernetiana (J. Pernet-Ducher).—Hardly a strong grower. Blooms come semi-single of an ordinary pink colour. Height about 18ins., and the only redeeming feature about this variety is its excellent light green foliage.

Digitized by Google

Insulinde, H.T. (G. A. van Rossem).—Origin: J. M. Jolles × Melody. Growth is good, but apt to sprawl somewhat. Blooms are not large and rather like Golden Ophelia, though a better shape. Bronze yellow colour, height 15ins., foliage dark and good, autumn blooms disappointing, as colour is lost and in a wet season are apt to fade almost to white.

Jan Steen, H.T. (Jan Spek).—Origin: Dora van Tets × Grüss an Dresden. Dumpy growth and weak. First blooms rather shapeless, resembling Dora van Tets. Autumn blooms were better. Height 12ins. Watch it for black spot, to which it seems liable.

J. Bienfait, H.T. (G. A. van Rossem).—Origin: Mme. Léon Pain × Red Letter Day. Good bushy growth. Blooms are semi-double, dark red colour. Height about 21ins., foliage dark green, but seems liable to mildew.

Yellow Bedder, Pernetiana? (G. A. van Rossem).—Origin: J. M. Jolles × Mme. E. Herriot. Very strong grower, making a big bush. Bloom proved rather disappointing, yellowish white, in large trusses. A fine weather variety, under which condition it blooms profusely, and the colour is a cleaner yellow. Height 30ins., foliage small, grass green colour.

Summarising, it is at least evident that there are some very promising new varieties, which have already demonstrated that they are real improvements on many which already exist, but, owing to the inconclusive character of the test, due to the really poor weather conditions, a clear judgment must be reserved until the results of another year's fair trial are known.

PROPAGATION OF NOMOCHARIS BY SEED

BY L. B. STEWART.

THE raising of this wonderful Liliaceous plant is one that has been of great interest in the Royal Botanic Garden, Edinburgh, and more so after a conversation with Mr. E. H. M. Cox, as he told me that the bulbs of this plant were found 2ft. or more deep down in the ground in its native habitat—so deep that it was a problem to know how the plant ever got down.

It is a well known fact among horticulturists that many bulbs have the power to raise or lower themselves according to their own requirements. But the movement in most bulbs is a slow process and it may take the bulbs years to adjust themselves.

In the year 1922 seed was sent to this country, and seed was presented to this establishment through the kindness of Mr. R. Cory. The seed was treated in two different ways. Two 4in. pots of each kind were sown and placed in a warm pit, the temperature of which was 58° night and 65°–70° day. After germination had taken place the pots were then removed to a cooler house with a temperature of 55° night, 60°–65° day, with a nice moist atmosphere which just kept the seedlings growing. When the seedlings were ready for handling the first lot was allowed to continue growing, nothing being done to the seedlings until the fall of the year when the young bulbils had gone to rest and when they were transferred to a specially prepared frame with about 7ins. of good compost and plenty of drainage. The second lot of seedlings on being big enough to handle were at once transferred to a frame specially prepared, and after pricking out, which consisted of putting into lines 4ins. apart—the seedlings being 2ins. apart—they were covered with sashlights and at night were covered with mats to prevent the temperature from falling too much, thus preventing a check in the growth.

The results of the two methods were as follows: The seedlings, which were kept in the pot until they had finished their growth, were very small but were uniform, and nearly every seedling was alive; whereas the seedlings which were handled when they were big enough were more unequal in size, the smallest being about the average size of the ones kept in the pot. There was, however, a fair proportion which had attained the size of planting out in the garden. The reason for the two distinct sizes in the pricked out batch being due to the soft nature of these seedlings and that many of the seedlings had got damaged in transferring from the pot to the frame. The seedlings which suffered were the small bulbs. In some cases the leaves were broken, in others the roots were knocked off, but in each case the result was the same. The seedlings which were undamaged were the bigger ones.

The results of this experiment were found on lifting the bulbs this October. As regards the depth these bulbs had travelled down into the soil, in the case of the seedlings which were planted out in the frame from the pot where they had been left until they had finished their growth, they were found at a depth of 3–4ins., the planting of the bulbils being 1in. at the back-end of 1922 and were of a uniform depth. The seedlings which were transferred from the seedling pot into the frame and kept growing were found to be very unequal in depth. The seedlings which were damaged had got down to a depth of 3–4ins., but the undamaged seedlings had got down to a depth of 8ins., and all the big bulbils were found down among the drainage. So that these seedlings had travelled from 1in. to 8ins. deep between the early summer of 1922 and October, 1924. Now this travel or movement of the bulbs caused me to look minutely into the matter, and I found that the big bulbs went on rooting continuously from the base of the bulb, and that when one root had attained its full limit of growth and had done all the pulling it could do, its place was again taken by another root, and so on. The bulbs had a series of roots at all different stages of development, but shortly after a root had attained its full growth it began to die, the dying taking place in nearly every instance from the tip to the base. Thus the bulb was enabled to absorb the food material, thereby increasing in size. In the smaller bulbs it is a little more difficult to see this system, but in the case of the larger bulbs the movement is quite apparent.

CORRESPONDENCE

INVESTIGATION OF WINTER THUNDERSTORMS 1925.

SIR,—In conjunction with the Meteorological Office, I purpose to continue, during this season, the annual record of winter thunderstorms hitherto made by Mr. C. J. P. Cave of Petersfield: this can only be carried out with the assistance of observers in all parts of the country. May I, therefore, ask if any of your readers would be good enough to send me, on a post card or otherwise, a note of any thunder or lightning which may be observed between January 1st and March 31st, 1925, inclusive?

A simple note of the date and time of the occurrence of thunder and lightning in any place and the direction in which the lightning was seen, especially at night, would be very valuable. Any additional information would be extremely welcome: as for instance:

(*i.*) An estimate of the severity of the storm.

(*ii.*) The time when the storm passed overhead, if it did so, and how long it lasted.

(*iii.*) Whether it was accompanied by rain, hail or snow.

(*iv.*) Direction and strength of wind; change of wind, if any.

(*v.*) Whether there was a change in temperature during the storm.

(*vi.*) Any other observation which may be of particular moment.

Reports from all parts of the country are desired, especially from Scotland, Ireland and the North of England.

On behalf of Mr. Cave, I should like to take this opportunity to thank very heartily those who last year made this investigation possible by sending their observations to him.—S. MORRIS BOWER, *Langley Terrace, Huddersfield.*

INTERESTING TULIPS.

SIR,—To all lovers of tulips Mr. Jacob's article on page 773 (November 15th, 1924) must have appealed. Never before were so many grown as now, and if observation counts for anything it is the Darwin that is most popular. He certainly sets our mouths watering by the glowing description of some of the latest, but I apprehend that the price will be prohibitive to anyone with a moderate purse, for a time. Catalogues do not often bring to our notice Sunset (rich orange), Whistler (deep blood red), Grand Monarque (plum purple), Auber (dark maroon), Rev. H. H. D'Ombrain (vermilion) or Arizona (also a plum purple). These are all old varieties, and were never, so far as my memory serves, very tall in price. I remember well Mr. Jacob sounding the praises of The Bishop, a wonderful large purple Darwin, but its price is prohibitive to-day to most people, enthusiasts of tulips though they be. This is not popular owing to the fancy price asked, which, as far as I am aware, is kept up. Mr. Jacob would assuredly have shone as a distributor of special tulips, as he places their merits

Digitized by Google

before us in such a tempting way that one could scarcely resist making purchases!

He refers to the tulip mania. Many, of course, are aware that it occurred in the seventeenth century and was not confined to the Netherlands alone, but spread to France and Germany. It would, I think, be interesting to a number who are now taking up tulip culture to read an account of how the mania originated, and Mr. Jacob could tell the story in his own inimitable way.

I wonder sometimes whether Mr. Jacob, with his "inside" information from Dutch raisers, dare lead us to hope that we may one day see a deep yellow Darwin with the stamina and shape of Mrs. Farncombe Sanders?—CLAREMONT.

ORNITHOGALUM THYRSOIDES.

SIR,—In THE GARDEN of August 23rd, 1924, you published a letter about Ornithogalum thyrsoides, which I read with great interest, as I had one bulb of O. thyrsoides coming into bud at the time. I was watching it very carefully to see if it would perfect its flower or die in the bud, as it did last year. It has recently been in full bloom, a wonderful coppery golden colour, and so delicately beautiful that it was well worth all the care bestowed upon it. It is growing outdoors on a slightly raised bed of sandy soil, where it has been undisturbed for three years.—ELIZABETH LAW, *Wellington, New Zealand.*

WHEN IS A FLOWER MAUVE?

SIR,—May I be permitted to suggest that compilers of plant catalogues, people who write for the garden Press—in fact, gardeners in general—might be a little more discreet in their use of the description "mauve"? There is a growing tendency, and has been for some time, to call anything of a bluish lavender "mauve." Viola Maggie Mott, for example, is often described as being of that colour. Even the "periwinkle blue" of the vincas is called mauve by many. That this is wrong is manifest, for the word "mauve" is French for mallow, and means, as the dictionary tells us, "a mallow colour." We must, therefore, have a lot more red in the flowers we now call mauve if the latter term is to be used legitimately and much confusion is to be avoided.—A. T. J.

GENTIANA FARRERI.

SIR,—I enclose some photographs of Gentiana Farreri and G. sino-ornata, taken in my garden in Perthshire last autumn. The lilium growing with G. Farreri is Philippinense var. Formosanum, raised from seed ten years ago. Mr. Grove wrote me some time ago saying this lilium was not a success in the South as it always got damaged by early spring frosts. With me it does not show above ground before the beginning of May and thereby escapes spring frosts. I think it was in 1923 that "Formakin" wrote to THE GARDEN saying that he could grow Gentiana sino-ornata like a weed, but could not flower it. I asked him to send me one of his plants to see if I could flower it, which he did, but there is not a single flower on it this year. I sent him a plant from my garden and when I saw him last week he told me it had flowered splendidly with him. This is rather curious as we both got the gentian from the same source. This gentian was raised from seed in Edinburgh and first flowered there in 1912. Is it possible that some of the seedlings are blind? On looking at a large patch of the gentian which was planted in a bed in the rose garden at Edinburgh, I find a good few of the plants making strong growth, but no sign of flowering, the other plants which looked very healthy but not so strong-growing were all flowering. It would be interesting to know if any other person found this gentian to be blind.—A. H.

WELL FLOWERED PLANTS OF GENTIANA SINO-ORNATA.

EUPATORIUM WEINMANNIANUM.

SIR,—In THE GARDEN for December 6th, 1924, I was pleased to notice that Sir H. Maxwell, Bt., made a favourable reference to this useful and delightful plant. When on a recent visit to the Penzance district of Cornwall I saw several such specimens as described by Sir Herbert, they were in full bloom, and it is a shrub worthy of wider cultivation. Perhaps it is not so tender as we have been led to believe. Here at Castleford, Chepstow, the extreme end of Gloucestershire, it has been in the open for several years, and each September and October it produces its masses of pinkish white flowers. Cuttings will readily form roots either in the spring or about August. In addition to being so useful for outside, it also makes an excellent pot plant, and examples in pots 8ins. in diameter are very acceptable for the greenhouse or conservatory. When grown in pots good rich soil is needed, and when the receptacles are filled with roots liquid manure should be afforded about twice each week.—T. W. B.

GENTIANA FARRERI WITH LILIUM PHILIPPINENSE IN THE BACKGROUND.

CATALOGUE DESCRIPTIONS.

SIR,—Surely in his letter to you on page 823 (December 6th, 1924) Sir Herbert Maxwell misses the point of "Claremont's" letter. Sir Herbert lays it down that "any tradesman may reasonably expect a customer to know the sort of goods he wants to purchase," and if that is so, a bare list of plant names, with prices attached, would doubtless constitute the perfect catalogue. Such a list might suit connoisseurs, who possibly number five hundred all told in the kingdom; but it would be useless to the thousands who order their plants at random from catalogues and, consciously or unconsciously, are influenced by the printed descriptions of the various species and varieties. It is an axiom of the trader's faith that the more complete a catalogue can be made the better the business resulting from it, and there is already more than one instance of the truth of the axiom when applied to the nurserymen's trade.—AMATEUR.

THE SOUTHERN BEECHES.

SIR,—*Re* the excellent articles by Mr. Bean on the "Southern Beeches" (December 13th and 20th, 1924) He and other readers may be interested to know that a fine specimen of Nothofagus Betuloides is growing at "Kitlands," a Surrey place on the Leith Hill range close to the village of Coldharbour. The tree is about 35ft. high and perfect in symmetry. I first saw it twenty-one years ago and as it is now only a few feet taller than it was then, it would appear to be extremely slow in growth in this country.

As near as I can gather the age of the tree would coincide with the 1843 introduction by Sir Joseph Hooker, who was a frequent visitor to Kitlands in those days and who probably took the young plant there himself. I have never known this tree to produce seeds, and so far as attempts to propagate are concerned the boughs are too high to layer and cuttings have never succeeded. I once tried grafts on seedlings of common beech, they also failed.

The Kitlands specimen may be mentioned in one of the volumes of trees by Elwes and Henry. I remember, at his request, sending Mr. Elwes particulars of it some sixteen or more years ago.—S. W. PHILPOTT, *Holmwood.*

ROSA HISPIDA.

SIR,—One of the most beautiful single roses in cultivation is Rosa hispida. The sturdy, yet graceful, bristly stems are freely branched and during their flowering season form pillars of bloom a foot in width and 3ft. to 4ft. in length.

The flowers are borne at the ends of the lateral branches and are yellow at first, changing to creamy white, and from 2ins. to 3ins. across. The flowers much resemble those of R. Hugonis, but the foliage is very distinct from that species. R. hispida is also very hardy, whereas R. Hugonis growing alongside was badly cut during the past winter.

There appears to be some doubt as to the origin of this beautiful early-flowering single rose, which at one time was thought to hail from America, in which country it has not, however, been found wild, and its true home is thought to be Siberia.—E. M.

NOTES FROM CONTRIBUTORS

THE WINTER-FLOWERING PERIWINKLE.

VINCA DIFFORMIS, as this plant is called, is very cheerful at this season, for it comes into flower about mid-November and "carries on" until spring. Being a native of Southern Europe, it is perhaps not quite hardy, and one will, naturally, afford a plant that blooms in winter a well sheltered place. The latter can easily be found in most gardens, for this species seems to delight in being under the protecting boughs of an evergreen, and it is an ideal woodland garden plant. Hard frost may, even in such circumstances, destroy the flowers, but the plant is so recuperative that a fresh crop will be produced as soon as the weather becomes milder.

This periwinkle has the same habit and appearance as V. major, but it is not nearly so aggressive as the latter can be. The flowers are rather smaller than those of the great periwinkle, and the lobes of the corolla are sharply pointed to one side. What the colour of the type species (if there is one) should be I know not, for V. difformis is variously described by writers of authority as having blossoms of "grey," "delicate mauve," "clear lilac" and "clean blue." One of my own plants has struck out for itself, for it is as white as a snowdrop in shade and suffused with the most delicate tint of starch blue in full sun, while another is a very pale washy lavender. Some writers differentiate between VV. difformis, acutiflora and media, but Mr. W. J. Bean ("Trees and Shrubs") appears to consider all three one and the same thing. The probability is that they are all geographical forms of the one species, some coming from Spain and Northern Africa, others from Italy and the eastern shores of the Mediterranean.—A. T. J.

THE TREE OF HEAVEN (AILANTHUS GLANDULOSA).

AMONG the many attractions of Paris are the fine trees which make her streets, avenues and boulevards a glory in the spring and places of welcome shade on hot summer days. The catalpa trees on the Quai d'Orsay are worth crossing the Channel to see in May; the splendidly grown chestnut trees in Avenue Henri Martin are lovely in spring and interesting in autumn, since several of them blossom again regularly in early September.

The beautiful trees of many varieties which are planted in the gardens which line the Avenue du Bois de Boulogne and those of the Champs Elysées (especially the magnolias of the Rond Point) are a delight all the year round.

Among the most interesting trees in Paris are the Ailanthus glandulosa which are planted on both sides of the Avenue de Wagram as well as in some of the boulevards.

These rival the plane trees as sturdy town-dwellers and are extensively planted in the streets of Continental cities. According to French authorities, they are extremely hardy in all situations, are content with poor soil, and bear intense cold and prolonged drought equally well.

The ailanthus is a native of Japan and China. In those countries it is planted round pagodas and temples, hence its name, which means "tree of the gods." The French call it "ailanthe" and "Vernis du Japon," and the Germans "Götterbaum." These trees grow rapidly and reach a great height, one of 60ft. being not unusual. The French top the lateral branches of the ailanthus every year, with the result that its trunk elongates and its branches spread out in an umbrella shape, thus giving a grateful shade in summer.

The wood is much used for furniture making. It is satiny in texture, yellow in colour and takes on a beautiful polish. The only insect which feeds on its leaves appears to be Bombyx Cynthia, and that but sparingly.

This constitutes another great advantage to the tree for ornamental uses, since its leaves are always healthy-looking. These are pinnate and are from 2–2½ft. long. They are formed of from ten to fifteen pointed leaflets, light green above and white beneath. The bark is a dark grey. The flowers are green and have an unpleasant odour. The fruit, a yellowish green samara, adds to the attractiveness of the trees in autumn. The leaves remain on the trees until the first severe November frost. Then the leaflets drop off suddenly all at the same time, leaving the bare petioles which remain on the trees for weeks longer.

A sugar is obtained by tapping the trunk of the tree. Some authorities aver that this is a cure for general debility, but there seems good reason to doubt this statement.

The Tree of Heaven is not extensively grown in England, which is a pity, as it would make a pleasing change to the everlasting plane trees in our great cities. Could not some of these trees be planted in the streets of the new settlements of hideous little houses and bungalows which are disfiguring some of England's most beautiful country?

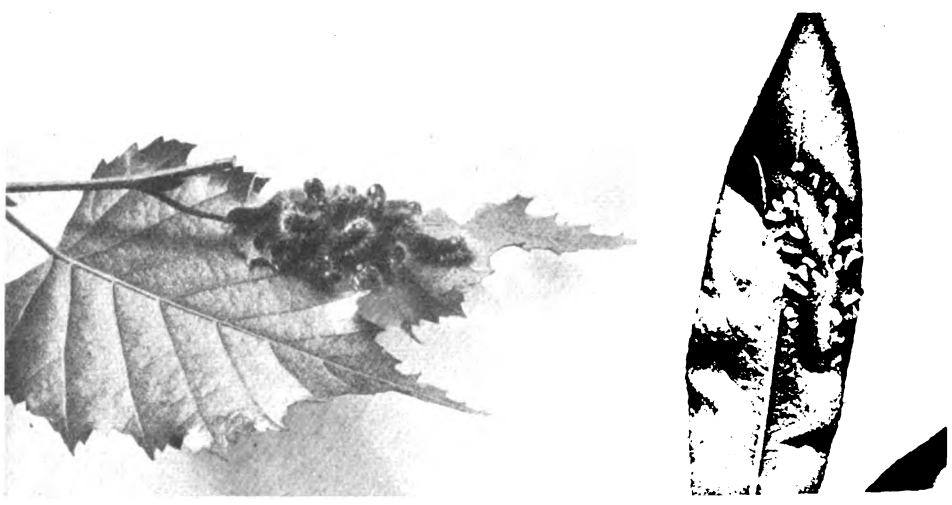
The ailanthus grows so fast—often one to two yards in a year—that it would soon tone down these hideous collections of buildings and by giving them its beauty deserve in another sense its name, "Tree of the Gods."—VICTORIA SLADE.

LILIUM MONADELPHUM.

HERE I have two varieties of L. monadelphum, which are wonderfully variable. The first of these expanded its earliest blooms on June 18th, while the other one, which has been longer in my possession, did not open much before the end of the same month. I have been more fortunate than many, as it was not long after removal to this garden that my bulbs began again to flower, resentful as they are of disturbance. In both cases I am thoroughly well satisfied with their conduct, and their beauty is so wonderful as to be a great pleasure for one to study. The first to flower I received as the variety Szovitzianum, I believe, but there seems to be so much confusion in both names and description that one becomes increasingly diffident in saying which is this form and which is the one called the type. In any case, these are truly charming lilies of most impress effective in the border, growing in some few places as much as 6ft. high and with well foliaged stems carrying a number of exquisite recurved yellow flowers of great substance. It is generally recognised that this is one of the most satisfactory of all garden lilies. One of our highest authorities on lilies advocates planting 5ins. deep, but the writer practises deeper planting than that, and has yet to learn that the shallower method is the better and more beneficial to the welfare of the plants. This old garden lily seems to have a liking for lime, but this is not essential. A good deal has been said about the spots on the flowers, and an endeavour has been made to discriminate between the plants with or without spots, but no satisfactory conclusion has been come to on the point. There is hardly, however, a really poor variety of L. monadelphum, and those who have it not will be well advised to procure it this season and plant it either in the mixed border, the lily bed or the front of the shrubbery, where it looks well against the greenery about it.—S. ARNOTT, *Dumfries*.

LEAF CATERPILLARS.

SIR,—Readers of THE GARDEN may be interested in the two enclosed entomological subjects which are herewith shown. One shows a group of buff tip moth caterpillars in their early stages of growth and the other a poplar hawk moth caterpillar from which



HARMFUL AND HARMLESS CATERPILLARS ON OUR NATIVE TREES.

ichneumon fly caterpillars have just emerged to pupate and eventually become perfect insects. Buff tip caterpillars are very destructive to birch, lime, willow and oak trees, and it seems a pity that the ichneumon fly had not missed the poplar hawk, as they are comparatively harmless. The "balance of Nature" appears to have gone wrong in this instance.—C. LACEY.

HELLEBORUS FŒTIDUS.

NO plant in the garden at this time can surpass in beautiful leafage that of our wild hellebore, and if for no other reason a few clumps are to be encouraged in the woodlands or the less important positions of a shrubbery. Helleborus fœtidus is listed to flower in March, but with the protection of shrubs and trees it will flower in February in any but the coldest of gardens. The flowers are not attractive as such, being of a greenish shade and unpleasant to smell; but, as above stated, the elegant leafage surrounding the bold 18in. high flower stalks is so striking that one quite forgets or is willing to overlook the less distinguished blossoms. Another wild species suitable for planting in woodlands is H. viridus.—C. TURNER.

A WANDERER'S NOTE BOOK

THE VENETIAN SUMACH.

THE very splendid Rhus Cotinus pictured on page 613 last year (and also, as an unusual standard, on page 575) takes me again to the shores of Lake Garda, where it constitutes the undergrowth of the woods and reaches beyond the woods to the open lakeside. In his book, "My Garden in Summer," Mr. E. A. Bowles is querulous with the Venetian sumach, in that in England it did not produce its fluff-heads in such abandoned fluffiness as in its home on Lake Garda. The two photographs reproduced in THE GARDEN suggest that Mr. Bowles had been unfortunate, for Lake Garda has nothing finer to show. Is the sumach, whose blood scarlet leaves in autumn encarnadined two miles of the valley of the Roja near Tenda in the Italian Maritimes when Reginald Farrer was preparing his book, "Among the Hills," the same species? If so, the Garda woods in autumn must out-scarlet the Roja, even as the Roja was out-scarletted for Reginald Farrer by the alpine rhamnus on the Forcella Lungieres above Misurina in the Dolomites.

OLEANDERS ON LAKE GARDA.

The note from Greece (page 767, November 8, 1924) must excite the envy of the flower—and sun—worshipper. The description of the oleander growing wild on cliff faces reminded me of the beautiful pink splodges on the precipices at the northern end of Lake Garda last June, which, viewed from the boat through glasses, puzzled me as to the identity of this superb "rock bush" until a stray seedling or two, dropped from on high to the water's edge, came so close as to settle the question. With only slight exaggeration one might say that the entire lake is rimmed with an oleander circle, but the sub-spontaneous compact bushes of the limestone precipices were more charming, and an even greater feast of colour, than the more usual but more formal, regularly spaced standards.

NAMES.

What's in a name? To me, as a wanderer, a lot. I like a name to be descriptive. It aids the memory and charms by recollection. I had lief the great botanists of old had had more regard for the useful principle of association of ideas. But botany started before Pelmanism. The primula called Juribella demands no mental effort to recall its local habitation; and once the Giuribel Alp enters your memory you are there in your dreams, with the sweet savour of the mountain tang in your heart, the more poignant for the little bitterness that you may never roam its care-free turf again. If ever I am shipwrecked on the Balearic Isles (no other chance I imagine can take me there, unfortunately), I shall know that Primula acaulis balearica lives there—the white primrose of the Balearic Isles. The beautiful deep golden auricula whose leaves are brilliantly outlined with a clear-cut white *ceinture* is more fittingly "albo-cincta," more correctly "Bauhini." Who or when was Bauhin or Bauhinus, and in what way should so ugly a name conjure up so charming a rosette, which, when first you fall in with it in the Tombéa district, leaps to your eyes as albocincta, and requires no late burning of the hotel electricity over botanical tomes to arrive at its identification? Primula Balbisii is a mental strain, but P. auricula ciliata explains its own leathery auricula leaves with hairy fringes. P. marginata is, of course, the beauty of the Maritime Alps, with broadly-margined and indented leaves. When first you see P. minima, you know it can be nothing but the least in stature of all the primulas. You do not seek P. cottia elsewhere than in the Cottian Alps. P. Berninæ takes you at once to the magnificent clear-coloured viscosa of the Bernina, where you successfully seek it in the upper reaches of the Heuthal.

THE HYBRID GEUM RHÆTICUM.

I imagine that, with many of the hybrid saxifrages, their ease and greater beauty make them *personæ gratæ* to their august collectors; but, as the greatest of rock garden apostles would have written, their origin is for the most part "wropped in a myst'ry." The roses offer another noteworthy example—from among the geums—of the value of hybrids. In early July I had admired the quite impressive abundance, floriferousness, size of bloom and clear golden yellow colour of both Geum reptans and the more common G. montanum on the Pordoi Pass, halfway from Bolzano to Cortina; and on the Italian side of the Stelvio, G. reptans could not have been bettered. I knew of the existence of their offspring, G. rhæticum, and the Pordoi appeared a likely place whereon to fall in with it; but the search yielded nothing. Later, I was prospecting the vast rocky delta that stretches out between the Cambrena glacier and the Lago Bianco fronting the hospice and the railway halt on the Bernina Pass. My excuse is that owing to the damming of the lake for the enlarged electricity works near Poschiavo, it took an unconscionable time to outflank the lake. Also the season was late and there was little to show in the way of blossom. Yet again, I had spent a longish time encircling in wonderment a vast rock as high as a cottage and longer than many cottages, that was thatched throughout its length with Primula hirsuta just out of flower. Next time, if a little earlier, I shall break my journey to pay my respects to that rock. Wherefore, for all these reasons, I merely noted that the Cambrena delta was remarkable for abundance of Geum reptans, nearly all in seed, and did not pause on my way. It was not till the other day that, in re-perusing M. Correvon's "Flore Alpine," I was stabbed with the realisation that not only is the Cambrena glacier the richest known station of G. reptans, but also that all that G. reptans is the particular form of it known as G. rhæticum of Brügger. Both montanum and reptans are starred selections for the rock garden. 'Ware montanum's tendency in rich soil to go to leafy hummocks and little flowers. Of reptans it is enough to say that doctors disagree. Some say moraine, others say no; some say rich feeding, others sandy poor and stony soil—a grievous medley, for reptans is the bigger, finer bloom. But rhæticum, the hybrid, combines the ease of the one with the splendour of the other.

THE MEETING PLACE OF PRIMULAS.

Primulas (and other plants, like the mountain lilies), are strangely local in their distribution. One valley, one species, is only an exaggeration; and it is on the windswept cols that separate the valleys that you find the hybrids. It is on the top-most cols of Judicaria that you find the meeting-place of the European primulas. To continue my diatribe on names, does not "œnensis" lack all inspiration and meaning? But Primula villosa daonensis (disowned though the name be now), is at once a description and a guide to the Val di Daone; or "stelviana," equally denounced, would make you sure of catching the sunlit ruby flash of it on the rocks bordering the motor road just where it dips below the war-desolated Stelvio Pass on its coil-like way down to deep Bormio. Does the characterless name of P. Facchini resurrect at this date the memory of a forgotten botanist more than Porta's name of Magiassonica honours this primula's home in the Val Magiassone? P. Heerii is very nearly unpronounceable, but P. integrifolia gavarnensis gives you the entire-leaved primula of the Cirque de Gavarnie in the Pyrenees, for the photograph of which (on page 435 last year) I must not omit to compliment THE GARDEN. Who was Dumoulinius that he should give his name to a primula that Gusmus called fratensis (from the Frate di Breguzzo) or Valbonæ (from the Malga Valbonæ in the same district). Where then are these little-known valleys and cols of strange names? Once you leave Switzerland by the Stelvio gate you pass south-east through the Judicarian Mountains that cluster round the peak of Adamello, on whose high passes the species meet from the four quarters of the primula world—from the West, from the Bergamasque and Bernina Alps; from the North, from the Stelvio and the Austrian Tyrol; from the long Eastern lines that stretch through the Dolomites to Carniola, Styria and Idria; and from the South, from the famous Tombéa and over Lake Garda to Monte Baldo, the botanist's Mecca, and so to the uplands of Venice. The Stelvio, the Frate di Breguzzo, the Val Magiassone, the Malga Valbonæ, the Val di Daone and the Tombéa form the primula high road in early June through this little known territory. The long jagged crest of the Tombéa, whose primulas threaten to oust all other vegetation, makes a final mass effect with spectabilis and albocincta to a route that commenced on the Stelvio with glutinosa and œnensis.

E. ÉNEVER TODD.

GARDENING OF THE MONTH

FLOWER GARDEN.

ANNUALS.—Double dig the site.

BULBS.—Keep soil round them well hoed.

HERBACEOUS BORDERS.—Tread the surface firmly round newly planted perennials after a thaw.

PROTECTION.—See that the straw has not become sodden, so excluding air from the roots.

SWEET PEAS.—Prepare site by bastard trenching a strip of ground. Add plenty of decayed manure in the second spit and a little in the first. Give a dressing of wood ashes within 6ins. of the surface and add 2lb. basic slag and 1lb. of kainit for every 30ft. of the trench.

FRAMES.—Ventilate carefully, protect with mats, water plants only when dry.

HARDY FRUIT.

BLACK CURRANTS.—Cut back hard one year old bushes.

FEED liberally with a mulch of manure fruit trees and bushes in full bearing.

PESTS AND DISEASE.—Continue spraying with caustic alkali or Woburn wash. Paint any wall fruit infected with American blight with a solution made by dissolving 4oz. of soft soap in a gallon of hot water and adding 1oz. of carbolic acid. Treat small attacks of American blight with this liquid and apply with a stiff brush.

PLANTING.—Continue with bush fruit in good weather.

PRUNING.—Continue whenever possible. Dress with tar the surface of any large cut. Burn prunings, mix ashes with loam and manure and return to the soil as a top-dressing.

RASPBERRIES.—Mulch bed at end of month with farmyard manure.

ROOT PRUNING.—Finish soon.

SOIL.—Prepare site for wall fruit. Drain the soil by placing a layer of broken bricks at a depth of 3ft.

VINES.—Prune and paint with Gishurst's compound. Top-dress the border with a compost of loam, mortar rubble and bone-meal.

VEGETABLES.

GENERAL.—Continue trenching and double digging the ground. Give a dressing of quick-lime to the soil.

BROAD BEANS.—Sow on a warm border.

CELERY.—Protect by covering ridge with dry straw.

POTATOES.—Set in an upright position in trays a sufficient number for early supplies. Place for sprouting in a light frost-proof shed.

SHRUBS AND TREES.

CLEAR from shrubberies and from under trees all leaves and dead wood.

PLANTING.—Finish in good weather.

PROTECTION.—Examine. Continue to cover tender climbers and shrubs during bad weather.

GENERAL WORK.

RECONSTRUCTION.—Continue the work.

LAWNS.—Finish re-turfing and draining. Brush regularly and roll once a week.

STORE loam, manure and peat moss litter.

WALKS.—Roll, renovate and weed. Examine drainage.

FLOWERS UNDER GLASS.

ANNUALS IN POTS.—Give final potting in 6in. or 7in. pot. Compost 2 parts loam, 1 part cow manure, 1 part leaf-soil and 1 part sand. Water with care after potting. Feed well with liquid manure.

ARUMS.—Feed continually, using weak doses of soot water and cow-manure. Give guano or Clay's fertiliser occasionally.

BEGONIAS.—Stake Lorraine type and keep a temperature of 60° at night. Take tings of this kind. Sow tuberous-rooted summer begonias at the end of the month. Use shallow pans and very fine soil. Sterilise the soil with boiling water before sowing. Mix seed with sand, scatter thinly and do not cover. Cover pans, shade and place in a temperature of 60° at night. Start old tubers at end of January in boxes 3-4ins. deep. Just cover the bulbs and put in a warm moist temperature.

BOUVARDIAS.—Feed well just before flowers open.

BULBS.—Bring into the house from the plunging ground as they are ready. Gradually raise temperature to 60° at night. Keep in darkness for a short while. Dry off gradually those which have finished flowering and stand in frames.

CALCEOLARIAS.—Give final potting at the end of the month. Put a little charcoal over the crocks. Do not bury the basal leaves. Dust with tobacco powder and guard against green fly. Water very carefully after potting, for if the new ball of soil becomes saturated the roots will not take to it.

CARNATIONS.—Strike cuttings, taken from the middle of the plant, round the edge of pots. Use a compost consisting chiefly of sand, and press firmly. Put in a mild propagating case with bottom heat. Pot up immediately they are rooted. Guard against damp.

CHRYSANTHEMUMS.—Continue to take cuttings. They do not requite bottom heat. Place in a propagating case, and remove condensed moisture daily off the glass. Pot up early struck cuttings in a compost of 2 parts loam, 1 part leaf-soil and little sand. Place them in a temperature of 50-55° Fahr. at night.

CINERARIAS.—Pot on in a compost of 2 parts loam, 1 part leaf-soil, 1 part cow-manure and plenty of sand. Dust undersides of leaves with tobacco powder if green fly present. Keep down attacks of leaf-mining maggot by killing the grub.

CYCLAMEN.—Prick off from seed-pans into boxes, water carefully and keep on the dry side and in a temperature of 50-55° at night.

DIELYTRA SPECTABILE, POLYGONATUM MULTIFLORUM AND DORONICUM.—Pot up and bring into a warm house for forcing. Increase temperature gradually to 55° at night.

EUPHORBIA PULCHERRIMA.—When flowers have finished put pots under staging for a period of rest. Give drier conditions to those coming into flower and protect from cold draughts.

FREESIAS.—Dry off after flowering.

FUCHSIAS AND HELIOTROPE.—Take out resting plants, pot up, bring into heat, syringe, and take cuttings from the ensuing growths. Give a little bottom heat to cuttings.

GLOXINIAS.—Pot up those started in leaf-soil last month.

HYDRANGEAS.—Repot old plants. Bring young plants in batches into gentle heat, water and give a moist growing temperature. Compost for potting fairly rich and containing no lime.

LILIUMS.—Top-dress L. longiflorum with dried cow-manure and sifted soil. Raise temperature to 55° at night if required early. Pot up L. auratum and L. speciosum and place in a frame. Put three bulbs in each 9ins. pot, and only half fill the pots. Do not water until the roots have started.

LILY OF THE VALLEY.—Bring in for forcing another batch from the plunge.

PELARGONIUMS.—Increase the temperature of summer-flowering varieties. Pot on when necessary.

SEEDS.—Sow in pans gloxinias, lobelia, streptocarpus, salvias, verbena, etc., and at the end of the month, antirrhinums. Shade, protect from damp and insects, and remove cover when germination has taken place. Sow sweet peas in boxes. Warm temperature needed for all these.

SWEET PEAS.—Pot up those sown in the autumn, and stake with small twigs.

FRUITS AND VEGETABLES UNDER GLASS.

FIGS.—Start now. Well water the borders. Close the house for ten to fourteen days. Keep temperature low at first, gradually raise it to 45° at night, and then ventilate a little. Syringe twice daily and damp down the walks to induce the buds to break.

MELONS.—Sow singly in 3in. pots after soaking the seeds for a few hours. Plunge in a brisk propagator with a bottom heat of 80°.

PEACHES.—Start now. Treat as advised for figs. Temperature must not be too high at first, otherwise the growths come away before the flowers, and when the flowers open they drop off. As the flower buds show signs of bursting discontinue syringing, and raise the temperature to 50-55° at night. Ventilate cautiously.

STRAWBERRIES. FORCED.—Water carefully those coming into flower, and pollinate artificially. Temperature 45° at night. Give air whenever possible, unless the temperature outside is below 32°. Leave eight to ten flowers on each plant, place in a light airy position. Feed continually with a quick-acting manure until fruit begins to colour. Bring in for forcing from the plunge another batch to form a succession.

VINES.—Start early vines. Give a good watering and close the house for the first week. Tie down horizontally rods of young vines in order that the lower buds may start into growth at the same time as the top. Syringe and damp down. Second week, raise temperature to 55° at night and ventilate a little. Prune hard back young vines struck last year. Insert vine eyes in 3in. pots in a compost of 3 parts fibrous loam, 1 part sifted lime rubble, 1 part leaf-soil. Put sand at the base of the eye. Plunge in a propagating case with bottom heat.

CARROTS.—Sow shorthorn varieties on a hot bed.

CUCUMBERS.—Sow in 6in. pots in a rich friable compost of loam, leaf-soil and old mushroom manure. Put eight to twelve seeds in each pot and cover with ½in. of soil. Place in a propagating case and remove to a cooler position when growing well. Transplant when the first pair of leaves is formed.

DWARF BEANS.—Sow in pots in a temperature of 60-70° at night. Half fill the pots with moderately rich compost. Top-dress when seedlings 3ins. high. Pinch the growing point of those sown last month and keep the atmosphere warm and humid.

MUSTARD AND CRESS.—Sow each week in boxes. Scatter seed, but do not cover. Place a piece of slate over boxes until seed germinates.

ONIONS AND LEEKS.—Sow early this month in boxes in a temperature of 65-70° at night. Cover with glass and shade with brown paper.

PEAS.—Sow in boxes every fourteen days, using different varieties each time in order to form a succession. Soak the boxes and place in a heated pit or cool house. Guard against mice. Smother seed with red lead and paraffin before sowing. When germinated remove to cooler quarters.

POTATOES.—Plant in frames on a hot-bed for early supplies.

SEAKALE, RHUBARB AND ASPARAGUS.—Bring in for forcing.

SUMMER CABBAGE, CAULIFLOWER AND LETTUCE.—Sow in boxes, add lime to the compost and germinate in a moderate temperature.

TOMATOES.—Sow main-crop in mid-January, in a temperature of 60° at night. Use a sandy compost with a little lime added, and have the boxes well drained. Cover and shade until germinated. Pot up early-sown batches.

SIMPLE GARDENING

CLEANING AND TYING PEACH AND NECTARINE SHOOTS.

TREES grown under glass are more liable to attack by insect pests than those grown in the open air, Although the former are, really, under control they are not, in many instances, kept so. During the summer months constant syringing is necessary to keep in check the green and black aphides —mostly the latter—that infest the leaves, also red spider and thrips. But perhaps the worst enemy is the brown scale and summer syringings will not have any effect on them as they thrive where clean water is applied. The present is a good time for cleaning the branches where scale is found on them. Insecticides, as advertised, may be used or a solution of soft soap and sulphur. Three ounces of the former and two ounces of the latter boiled gently for thirty minutes in one quart of rain water, will answer our purpose. Use this liquid at the rate of half a pint to a quart of clear water on the old wood only. It must not be smeared on the young buds; usually, the current year's shoots are free from scale. Apply with a stiff brush and finish the work by thoroughly syringing the branches with clear water. Remove the surface soil from the borders and lime-wash any walls. The fruits are borne on the current years shoots, these should be tied in 4ins. apart near the bottom of each tree, leaving the shoots farther apart near the centre as the centre always fills up during the growing stages. Use soft raffia or other tying material.

A USEFUL SOWING TABLE.

This simple table shows at a glance how many of the principal vegetable seeds a cultivator should order, at once, for stocking a small suburban garden.

Kind.	*Quantity of Seeds.*	*Sown in Drills or Broadcast.*	*Approximate Space Sown.*
Artichokes (Globe)	1oz.	In drills	100ft.
„ (Jerusalem)	1 peck	Tubers in drills	50ft.
Asparagus	1oz.	In drills	75ft.
Beans (Broad)	1 quart	„ „	80ft.
„ (Dwarf)	1 pint	„ „	50ft.
„ (Runner)	1 quart	„ „	150ft.
Beetroot	1oz.	„ „	40ft.
Broccoli	½oz.	Broadcast	1,000 plants.
Brussels Sprouts	½oz.	„	1,000 „
Cabbages	½oz.	„	1,000 „
Carrots	1oz.	In drills	100ft.
Cauliflowers	——	——	1,000 plants.
Celery	½oz.	In boxes	1,000 „
Cress	1 pint	Broadcast	Thickly sown.
Cucumbers	1 packet	In pots	Six plants.
Endive	1 packet	In boxes	1,000 plants.
Kale	½oz.	Broadcast	1,000 „
Leeks	1oz.	In boxes	1,000 „
Lettuces	*See* Endive.		
Mustard	*See* Cress.		
Onions	1oz.	In drills	200ft.
„	½oz.	In boxes	500 plants
Parsnips	1oz.	In drills	100ft.
Peas (Early)	1 pint	„ „	50ft.
„ (Maincrop)	1 pint	„ „	60ft.
Potatoes (Early)	150 sets	„ „	One square rod.
„ (Maincrop)	100 „	„ „	„ „ „
Salsafy	1oz.	„ „	100ft.
Savoys	*See* Cabbages.		
Shallots	300 bulbs	In rows	One square rod.
Spinach	1oz.	In drills	100ft.
Turnips	1oz.	„ „	200ft.
Vegetable Marrows	*See* Cucumbers.		

PLANTING ROSES UNDER GLASS.

Roses are more generally grown under glass now than even ten years ago, because, so grown they are better understood; there are more suitable varieties —those having long, stiff flower stems— and they are more popular, even. In a single small greenhouse one rose tree may be grown, planted out or in a large pot. It is not advisable to include the variety Nephitos in a small collection; it is only suitable for a big structure where there is ample space. Molly Sharman Crawford and Mrs. Stevens, both white-flowered, are better. Richmond is good, Liberty, too; and Hadley, a deep crimson with delightful fragrance should be included. Madame A. Chatenay must have a place; in fact, if one variety only can be accommodated, this should be the one. Hugh Dickson, although a hybrid perpetual, does well under glass; Ophelia, Climbing Richmond, Mme. Butterfly, Mrs. J. Laing, Climbing Lady Hillingdon, Souvenir d'un Ami and Maréchal Niel are some of the best. The positions for the plants should be selected now; plenty of light is essential to success and strong, not weakly, specimens to begin with. A rich loam, inclined to be sticky rather than crumbly, is the best. A naturally light loam should be improved by the addition of stiff soil, and, in every case, add some good, well rotted manure—manure rotted under cover, not exposed to rains. Bury the manure quite 6ins. below the surface. As the rooting space is, naturally, limited under glass, it is essential that particular attention be paid to providing good beds and drainage. Do not be tempted to overcrowd the plants.

GEORGE GARNER.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

PLEASE REMEMBER TO MENTION "THE GARDEN" WHEN ANSWERING ADVERTISEMENTS.

MORISIA HYPOGÆA

WHAT is, I am pretty confident, one of the most appreciated of alpine plants when in bloom is that charming plant, Morisia hypogæa. I am calling it an alpine, although, like a host of others, it does not come from high altitudes, but from the lower grounds of Sardinia. But it is eminently suited for the conditions of our rock gardens and, in common with other dwarf plants from low altitudes, may be classed as an "alpine." Its habit of growth, low and spreading (but not rapidly), makes it really an ideal plant for the rock garden, while the beauty of its prettily formed glossy leaves and the charms of its bright yellow flowers combine to give it a fascinating appearance in our eyes. Unfortunately, it has one trait which is a source of great disappointment to many. This is that it has occasionally a trick of dying off after having apparently become well established and when it gives one the prospect of retaining it for many years. I have experienced this personally and have learned from a good many others that this is their trouble also. The cause is mysterious, but, happily, the plant is propagated without much difficulty, and one can easily have a few plants in store in various stages of development, ready to replace any which may be lost. I cannot hazard an opinion regarding the cause of this unwelcome demise. But the morisia is very easily propagated by root cuttings, and also by division of large plants when carefully done. Seeds are also produced, but as these soon become buried in the soil they are often uncollected at the proper time. I have never found any young plants from seeds growing beside old ones, but in frames filled with sandy soil I have observed what appeared to be young plants from underground runners. As these were not my own plants I could not ascertain if they were from runners or seeds. But root cuttings are easily raised by cutting the roots into lengths of about an inch in autumn or very early spring and inserting them in pots with the thickest portion just at the surface of very sandy soil. In spring, growths will appear on the root cuttings and they can be potted off separately in the course of the summer. The cuttings should be put in a cool house or frame.

Respecting the cultivation of the plants in the rock garden, I have tried various composts and treatments, but what appears to suit M. hypogæa best is a very sandy soil with some leaf-mould and grit mixed with it. A well drained spot should be chosen on a sunny part of the rock garden. Although not essential, I have found this Morisia flourish best if it has frequent applications of pure water in dry weather in summer, applying this in the evening after the sun is off the plants. It appears strange to us that M. hypogæa was lost to cultivation in this country for a number of years after its first introduction, but this habit of dying off may account for this. Even with this failing, M. hypogæa is one of the most charming of the many beauties we can cultivate in our rock gardens. S. ARNOTT.

ANSWER TO CORRESPONDENT

Renovating a Mossy Tennis Lawn (D. R.).—This season has been very favourable for the growth of moss on weakly lawns. Those lawns which have been highly cultivated resist its intrusion. When the moss has gained a foothold, immediate steps should be taken to clear it away. Raking the turf is frequently tried, but it is ineffective. Its presence can generally be attributed to impoverishment or imperfect drainage, and frequently to both. It is necessary, therefore, to see that the drainage is right and the drainage pipes working well. When this is done, mow the lawn very close and apply one of the advertised moss eradicators according to directions. It generally takes two weeks for the preparation to do its work. At the end of that period most of the moss will be dead and can be easily raked from the lawn. At this stage apply chemical manure prepared to supply the deficiency which exists in the soil, so that it may be more favourable for grass growth and less suitable for growing moss. Immediately it has been applied, sow whatever grass seed may be necessary to thicken the turf. Lightly rake both of these together into the surface and afterwards mow the lawn without the collecting box being attached to the lawn mower. Continue to mow in this manner when necessary, for a time without the collecting box being attached to the machine. Avoid rolling until near the time for play, and then do it thoroughly until a fast, true playing surface is obtained.

CATALOGUES RECEIVED.

Messrs. Carter and Co., Raynes Park, London, S.W.20. Annual catalogue for 1925.

"Garden and Lawn."—Messrs. Carter and Co. have long been widely known throughout the horticultural world through their characteristic trade mark, of "Tested Seeds." Year by year, the firm has kept up with the gradually increasing knowledge in the raising of all garden produce. They have always endeavoured assiduously to maintain that high standard of excellence which characterised the energies of the firm in its embryo stages, and judging from their record of 1924, they have fully realised their aim. Their catalogue, as usual, is a comprehensive guide running to 116 pages and profusely illustrated by numerous half tone reproductions. There are a few coloured illustrations which, although not excellent, are of a high standard. A mine of useful information is contained in its pages, which will be found of extreme value and assistance to professional and amateur gardeners alike. Whether one seeks enlightenment on the raising of up-to-date vegetables in all their varieties, the treatment of lawns, one of the most important branches of the firm's duties, or the cultivation of flowers, the material is contained therein, set out simply, clearly and concisely. The catalogue indicates that one may look forward with eagerness and hope as to what the year 1925 has in store for the horticulturist.

Mrs. Grive, Whin's Cottage, Chalfont St. Peters, Bucks.—Pamphlets on Medicinal Herbs.

Messrs. Austin and McAslan, 89-95, Mitchell Street, Glasgow.—Alpines and Herbaceous Plants, also Coniferæ, Ornamental Trees and Shrubs, and Fruit Trees. Both handy guides for all gardeners in Scotland.

Royal Horticultural Society. The R.H.S. Medals.—Some misunderstanding seems to exist among exhibitors at Vincent Square as to the various medals that are awarded by the Royal Horticultural Society. The misunderstanding may arise from the fact that about two years ago the Council carefully considered the whole question of the medals and decided to allot them each to a particular purpose and not to award the various degrees of all the different medals indiscriminately. Three years ago it was possible for the various committees to recommend the award of one or other of no fewer than ten different medals to any exhibit in the hall. At the top came the gold medal and then nine others in the following order: Silver-gilt Flora, silver-gilt Grenfell, silver-gilt Banksian, silver Flora, silver Grenfell, silver Banksian, bronze Flora, bronze Grenfell, bronze Banksian. This multiplicity of medals had two results; the first was that members of the public were entirely mystified and had little or no conception as to the relative value of any of them; and, secondly, the committees got into the way of ignoring the existence of bronze medals altogether. The Council decided that for floral exhibits in the hall at Vincent Square at the ordinary fortnightly shows, it was sufficient to have four degrees, and these were to be the gold medal and the Banksian, either silver-gilt, silver or bronze. The Flora medal was reserved for Chelsea and Holland Park, where exhibits are usually on a more important scale than at Vincent Square. The Grenfell medal was kept for exhibits of botanical drawings and paintings. In the same way the Hogg and Knightian medals, which had been awarded to fruit or vegetables, were separated, and for exhibits of fruits at Vincent Square there are now four degrees, the gold medal and the Hogg medal in silver-gilt, silver or bronze, and, for vegetables, the gold medal and the Knightian medal, in the same way. Obviously, in the period of transition from the old system to the new, some exhibitors may have felt that their award was inadequate or, rather, less than they expected; but, after all, the value of an award is not the intrinsic value of the medal, but the distinction in the eye of the public which comes by the awarding of the medal to its recipient. Any visitor to Vincent Square will now see that an exhibit may receive either a bronze, silver, silver-gilt or gold medal and will know at once the value that is attached to it by the committees and council. The Flora medal was reserved by the Council for award at Chelsea or Holland Park for the following reasons: Exhibits at Chelsea are much more numerous and vary much more in importance than those at Vincent Square, and, consequently, if the same medals were awarded to exhibits in order of merit, it would obviously often happen that an exhibitor would receive a medal at Chelsea for a more important group than one for which he would obtain the same medal at Vincent Square, and would, not unnaturally, feel himself aggrieved.—W. R. DYKES, *Secretary, Royal Horticultural Society.*

East Anglian Horticultural Club.—The annual meeting of this flourishing debating and educational club was held at the Boar's Head Hotel, Norwich, on December 10th. The annual report states that the membership now stands at 226. The finances are in a satisfactory condition, there being a credit balance of £95 3s. The election of officers resulted in Mr. F. J. Endersley, The Gardens, Keswick Hall, Norwich, becoming president; Mr. S. High, The Gardens, Framingham Manor, Norwich, acting vice-president; Mr. John Clayton (Messrs. Daniels Brothers, Limited, Norwich) treasurer; Messrs. Herbert Perry and A. A. Ramsbottom, auditors; and Mr. G. R. Todd, 12, Royal Arcade, Norwich, secretary. A lengthy list of special prizes for special exhibits during the forthcoming year was announced, and also a syllabus of lectures, essays, etc., for each monthly meeting during 1925.

ON VIEWING NURSERIES

A CANADIAN correspondent has written to me about the importance of advertising plants in America. He had just returned from a tour of the States. What he says about advertising is common-sense, but that is not the point of this article. He mentions a firm in Southern Ohio which has a map of its district as a letterhead and also scatters cards broadcast with the same map and the heading, "For a nice drive follow the map." Apparently the nursery is some miles from a town. If you follow the map you find yourself ultimately driving through well kept grounds, at the far end of which is a large notice board, "This is the way out from the Hillcrest Nurseries; hope you enjoyed your drive." My correspondent remarks that in most cases people stop and ask for a catalogue and often leave an order on the spot.

Now this may be a form of advertisement which is unsuitable in this country. On the other hand, almost without exception, our nurserymen welcome visits to their grounds. Naturally, they realise that the chance of an order being given is greater when they can talk to a client at length and give him more of their time than is possible at a flower show.

Although specialists among the laity are in the habit of visiting nurseries, yet the general gardening public are slow to take advantage of this chance of seeing plants and examining them at their leisure. and this applies to every kind of nursery, whether it be that of a seedsman, or of a specialist in shrubs or alpines.

A flower show, particularly at the height of the season, is not an ideal place either for viewing or for buying plants. The ground is usually packed to the point of suffocation; the prospective buyer is so bewildered by all the plants and masses of colour around him that he does not know where to begin; while a nurseryman and his assistants do not know whether they are on their head or their heels through trying to answer a dozen questions at the same time.

In a nursery there is peace and quiet, and also room to turn round. You can see different varieties, usually in the mass, and can judge far better of their general appearance, and how they would look in your own garden. This is the case whether the plants be salpiglossis, delphiniums, roses, rhododendrons, or anything else.

This viewing at a nursery is particularly valuable in the case of trees and shrubs, for in most cases you will see fine specimens of various plants and can thus get an idea of their form, method of growth, and ultimate size. This is, naturally, almost an impossibility at a show, where lack of space and difficulties in transplanting limit the size of the exhibits. I should hazard a guess that the ordinary gardening public have little idea of the ultimate possibilities of at least 50 per cent. of the shrubs they order, which leads, of course, to innumerable cases of wrong selection and ill-placed plants.

This advice not only applies in the case of nurseries, but also to the famous botanic gardens throughout the country, Kew, Edinburgh, Cambridge, and so on. It is only too common an occurrence to see visitors walking through and admiring the plants without any thought of utilising the information to be gained from a thorough examination. There are sure to be many inhabitants which may not personally attract the visitor, or are ultra rare or are unsuitable for a particular garden, but there will be just as many which can be used. It is always a good plan to take a notebook and jot down anything that strikes the eye sufficiently, for it is almost impossible to remember everything that is admired in the course of a year.

We are always amazed at the number of requests that are constantly sent to this office for suggestions for planting schemes; for the specialist, on the other hand, the trouble is to find room for all the plants that he would like to possess. Answering these questions is always a dangerous proceeding, for we do not know the position of the garden, or soil or climate, except for vague descriptions given in the accompanying letter, and in addition we have no knowledge as to the personal predilections of the enquirer. By visiting a nursery enquirers could, at any rate, make their own choice and then ask if it was likely to prove suitable in such and such a position. Many plants have their reputations ruined by lack of knowledge on the part of a gardener who does not realise its requirements. Many a good plant is relegated to the dust heap, as being difficult or soft, when a little trouble and a personal inspection would prove that slight modification as regards situation and treatment would make it flourish like the bay tree. DOUBTS AND DISCOVERIES

BY H. A. GREATOREX.

THE EARLY AUTUMN-FLOWERING CROCUSES.

(*Continued from page* 843.)

THE Spanish group of these crocuses is rather confusing to the amateur, and it is by no means easily disentangled when one's corms are mixed and untrue to name. The difficulties turn mainly upon the variability of asturicus in its colouring and in its leaf development at flowering time, and of Salzmanni erectophyllus in its leaf development.

Nudiflorus I have never seen. Every year it is listed, every year I buy it, and every year it has turned out to be asturicus, except once when ochroleucus took its place. Its glabrous throat should make its identification easy and certain.

Asturicus is the crocus that one gets from the nurserymen to-day when one orders either nudiflorus or asturicus. Its blossoms differ from those of nudiflorus in that they possess hairy throats. It varies very much in colour. The more richly coloured forms, of a deep purple lilac with a star of dark lines at the throat and with stigmata of bright reddish orange, can be mistaken for medius; but the latter can always be separated at a glance from asturicus as soon as its leaves develop, as their midribs are of a peculiar ivory whiteness, while the midribs of asturicus are of a more commonplace silvery hue. Medius, which, although it does not come from Spain, may be just mentioned here in passing, is one of the crocuses which may be ordered with a reasonable expectation of obtaining the real thing.

Some forms of asturicus have no visible leaves when they first open their flowers, though the leaves begin just to show within a few days of the opening of the first blossoms. Others do not flower till their leaves are 2ins. or so long, and there are all grades of intermediate leaf development. The proper spathes in the most leafless forms are of a pearly whiteness, and in the more leafy specimens veined with green. I find the same relation of leaf development and colour of the proper spathes in Salzmanni erectophyllus, a species with which the forms of asturicus with broader segments and paler colour might well be confused. I have never found, however, in the throat of an asturicus the slightest trace of the yellow which seems inseparable from the throats of Salzmanni erectophyllus. Moreover, while Salzmanni erectophyllus is of about the same tone of colour as asturicus in the bud and when it first opens, the former fades comparatively rapidly, till within two days or so it closely approaches the soft colouring of Sieberi; but asturicus tends to retain its colour to the end.

Two or three of my specimens have diphyllous proper spathes, a thing which I gather ought not to be; but I have satisfied myself by dissection that they really are diphyllous proper spathes, and the plants in every other respect appear to be typical asturicus.

Salzmanni erectophyllus is the crocus which, above all others, seems to gladden the heart of the nurseryman most. Not only do I get it when I order it by name, but it is the commonest of all the crocuses masquerading as other species. Salzmannii itself I have never seen in flower. It is regularly listed and I have bought it; but it refuses to flower with me as obstinately as does the saffron crocus. The erectophyllus form is a good, robust, free-flowering crocus, and flowers profusely with me grouped round a sunken rain-water tub, in ground which is regularly sodden by the overflowing of the tub throughout the winter, and is liable to be flooded by any heavy rain throughout the year. It appears to be remarkably uniform in colour, so much so as to give the impression of being all the produce by offsets of a single corm. This, of course, is not so, as is evidenced by the remarkable variation in the leaf development of different individuals. Although on an average the leaves at flowering time are considerably longer than those of asturicus, yet it has the same leafless and relatively leafless forms. My first consignment of asturicus was, in fact, not asturicus, but the present species; and when the two groups produced identical flowers, I was at first considerably puzzled to know which species I had. I now find Salzmanni erectophyllus easily separated from asturicus by the fact that the former has a long-pointed star of pale yellow at the throat, which asturicus never has. This star is formed by the presence at the base of each segment of a narrow band or broad line of very pale yellow, extending from the throat for a little distance up the centre of the segment. I find it in every form of Salzmanni erectophyllus I have, but never in asturicus; and I think it must be a constant feature of the former species.

Once the two species are recognised it is seen that they are very different in many small details the one from the other. Salzmanni erectophyllus being less rich in colour, more clumsy in shape and, on the whole, a less pleasing flower.

I have this year received a few corms which were stated to be those of Korolkowi; but they have flowered now, and prove to be Salzmanni erectophyllus in rather an extreme form. When its first flowers open the leaves are entirely hidden, and it is not till a week or so later that the points of the leaves just begin to show. It is worth keeping by itself, for, although the flowers appear to be absolutely identical with all the others in my garden, their appearance, rising nakedly from the pearly white proper spathes, is strikingly different from that of the more leafy forms.

I see that Messrs. Barr this year list Salzmanni erectophyllus as being synonymous with Clusii. This surely must be a mistake. At any rate, all the Salzmanni erectophyllus sent to me by Messrs. Barr have been Salzmanni erectophyllus *pûr sang*. I have seen Clusii listed once or twice, and have bought it; but it always turned out to be Salzmanni erectophyllus. This year Messrs. Van Tubergen offered it,

AN AUTUMN FLOWERING CROCUS, C. LONGIFLORUS.

Digitized by Google

and I received from them two corms (all they could send). The corm tunics were a little unusual—tougher, rougher and coarser than is usual in Salzmanni erectophyllus, but with parallel fibres and no trace of the reticulations that Clusii should have. One of these has flowered. Its first flowers opened when the leaves were about half an inch long, and were quite indistinguishable from the rest of my Salzmanni erectophyllus. I fear there is no doubt it is not Clusii.

If we pass over longiflorus and hadriaticus, which we may treat as bridging the gap between the early and late autumn-flowering crocuses, only two additional early-flowering species are listed to-day, iridiflorus and cancellatus. As already mentioned, it was useless to order iridiflorus just at the end of the war, and it dropped out of the lists. It is listed again this year, and although the corms I have received are not of flowering size, there are indications pointing to its being really iridiflorus this time.

Four forms of cancellatus are listed, and there seems no disposition on the part of the nurserymen to send anything but cancellatus when it is ordered. They are all white forms with a greater or less amount of feathering except one, the form listed as var. lilacinus. This latter is not the form described by Mr. Bowles under the name var. cilicicus lilacinus. It should perhaps more properly be termed var. cilicicus. It has the long narrow segments of Mr. Bowles' form, but the anthers are yellow and not white. In other respects it varies a little in the depth of its soft colouring, and in the amount of its feathering; but it is a pretty and distinct form.

THE SOFT-COLOURED CROCUS SIEBERI.

A FINE BUT LITTLE KNOWN PILLAR ROSE

THE immunity from severe frosts has been favourable to the late blooming of this and other roses. To very many, however, Trier is quite unknown, but I can testify, after growing it for a number of years that it is one of the best pillar roses it is possible to have. When I mention that mine commenced to bloom early in June, that on November 15th there were some nice clusters, that it had never been without flowers since the first opened, its claim as a true perpetual is established, and its worth in a garden estimated. Sometimes, friends tell me of their success with rambler roses, pointing to their special favourites, but when I ask if they know Trier, their reply is invariably in the negative. Trier cannot be classed with rambler roses, whose blooming is of a fugitive character, as it is constantly throwing out flowering shoots, from fifteen to twenty flowers at a cluster. They are small, semi-double, creamy yellow, fading to a pure white, and they are possessed of fragrance, sweet as a wild rose. The foliage is of a deep green. Trier is not a rampant grower, and though it can be trained over pergola or arch, it is really more suitable for a pillar or wall.

It is at its zenith in early July, but there is little diminution of its flowering like many other climbers, as, if anyone can give it a south position, one can have blossoms continuously from June to November. It does not fill the garden with a conglomeration of shoots and suckers, like Dorothy Perkins, for instance, but is of steady growth, resembling somewhat old William Allen Richardson in this respect. I believe it was sent out by Messrs. Benjamin R. Cant and Sons, The Old Rose Gardens, Colchester, from whom I purchased it many years ago. I am of opinion, after a long acquaintance with it, that it is the most continuous blooming of all the polyantha roses, and certainly deserves a much greater recognition than is accorded it to-day.

It was recommended to me as an early and late bloomer, but it is more than this, as I do not remember a single season when it was absolutely free from flowers from June to November. Certainly. I have always been able to cut sprays in the latter month, and, on several occasions, have done so as late as Christmas. Unfortunately, not many dealers stock it, but I feel sure its merits only need a little judicious advertising to ensure for it a ready sale. I have no axe to grind in sounding the praise of Trier, I simply write of it as I have found it, as a dainty rose that gives of its treasures in clusters in charming array. It propagates freely from cuttings, and a friend of mine to whom I gave a shoot three years or so ago confirms all my good opinions of it, as the tree covers a garden shelter and in the middle of November when I saw it was full of flowers.

Does not this testimonial corroborate what has recently been advanced in THE GARDEN in reference to value of amplifying catalogue descriptions a little more? I venture to say it does. It is a fact that the great majority of polyantha roses bloom for a few weeks only—masses of flowers, swiftly followed by showers of petals thickly carpeting the ground, and the curious thing is that most people appear content with this evanescent display! I am not quarrelling with the beauty of sorts like American Pillar and Blush Rambler, and Wichuraiana roses as represented by Excelsa, Lady Gay, Hiawatha and Minnehaha, not at all; they serve a useful purpose, but what I have endeavoured to emphasise is, that a rose sent out years ago bearing the rightful name of Trier, assuredly, as it is always endeavouring to bloom, is to-day comparatively little known. It is not an exhibitor's rose, nor has it ever been, although I remember on one occasion seeing a basket among other table decorations at a show, which evoked much interest. Its chief value, however, seems to be as a pillar or wall rose, and is ideal to have round a window, where its beauty can be admired in the late autumn days, as well as in the first flush of summer when the buff orange buds expand in petals of creamy yellow with anthers of gold.

As I said in my note in THE GARDEN of November 15th last, under the heading of "Catalogue Descriptions," it should be remunerative (to the advertiser) to enlarge upon the merits of older plants, and that one of the reasons why some plants have little sale is because they are lost for want of proper advertising. This rose is a case in point, as many would be pleased to welcome it in their gardens, did they but know of its simple charm, and the long period over which it reveals its beauty.

CLAREMONT.

TREES AND SHRUBS FOR AUTUMN FOLIAGE

IN THE GARDEN a short time ago there was an interesting and descriptive list of trees and shrubs which provided rich autumn foliage; to that list many others can be added. In the following notes I am supplying a few more, all of which have been much admired for the past two or three months.

The first touch of autumn colour last year was seen on the North American Ribes prostratum, which, as its name implies, is quite distinguishable on account of its low habit; it keeps near to the ground and the foliage attains the richness of R. americanum, which your correspondent quotes (I was also impressed by the same exhibit). R. Menzesii, which belongs to the gooseberry section and grows into a stout bush, also gave a luminous display of foliage. Resplendent as was the foliage of Euonymus planipes, latifolius and yedoensis, the first euonymus that gave colour was E. americanus and its var. angustifolius, both a purplish red colour. It is a somewhat loose grower and to keep it above ground it should be given support; the weak growths if tied loosely have a pendulous appearance. E. Maackii was reticulated with yellow and red. The euonymus that gave me most pleasure was E. Bungeanus, as the foliage turned from pale green to delicate cream, with a suffusion of pink on both foliage and fruits producing quite an unfamiliar autumn colour. It is a Chinese species 15ft. or more high. The leaves having long petioles and hanging loosely it is most ornamental, but fruits are produced sparingly. Not any foliage that I have seen surpasses the brilliancy of Rhus trichocarpa, a small tree with pinnate leaves which assume a dazzling radiance of cream, gold and scarlet. Those who are in possession of this plant must get into a state of ecstasy if it colours with them as I have seen it. Owing to the poisonous nature of some rhus there is a certain amount of risk if the foliage is handled; personally I have not suffered by so doing. Perhaps this rhus is not easily obtained, and I do not know if it can be propagated by cuttings, but plants can soon be raised as Japanese seed germinates freely, and the seedlings make 6ins. to 9ins. of growth in a season.

With all the commendation of Acer Ginnala and the palmatum varieties, A. grandidentatum qualified to usurp them this season. The latter is a west North American species with fairly stiff habit and foliage which turns to hues of yellow, red and greenish purple before any of the other acers. I must endorse the high favour bestowed on Fothergilla monticola, so handsome has the foliage been in a galaxy of yellow, scarlet to crimson, but growers must bear in mind that these colours do not always develop when growing in deep rich loose soil. F. Gardini, by the way, is a smaller shrub and has not the same glow of colour, but a sheen of purplish crimson comes through the green. Gleditschia aquatica var. elegantissima, which is quite another type of small-growing tree, is rounded in shape and interesting, as all the foliage seemed to turn colour from pale green to yellow simultaneously, but, alas, fell off just as quickly. I believe pinnate leaves with small leaflets are addicted to this fault.

Æsculus glabra, an American chestnut well known in its own country for autumn splendour, does not belie itself in this country, fairly large specimens giving a sumptuous display of glaring shades of red and yellow. I was about to write that it is the best of the chestnuts had I not some notes on Æ. glaucescens, which to me seems a glorified Æ. octandra, not only was the foliage exceedingly fine in a scheme of yellow and amber with enough red to give it a real artistic appearance, but it also unfolds, in the spring, foliage of a lovely colour. The summer dignified Himalayan Æ. indica shed its leaves without the least touch of colour. Certain oaks we are well acquainted with, but little has been mentioned of such as Quercus glandulosa, which early last October was pre-eminent, the foliage being lustrous red and noticeable from a distance. Nor less striking was Q. Leana, while young trees of Q. alba and marylandica, both from the east United States, tried to excel one another in their garb of super golden bronzed foliage. All the "Pignuts," and especially Carya sulcata and alba, at the end of October were majestic with their heavy load of golden foliage. Magnificent is the word for such trees in this grandeur. Some of the pinnate leaves were 2½ft. long, and opposite leaflets, when measured outstretched, were 23ins. from tip to tip. Oh, that there were more of those noble looking trees in cultivation! I feel certain Americans would be only too pleased to stimulate interest in this genus.

I do not know of any deciduous rhododendron to eclipse R. dilitatum, which has intensely red foliage, but recognition must be given to R. Tschonskii, a small virgate bush which becomes yellow and reddened. Among the azaleas no other species helps to enliven their choice colours so much as the common R. (Azalea) flava-pontica. Another twiggy ericaceous shrub is Elliottia paniculata, a Japanese shrub which possibly engages attention more when in flower, but it deserves inclusion in these notes as the foliage was quite gay in the late autumn. Vaccinium simulatum, a North American species which I am not certain about, but believe it to be near V. stamineum, is worth booming up, for the foliage becomes intensely red over every part of the leaf. Disanthus cercidifolia, a shrub quite hardy and greatly in request, should be in all collections where autumn foliage is a consideration. I first saw this shrub in flower early in 1918. It should be more often seen, considering propagation is easily effected. Cuttings taken in June from short shoots, 3ins. or so in length, inserted in very sandy mixture and kept in moderate heated cases, root and are ready for potting in six weeks. Plants in their permanent positions should never lack water, for too dry a position is much against their well-being. C. F. C.

TREILLAGE

A USEFUL ADJUNCT TO THE GARDEN WHEN IMMEDIATE EFFECT IS REQUIRED.

TREILLAGE is one of the most useful materials at the disposal of the garden architect, and it is gratifying to find that it is growing steadily in popular favour, as its immense possibilities become more widely known and appreciated.

The word "treillage" has been defined, I think, to mean trellis which has some pretensions to architectural treatment, but it will be sufficient if we consider it to imply some better conceived structure than the cheap lattice of the ironmonger: if, in short, we regard it as something which has been specially designed to meet some special need.

In the average garden there are countless ways in which trellis can be employed, and if it be used with care and discrimination, many beautiful and varied effects can be contrived.

One of the most charming ways of utilising treillage is as an alternative to the hedge, where rose or other special gardens need to be enclosed. Perhaps its greatest advantage is that, once erected, an almost immediate effect is obtained; and when, after a year or two, climbing plants have established themselves, the whole bears a finished appearance which the lapse of many years would hardly give to a yew hedge. Financial considerations are important ones nowadays, and it will be found that trellis compares favourably with hedges in the matter of cost, especially when the expense of trenching and manuring the soil is added to the price of the plants of yew, cupressus or thuya. The trellis, of course, cannot give you that sense of dignity and repose which seems inseparable from a fine hedge; but it has a grace and an airy charm which are peculiarly its own.

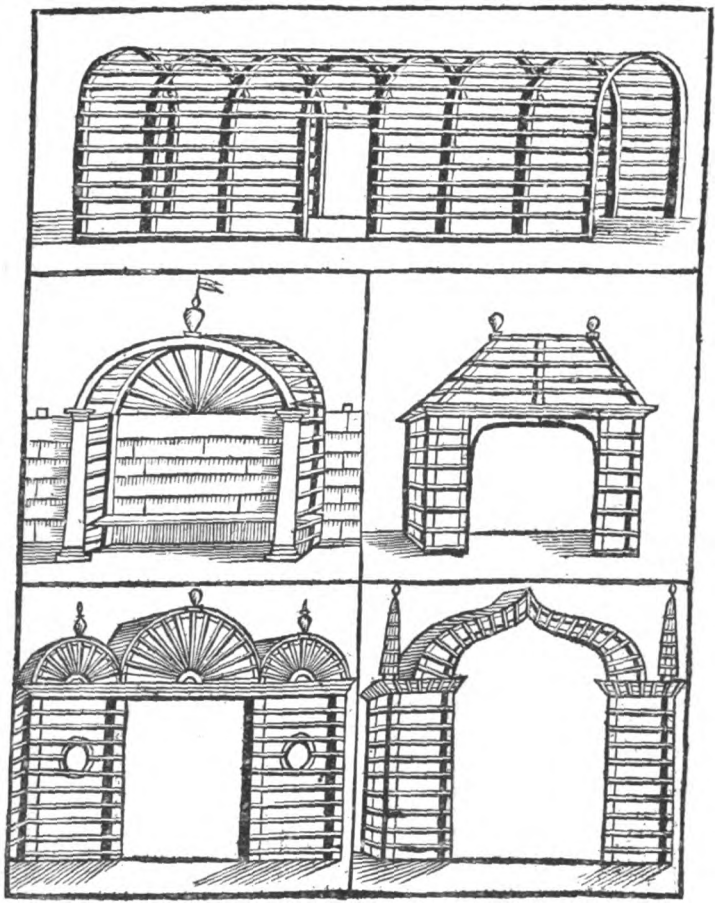
In its simplest form the trellis enclosure would be from 6ft. to 8ft. high, supported on stout posts, and made with a square mesh of, perhaps, 6ins. to 9ins. across. This could be put up easily enough by an intelligent and handy labourer; but for the more ambitious designs in which the top line, instead of running straight, is scalloped between the posts, or in which combinations of square and diamond meshes occur, it would be

Digitized by Google

prudent to enlist the services of a good horticultural firm. One or two of these firms make a speciality of treillage, and may be depended upon to carry out carefully either their own or their customers' designs.

Another beautiful use to which trellis can be put is as a facing to walls or fences. Very few fences and not all walls are really pleasing in themselves, and there must be many gardens in which an arid stretch of wood or brick could be covered with a simple form of trellis and planted with one or two good climbing plants. Estheticism apart, there are practical advantages in such a scheme, for in hot weather many plants appreciate the inch or two of air which lies between the woodwork and the baking wall. In addition, most climbing plants can support themselves on treillage, and the exceptions can be fastened more speedily to the laths than to a wall or fence.

Little arbours made of trellis look extremely well, and while their light construction makes them a rather precarious refuge from heavy showers, they afford wonderfully cool and airy retreats from the summer sun.



EXAMPLES OF SEVENTEENTH CENTURY DUTCH TREILLAGE

In large gardens the gazebo or garden house takes the place of the arbour, and although these are, in many cases, massively built of brick or stone, roofed with tiles and fitted with elaborate doors and windows, it is questionable whether a better effect could not sometimes be obtained by supporting the roof on brick piers and filling in the intervening spaces with trellis.

The wood most generally used in the construction of treillage is oak. This is a wood which always looks well, and it can be preserved for many years by treating it with Solignum or some other good stain, which in time will weather to a silvery hue. Deal might be used with success in gazebos or other structures where it would have a certain amount of shelter from the weather, and would look well if painted white or a glaucous green.

Some mention should, I suppose, be made of rustic trellis. Usually, this is objectionable to a degree, particularly if it happens to be of the "ready-made" type. Most of it is made of horribly contorted branches, varnished to a quite unnecessary brilliance, and ought not to be tolerated anywhere. I wonder how many miles of this stuff are sold every year? A great many, I should imagine, if the advertisement pages of the gardening Press are any criterion.

The manufacturers, naturally, are far less blameworthy than those people whose insistent demand dictates a constant supply of these cheap and nasty creations. The firms would be only too glad to sell something better if their patrons would let them.

In small gardens, however, where an architectural note need not be struck, a trellis of light poles is quite permissible. A structure such as this could be built of any suitable wood, but unpeeled larch looks as well as anything. A preservative stain should be applied to the ends of the poles which are to be inserted in the soil, and this precaution will add years to the life of the trellis.

D. G. S. HOOK.

SHORTIAS, CHARMING WOODLAND PLANTS

THESE very choice little evergreen plants call for rather more than ordinary care if one would be sure of success; but, providing a suitable position is chosen, and their requirements met regarding soil, there is no reason why such plants should be seen so rarely. Apart from their exquisite flesh-coloured, fairy-like flowers in spring, the foliage is more or less beautiful at all times, though it is in autumn and winter that the rich bronze or reddish leaves are of an exceptionally fine colour. The open woodland provides the ideal home for the shortias, but it is not everyone who is fortunate enough to possess such a restful adjunct to his garden, therefore the rock garden must be considered as taking second place; in any case, the treatment is similar. Choose a moist yet well drained position in partial shade at the foot of the rocks, or if in the woodland, on the fringe of conifers but clear of the drip from deciduous trees and near to a frequented walk, as it is as well to have such rarities under constant observation. Should the existing soil be heavy or poor in humus it must be entirely excavated to a depth of 2ft., or more if drainage be considered necessary, but avoid digging a well for surface moisture to drain into. This can be accomplished by selecting a somewhat raised mound or bank, digging out and breaking up the soil to the lower surrounding levels. Natural drainage will then be assured. Place a layer of broken peat turves in the bottom, finally filling up to about 6ins. above the original ground level with a good free mixture of peat, loam and sand. Half-decayed leaf-mould can be used instead of peat with almost if not quite equal results. Tread the compost in firmly while it is new and dry. All will then be ready for planting, which is best done during a mild spell in spring. Should frost or cold wind set in immediately after planting it is advisable to protect with evergreen branches or other material. In the actual planting see that the plants are put down to their original level and fine soil worked in round the root stalks, and make firm by pressing inwards to the root stem, not downwards, or the fine roots may be stripped off. Established plants from pots are naturally easier to deal with, but even in this case the ball of soil or roots must not be interfered with, as they resent disturbance. The well known North American species, S. galacifolia, is the easiest to grow, also to procure, as it is fairly plentiful in this country, and when once established under ideal conditions will quickly form spreading clumps. It is sometimes possible to obtain good pot-grown plants of the rare Japanese S. uniflora, but this plant is much scarcer than the former, which it resembles, except that the leaves are smaller. The most beautiful of all, however, is the form called S. uniflora grandiflora; this is a most lovely thing with large, wide-open, pale pink blossoms on 3in. or 4in. stems, while the foliage, too, is quite distinct, being almost round and smaller than in the type—or is this latter the type plant? as R. Farrer in his "English Rock Garden" seems to have thought.

Propagation is generally by division, but unless one is really hardened to these more difficult plants it is better left alone, for they are all too scarce. I wonder if any reader has raised stocks from seed? I have harvested and sown seed of S. uniflora grandiflora, but so far without results, none having germinated.

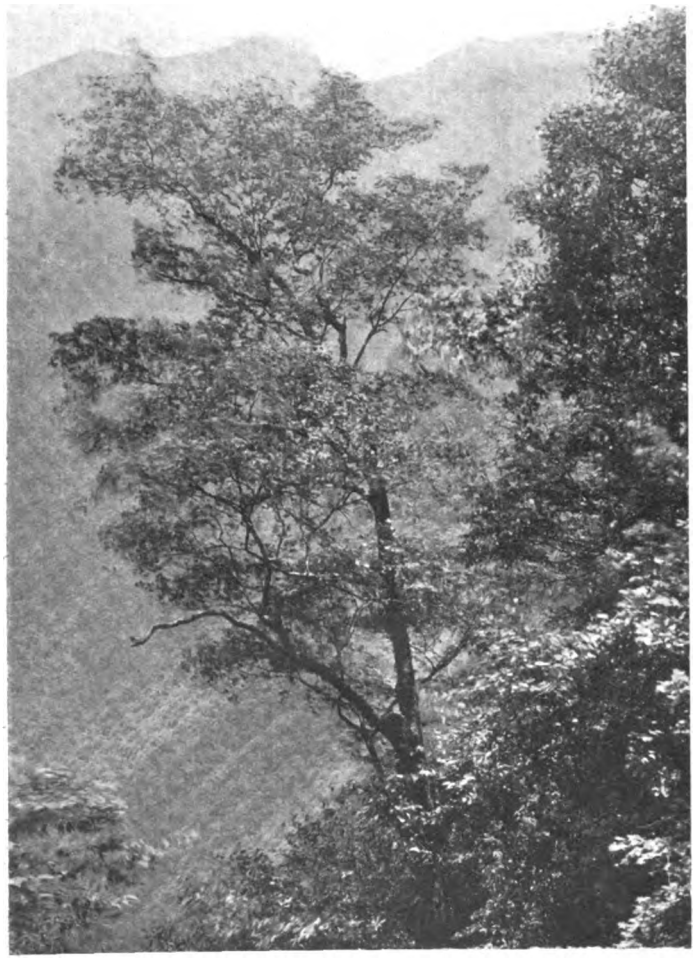
ACER GRISEUM

BY E. H. WILSON.

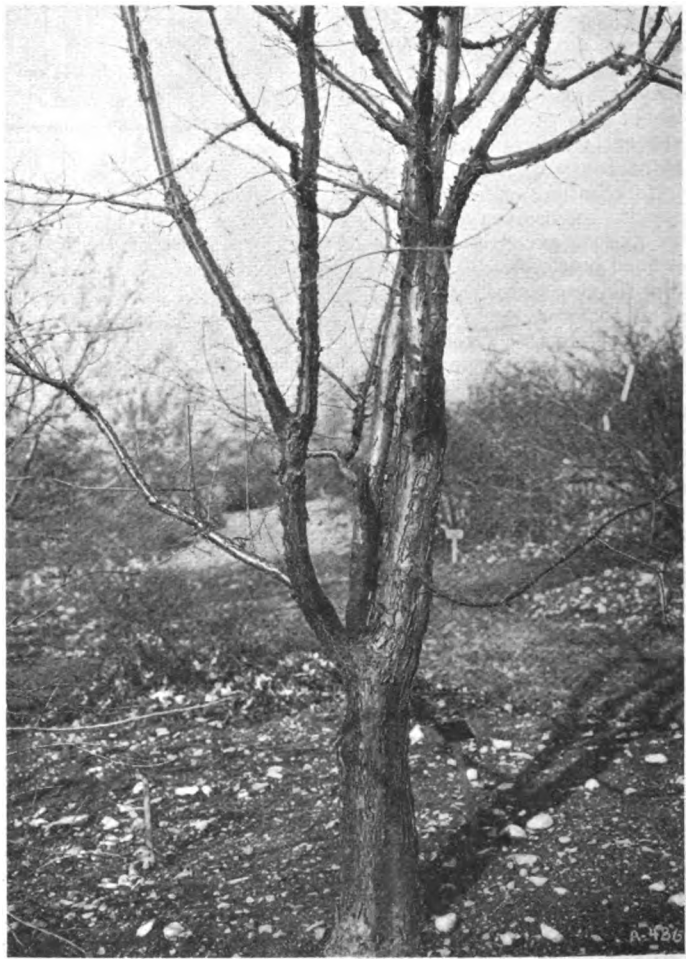
IN his article on "Supply and Demand" in THE GARDEN for November 15th, 1924, the Editor makes use of a rare Chinese maple (Acer griseum) to illustrate his point of view. As the person responsible for the presence of this tree in Western gardens I read the argument with zest. Quite as an after thought it occurred to me that the story of this maple might be worth setting down.

It was in May, 1901, that I first saw A. griseum and straightway became captive to its charms. Looking over my notes I find the terse statement—"Hupeh's best Maple." Now, twenty-three years afterwards and with fuller knowledge of the flora of Eastern Asia, I do not find my judgment at fault, though it might be enlarged to read "China's best Maple." forests of north-western Hupeh and contiguous Szechuan, but recently it has been found in Northern Honan. It was discovered about 1892 by Père Farges and was first referred to A. nikoense as a variety, later it was raised to specific rank.

Unlike many Chinese maples A. griseum has taken kindly to the climates of Europe and eastern North America. In the Arnold Arboretum we have three plants. One was nearly murdered during the winter by field mice which gnawed through the bark for four-fifths the circumference of the trunk. The other two are lusty young trees which have flowered and fruited for several years, but, alas! have borne no fertile seeds. They have never suffered winter injury and have smilingly endured



ACER GRISEUM IN THE FORESTS OF CENTRAL CHINA.



THE MAHOGANY RED BARK OF A. GRISEUM.

With its shining mahogany-red bark, thin, peeling and curling to display smooth, polished, orange-brown patches on trunk and branches, this species is unique among the fifty odd species known from the Flowery Kingdom. Throughout the winter it is one of the most attractive trees I know and in the spring, as the sap rises, its stems fairly glow. The leaves are three-foliolate, relatively small, irregularly toothed, clothed with long pale grey hairs on the undersurface and as they unfold are ruddy bronze in colour. Soon they become nearly smooth, green above and light grey below and in the autumn are gaily tinted orange to scarlet. The flowers are yellow, borne in small clusters and are followed by the usual key-like fruits. Everything about this tree is pleasing, but over and above all is the beauty of its bark.

This maple is usually a tree from 30ft. to 45ft. tall with a trunk from 3ft. to 4ft. in girth; the finest specimen I have seen was 60ft. tall and 8ft. in girth of trunk. Its home is moist rich woodlands between elevations of from 4,000ft. to 5,500ft. A rare tree, this maple is known to me only from the as much as 50° F. of frost. So English gardeners need not worry themselves about its hardiness. The drawback is the difficulty of propagating it. I know of a plant raised by layering, two by grafting, but no more. Even in China the tree does not bear fertile seeds every year. In 1901 I secured a good harvest of seeds, from which Messrs. Veitch raised one hundred plants. In 1907 I collected other seeds, but in the Arnold Arboretum we succeeded in raising one plant only. Fortunately a few seedlings were culled from their mountain home and safely transported to America.

There is an old saying that "Good wine needs no bush," and this is true of plants, but their merits may long remain unknown to many garden lovers unless some friendly scribe sets forth their charms. Collectors of new things must be wary how they descant upon their finds, or they may injure where they would bless, for the world is sceptical. And so a decade or two may easily slip by before the qualities of a plant become properly known. Such has been the experience of this handsome maple.

PLANTS I HAVE KILLED

BY DR. R. LLOYD PRAEGER.

THE TITLE EXPLAINS THIS ARTICLE. DR. PRAEGER IS FRANK AS TO THE LIMITATIONS OF SOIL AND CLIMATE IN THE SUCCESSFUL CULTIVATION OF ROCK PLANTS. THE TROUBLE WITH THEM IS NOT ALWAYS ONE OF HARDINESS OR WRONG TREATMENT. OFTEN THEY SIMPLY REFUSE TO GROW HOWEVER WELL YOU MAY TREAT THEM.

WAS it Frederick the Great who used to greet a new physician with the enquiry, "Well, how many graveyards have *you* filled?" Were the same gibe addressed to me, I could, like many another rock gardener, only bow my head. For, indeed, unless one is satisfied to lie ignobly at anchor in the safe haven of London Pride and Periwinkles, casualties are frequent on board, and one's course is punctuated with burial services. A dim perspective of beloved ghosts stretches behind one, ever lengthening as the years roll on. I am not referring now to such notorious fade-aways as Hudsonia ericoides or Eritrichium nanum or Saxifraga florulenta or Schizocodon soldanelloides. There is no credit in killing them—any fool can do that. If one has any enterprise at all, the list of things that one has loved and lost is a long one: it gives rise to many conflicting thoughts; and a little meditation upon it is a salutary exercise, and conducive to humbleness of mind.

As in most problems of gardening, it is difficult to generalise on this matter, because one's failures are in considerable measure dependent on the conditions of soil and climate under which one works. So as regards personal reminiscences in the remarks which follow, it is necessary to premise that my domain consists of a small suburban Dublin garden, with a mild climate (though not very mild for Ireland) and a light loamy limy soil. The limitations of such a garden are obvious. Save in pockets of peat, no ericaceæ will survive except for the few precious things, like Rhododendron hirsutum and Erica carnea, which do not care where they grow. No damp-loving plants either, like Ourisia coccinea and many species of mimulus. But indeed, as regards plants of wet places, I have been more surprised at the things that contrived to live than at those which gave up the attempt. The marsh fern, Lastrea Thelypteris, appeared in some mysterious way in a clump of Anthyllis montana—the one a plant of soaking swamps, often under water for half the year, the other from the hot rocks of southern Europe; and they still live amicably together. The graceful Carex Pseudo-cyperus, another "wet" plant, wanders about the garden (by seed), looking for a spot moist enough to settle down in, and never finding one.

Every gardener has, of course, his list of plants which he longs to grow but which are just too tender for the particular climate with which he is afflicted. We in Ireland are, in general,

GALANTHUS ELWESII WILL ONLY GROW WHERE IT CHOOSES.

well off in this respect as compared with our English and Scottish neighbours; but, just as no one has quite as much money as he considers he ought to have, so everyone's climate is just a degree or two too cold. Among the plants which will grow here for a few years, only to be destroyed just when they are beginning to look really happy, are Dendromecon rigidum, Sollya heterophylla with its pretty blue flowers, Billardiera longiflora with its blue berries, Cineraria lobata—a gay little thing never out of flower—Senecio leucostachys, and many others. Their decease is always the more regretted since all are quite hardy only a few miles away, down by the sea. But, after all, there is no reason to repine: it is our first duty to learn our climatic limitations and to accept them; "there's lots of good fish in the sea," and we need not don mourning.

More annoying in reality are those plants which will grow with you if they choose, and won't if they don't. That is all there is to it, as the Americans say. There is no use in coaxing them or coddling them, or providing them with complicated composts or ideal nooks. If they won't, they won't, even though they may flourish like weeds in a neighbour's garden. The plants which come under this woeful category no doubt vary in different parts of the country. Visions of Iris reticulata arise in my mind in this connection, to quote only one example; and I think many people would add Gentiana acaulis (so-called).

Then there are the curious instances of plants which will grow in one's garden where *they* choose, but not where *you* choose. With me, Iris hispanica rapidly died out everywhere it was planted, but sowed itself between two blocks of stone, and, tightly wedged in, it increases year by year. Galanthus Elwesii behaved similarly, choosing its own apparently very unsuitable home.

Much more distressing than these are the plants which are equally unwilling to live or to die. An excellent—or rather, horrible—example of this with me is the citrange, a hybrid citrus sent out for experimental purposes some years ago by the United States Department of Agriculture. I never look at it without thinking of Calverley's parakeet:

He'd look inimitable stuff'd
And knows it—but he will not die!

GENTIANA ACAULIS IS OFTEN AS STUBBORN AS A MULE.

Digitized by Google

Every spring it pretends to start growth, and then changes its mind. Like Wordsworth's thorn,

> No leaves it has, no prickly points ;
> It is a mass of knotted joints,
> A wretched thing forlorn,

and every season it looks more disreputable and more dissipated.

In contrast to these, there is a group of plants which flourish exceedingly for a while, and spread ravishingly about the garden ; after some years they diminish and finally disappear, and no matter how often re-introduced, refuse to repeat their first delightful performance. I fancy that the species which do this vary to some extent in different districts ; with me Linaria alpina and Papaver alpinum were noteworthy instances. The meaning of this phenomenon has always puzzled me. One theory is that the plant exhausts a certain quality of the soil ; that seems unlikely. Is there a diminution in vigour in the successive generations, just as in the case of some newly introduced species there appears to be an increase, or at least a change rendering them more suited to the new conditions ?

Again, there is the question of slugs, a race which has more murders to its discredit than the worst of the Cæsars or Borgias. But here again there is discrimination. Not only are some slugs more destructive than others (one species, indeed, preys upon its fellows, and ought to be encouraged, like those of the genus testacella which live on earthworms), but they attack different plants in different gardens. There are some plants, indeed, which are gobbled everywhere unless protected, like Phyteuma comosum ; but many others are persistently eaten in some places, and never even nibbled in others—another phenomenon worthy of investigation. Of one thing, however, we may be sure—slugs will always tackle a new plant, and the rarer it is the greater their anxiety to sample it. Mortality may be reduced considerably by putting a zinc ring round every new small prize : it will keep off not only slugs, but many things besides.

I find I have been prowling round the fringes of my subject, between the living and the dead, without the courage to enter the main cemetery at all. But it is before my eyes all the time, populous with lost treasures—primulas and gentians by the dozen, dainty alpine androsaces and campanulas and phyteumas, stiff little Lewisias and silvery tiny artemisias ; æthionemas, violas, pentstemons, and what not. Each for a while has gladdened my heart,

> . . . and anon
> Like snow upon the desert's dusty face
> Lighting a little hour or two—is gone.

Things from Chili and from China, whose want of hardiness was conveniently excused in nurserymen's lists ; North American plants, whose need of peat was modestly concealed ; high alpine gems that even under the most skilled treatment are short-lived in our uncongenial lowland gardens, though venerable with age among the snowy crags ; each in his narrow cell for ever laid, is now but a memory. But experience brings wisdom to all who know how to learn, and knowledge foreshadows success ; many deaths have been redeemed by subsequent success. There is no use trying to grow a difficult plant till you have found out all you can about it—what country it comes from, what climate, what elevation—if possible, what soil. Then you will have something to go upon—some idea where and how to plant it. But for all rock plants (and it is they in particular of which I am thinking), deep drainage above all things, and a light soil. And there are two fortuitous and unsightly aids which will save many a life : one is the zinc ring already mentioned ; the other is for the woolly-leaved treasures that damp off in our abominable winters—a triangular piece of glass pushed into the earth close to the plant at an angle of 45°, so as to form a kind of roof. This has a surprising effect on such things as Asperula Athoa and the tiny androsaces.

But many of the loveliest of the mountain nymphs will not come to us : it is we who must go to them, to the infinite benefit of both mind and body. There, on the wide-flung crags, to see them is an education in itself, and brings an uplifting of the heart such as few things can give ; but in our gardens they languish and pine, and in spite of all our loving care, one day we find them gone. *Requiescant in pace !*

A HOUSE FOR SEEDLINGS

A STRUCTURE TO MEET THE REQUIREMENTS OF THE HYBRIDIST AND RAISER OF CHOICE PLANTS FROM SEED.

PLANT breeding is a fascinating pursuit, and whereas in time past it was, generally speaking, looked upon as the prerogative of the professional expert and the *élite* among trade specialists, this particular phase of horticulture has to-day irresistible attraction for a large number of keen amateurs whose chief ambition is to raise and introduce to cultivation " something new " that shall be welcomed as a valuable addition to whatever may be its particular class of plants.

Seeds are divisible into various classes or groups, but while there are those which may best be sown in the open ground and others for which a hand-light or garden frame will afford ample protection, there are many for which a greenhouse is necessary. Under this category must be included not only the seeds of what are usually termed " greenhouse " plants, but a wide range of small seeds of plants which are hardy when fully developed, but fragile in the juvenile stage, seeds which are very slow of germination, seeds which are the result of crosses between distinct species and the constitution of which cannot be foretold, and seeds which have been collected in foreign habitats or have been imported from distant sources, and may quite possibly have lost some degree of vitality during the period intervening between harvesting and sowing.

The owner of an ordinary greenhouse may find its capabilities quite equal to his requirements so long as he simply sows the ordinary range of garden seeds, and it would be folly to suggest that every garden should possess a special seedling house. The plant-breeder, however, simply cannot afford to risk the loss of seeds or seedlings for the lack of a suitable house in which to bring the results of perhaps years of patient labour and endeavour to a successful issue. That is the justification I have to offer for touching upon an unusual theme.

Let me disclaim any capability as a carpenter or builder, lest my readers expect me to disclose subtle secrets of the craft that shall enable them to build a perfect house at a minimum expenditure of cash and labour. Let me rather tell what I as a grower and propagator would wish my seedling-house to be, and indicate the faults and blemishes I would wish avoided in its design and construction, and leave it to cleverer men of tools than I to put these recommendations into material shape.

First, let the choice of situation be considered, for a perfect seedling-house in the wrong position will immediately lose its perfection for practical purposes. Seek not a position exposed to full sunshine, for that ranks among the worst aspects for a seedling-house. Avoid overhanging shade, or trouble lies ahead through precious seedlings being drawn up weak and spindly. A northern outlook is admirable *if* the position is well sheltered from biting winds but is open to unrestricted daylight. Where a northern exposure is too bleak, choose west in preference to either south or east. The former is too hot, and the latter has the disadvantage of catching early morning sun, sometimes a very material disadvantage where tiny seedlings are concerned. The house may be a lean-to, for if a good wall is available it will be more economical.

In regard to the ground it stands upon, if the soil is heavy and wet, excavate a reasonable depth and make a floor of porous rubble, clinkers or ashes. A cemented or tiled floor is an advantage, helping to minimise the risk of development of moulds and fungi, such floors being easily scrubbed and cleaned. While attention is directed to the floor, let me urge that it should slope slightly toward a shallow gutter leading to a good drain. Every possible means should be devised to ensure freedom from stagnant moisture, for puddles

Digitized by Google

on the path or under stages are fruitful sources of trouble.

For the roof use broad glass, reducing the number of rafters, for the woodwork casts shadows and tends to cause drip, a bugbear to the seedling raiser. I know, alas! of no drip-immune rafter; but to minimise the trouble the roof of a seedling-house should have a fairly steep pitch. That is one point that has before this been argued on the ground that because seedlings require to be kept near the glass the roof must be low and pitched at a broad angle. My retort is that other and better means are possible of keeping seedlings near the glass.

There is no necessity for upright front lights to a seedling-house. The roof should rest on a short front wall. The ends of the house should be glazed, if possible, but if the position of the house is in a corner one end may of necessity be opaque. Corner positions, however, are only good when they afford shelter without curtailing daylight.

Roof ventilators should be small and numerous, arranged not in one continuous row along the top of the roof, but alternately at the top and midway down the roof. There is a reason for this which may here be explained. In view of the importance of keeping the staging of a seedling-house as near the glass as possible, the pathway and door will be situated midway between the front and back walls. The front stage will be flat, and upon this newly sown seeds will stand. The back stage will start at a higher level and be arranged in tiers, the top tier being virtually a shelf along the back wall. If the only ventilators are at the top of the roof it may frequently happen that a cold, cutting draught drives right on to the seedlings on the top shelf, whereas that can be avoided by opening the mid-roof ventilators which will not have a shelf so immediately under them.

Ventilators may also be put in the upright ends of the house and a row of box ventilators along the front wall. The more the means of ventilation can be distributed the easier it will be to admit air without cutting draughts, simply by opening on the leeward side.

The front stage demands special attention, for here actual germination is to take place. The best material for this stage will be square perforated tiles such as those used for malt-kilns. They should be laid on a framework of iron strap bars 1in. by ¼in., and at the front of the stage an edging of about 4ins. depth should run the whole length, the object being to hold a bed of coconut fibre in which to plunge the seed-pans.

The hot-water pipes for this house should all be under the front stage, the flow pipe along the wall side, the return near the path. This gives the advantage of slight bottom heat for such seeds as require it to help germination, and at the same time avoids dry heat that might rise to pans of seedlings placed on the back stage if the pipes passed under it. At one end of the front stage a portion should be partitioned off, with a glazed frame cover on hinges. Under this frame many seeds will germinate more satisfactorily than on the open stage, and with a variety of accommodation thus provided the seedling-house will be capable of ensuring the best results from practically all classes of seeds.

Underneath the stage racks may be placed, upon which trays of stratified seeds of trees and shrubs may be placed. It is of material benefit to stratify hard seeds, berries of shrubs, etc., in trays of coconut fibre before they are actually sown in soil.

Sometimes raisers of ferns, orchids and tender succulents find it advantageous to make use of a porous bed of burnt earth, stone chippings or washed sand, somewhat after the style of the moraine of the rock garden. Such a bed can easily be made on the perforated malt-kiln tiles, the under-current of moisture being secured by sinking a few small empty plant pots in the bed and filling these with water as required.

One further detail requires to be mentioned—the water tank should be so fixed that the hot-water pipes come in contact with it for the purpose of warming the water, and it should also be so situated that seed pans may conveniently be dipped, that being a method of watering seedlings which is well known to be infinitely better than overhead watering.

The differences between the house I have described and an ordinary house may appear trivial and insignificant, but it must be remembered that most seeds are small, many are minute, and seedlings are the babies of the plant world, consequently small matters are of great moment. If a seedling-house is to be built it is well worth while to attach to it a seed store. Quite a small extension will accommodate many seeds, but the store should not have a glass roof, a window to admit light being all the glass desirable. Metal despatch-cases are the best cupboards for seeds, and glass jars or bottles for the seeds are better than paper packets or cardboard boxes. Bins for soil, sand, charcoal, etc., may be accommodated in the store, or potting-shed.

A. J. MACSELF.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

NOTES FROM CONTRIBUTORS

SCABIOSA CAUCASICA.

DURING the last few years a wonderful advance has been made with this beautiful scabious, and now there is a number of distinct varieties which make it necessary in numerous gardens to devote a bed or border to their cultivation. When we consider their long flowering season, their lasting qualities and decorative value as cut flowers, it is surprising that they are not more widely grown. The plants are true perennials and quite hardy, but slugs are very fond of all varieties of S. caucasica. These marauders will soon destroy the strongest plants, and herein lies the cause of most failures. To be successful slugs must be kept down, and the only effectual remedy I have found is lime. The usual mere dusting is useless, a handful of dry dust lime must be placed on each plant, and Mr. House of Bristol tells me he has often done the same thing with excellent results. Lime is given during the winter months, and it is at this season that slugs are most destructive.

S. caucasica may be planted from March to September, choosing a well drained position away from the shade of trees and other plants. No doubt it is best to grow them in a separate bed or border, but if the herbaceous border is chosen, then an open clear spot must be given. Every third year the plants are divided, and such work should be done in March or April. When well grown, and if slugs are kept in check, there is no difficulty in this direction. No staking is needed, the growth being erect, and the flower-stems are strong, a fact which makes them so valuable both for the garden show purposes and dwelling-house decoration. In addition to the type of S. caucasica, which is a beautiful shade of pale blue, there is a white form known as alba and another as White Queen. Two very fine dark varieties are named Isaac House and Diamond, but now there are others in various shades of mauve and blue. An interesting task is raising them from seeds, and these should be sown in March or April in pots or pans of light soil. They will germinate in a frame or greenhouse, and directly the seedlings are large enough transfer them to their flowering positions. The majority will be inferior to already existing varieties, but there is the possibility of flowering something really good, while many will be of garden value.—T. W. B.

"WHAT S IN A NAME?"

I HAVE been occupied recently in my annual task of making out the order for the kitchen garden seeds. As I read the long roll of magnificent names which adorned the seedsmen's catalogues, my thoughts wandered in contemplation of the influence exercised by names on human minds and actions.

Do not travellers tell us of Eastern races who, through fear of the malignity of evil spirits, call their infants by repulsive names, in the belief that the menacing powers will not trouble to pursue with their vindictive hatred babies bearing names such as Son-of-a-Rat, Bit-of-Dirt, Moth-eaten-Rubbish, and others equally unpleasant? This custom is, of course, merely an example of belief in the repellent force of names, and need not occupy our consideration now.

As Westerners, we are more influenced by their attractive and awe-compelling force, as shown in the choice of the remarkable names bestowed on garden flowers, bacilli, patent foods and remedies, racehorses, dress materials, diseases, semi-detached villas and many other things. None of these, however, rivals the super-nomenclature which make seed catalogues so bewilderingly dazzling. During the course of fifty years, the nursery gardener has succeeded in raising his placid vegetables to such a pinnacle of glory as cannot fail to excite the envy of every other owner of a proud name.

Who can attempt to vie successfully with "Peerless-Perfection," or "The Wonder-of-England," or "Ne-Plus-Ultra," or "Marvel-of-the-Season," or "Best-of-All," or "Nonpareil," and so on? And these names are not only superlative in themselves, but, like gilded gold and painted lilies, they are emblazoned with descriptions matching them in splendour: "Royally magnificent," "Very prolific and reliable," "Superb and very hardy," and "combines every desirable qualification, having carried off in open competition many costly awards," etc.

May we hope that the time may not be far distant when the knowledge that humble vegetables have reached these heights of perfection shall spur on other ranks in the scale of creation to attempt the attainment of even greater success? We may expect that the impulse will extend to human beings, possibly even to politicians. When this happens, we shall really see the beginning of the New Era, which, despite all the prophecies of statesmen and dreamers, has not yet dawned on us.

As nothing on earth is absolutely flawless, we cannot expect that time of bliss to escape all imperfection; and recent experiences suggest to my mind that one of them may be felt in a probable increase of complexity in voting at a parliamentary election. It is very difficult under our present circumstances to be always certain of selecting the right candidate; but in those days, when men and women will win a super-nomenclature for themselves, who will be able to decide between the rival claims of candidates, whose attributes are displayed after the manner of the seed catalogue! Imagine a four-square contest, where our suffrages will be asked by:

1. CHAMPION GIANT. (Major George Marne.) *Conservative.* "Large, solid and handsome. Superb strain."
2. TITAN. (Mr. D. Mocrat.) *Labour.* "A perfect type. Extremely vigorous. Full of promise of unique prolific fruit bearing."
3. NONSUCH. (Sir Bentham Mill.) *Liberal.* "Very solid head. Wonderfully robust. Disease-resisting."
4. TENDER AND TRUE. (Mrs. Eve.) *Independent.* "Excellent and very beautiful. All heart. Delicious."

I am thankful that I am not called to make my choice between these names. It is hard enough to resist name-influence in selecting my onions and peas. My hand trembles as I now reject "Royal Favourite" and order one packet of "Champion of England" instead.

And Shakespeare asked: "What's in a name?" But it must be remembered, as his excuse, that he put his foolish question into the mouth of an extremely young person. —(Lady) LAURA RIDDING, *Hants.*

CALYPSO BOREALIS.

ONE is sometimes disposed to envy the happy man who can grow orchids and, perhaps, unduly admire the products of his greenhouse. Everyone, however, who owns a piece of ground or a flower pot and some suitable soil, may gratify his ambition to grow some of these choice flowers and if the available species lack size and showiness when compared with the products of the glasshouse, they yield nothing in sheer beauty. As an example of the truth of this, take Calypso borealis, a native of Northern Europe and America and therefore a perfectly hardy plant in this country. It is conspicuous from the fact that it produces but a single broad leaf, very thin in texture. From the axil of this in summer, a slender sheathed stem pushes out bearing a solitary flower, something like a cypripedium in shape and of an exquisite rose colour.

Can such a gem be grown in the open air? you ask. Certainly it can and, although special soil and cultivation in some directions are necessary, it is not more difficult than a geranium or any other average plant. Where grown in the open ground, a half shaded site should be chosen, preferably in the rock garden or on the margin of a bog, for, in such spots as this, it is far less liable to be disturbed than where grown among a varied collection of plants. Its chief requirements, in the way of soil, are a light rich mould in which constituents of a vegetable nature predominate. An annual top dressing of well decayed oak leaf-mould or coconut fibre is especially valuable each spring, for this not only feeds, but also assists in retaining moisture and, more important still, in keeping the roots cool. In pots, drainage should be the first thought, for, while it loves moisture, it detests stagnant wet and quickly perishes when continually exposed to this. Pot moderately firmly and stand in a similar half-shaded position, taking care that the pot itself is well screened during summer and does not become hot. In place of the annual top dressing, advised for plants grown in the open ground, a portion of the surface soil should be annually picked away in early spring and replaced by a layer of fresh compost of a similar nature to that in which the plants were potted. See to it that the soil never becomes dry at any time, but exercise special care in this direction during summer, while the leaf and flower stem are in active growth.—HAVELOCK.

RHODODENDRON NOBLEANUM.

IT is more than seventy years since Messrs. Standish and Noble of the Sunningdale Nurseries crossed the blood-red Rhododendron arboreum with R. caucasicum, producing thereby the fine hybrid known as R. Nobleanum. We do not make nearly enough use of it. Except in the grounds of those who have contracted the modern disease rhododendronitis, it is only here and there that one's eyes are gladdened with its midwinter glow. Yet it is as hardy as the universal R. ponticum, a quality inherited from its Caucasian parent, and may be grown successfully in any part of Great Britain where the soil is free from lime. In a mild winter such as the present has been so far (I write on Christmas Day), R. Nobleanum is simply priceless, lighting up the gloom of the winter solstice with a profusion of crimson bloom. It is true that the display may be quenched by a single night's frost; but it is a notable feature in this shrub that it always has a number of flower buds in reserve to replace the blossom destroyed so soon as the calamity is overpast.

Noble's original cross has been repeated several times, sometimes probably reversed, with the result that there are several forms of R. Nobleanum in cultivation, none of them, so far as I have seen, equal in stature or richness of colour to the first, which is now, unfortunately, difficult to obtain.

The present season has been ideal for this rhododendron. Owing to the cold, wet summer, the bushes opened no flowers in October as they usually do here, thereby escaping 5° of frost which we had early in November. Since then they have increased steadily in glow, and will carry on so long as the weather remains open. This hybrid is pretty generally grown in pots for conservatories, which they furnish very prettily; but the flowers under glass never equal the rich hue of those borne in the open.—HERBERT MAXWELL, *Monreith.*

CORRESPONDENCE

NERINE MRS. W. R. LYSAGHT.

SIR,—I quite agree with the remarks made by Mr. F. H. Chapman in your issue of December 13th, 1924, regarding nerines, and it has always been a puzzle to me why they are not more largely grown. In these days there is a wonderful variety, and when in Cornwall some two or three months ago I saw some extra fine nerines, almost a glowing scarlet when the sun was shining on them. The plants of N. Mrs. W. R. Lysaght illustrated in THE GARDEN for November 15th last were identical, and from the same cross. Like Mr. Chapman, I have raised many seedlings, and it is the first time that I have noticed such a striking similarity in the progeny, although some seedlings were very much alike. These, however, were as a rule of no great merit, and were generally consigned to the rubbish heap. One of the most interesting jobs in gardening is the raising of seedlings, especially when one has chosen the parents and duly mated the twain.—T. W. BRISCOE, *Chepstow*.

HIPPOPHÆ RHAMNOIDES IN WINTER.

SIR,—Nearly every gardening paper at this season of the year speaks of the advantage of coloured stemmed shrubs, and your correspondent (December 27, 1924, page 862), gives the names of a great many desirable shrubs. Why is it that one so seldom sees the beauty of Hippophæ Rhamnoides mentioned in this connection? Its stems are a rich shade of brown with an attractive grey bloom over them. The bold growth has much more artistic character than most other coloured-stemmed shrubs, with the added interest of long spines and plump golden brown buds along the branches. The male plant is the most attractive in winter, but the female carries bright berries in the autumn.—GWENDOLYN ANLEY, *Woking*.

FASCIATED FLOWERS OF IRIS STYLOSA.

SIR,—I enclose a photograph of a plant of Iris stylosa having the flower perfectly fasciated. The plant is in a very warm situation in the corner of a south border against a wall, the soil being largely sand. All the flowers produced are fasciated like the one shown, and at the moment of writing there are three flowers in bloom. The foliage is shorter and narrower than usual, and the flower-stems are stout and short. All the parts of the flowers are duplicated.—I. R. L. WILSON, *Charterhouse, Godalming*.

A PLANT OF IRIS STYLOSA WITH FASCIATED FLOWERS.

SNAILS AND SLUGS.

SIR,—In THE GARDEN of December 27th, 1924, I see it is stated in a note, in reply to a query by a correspondent regarding slugs, that "there is no chemical preparation that can be used to destroy the slugs without injury to the plants." It does not seem to be generally known that powdered alum will effect the destruction, without the least injury to the plants, of both snails and slugs, and that once they come into contact with it there is no chance of their escaping, except to die. They cannot slough it off, as they can do salt and soot. And a strong solution made by dissolving a lump of the material in boiling water and applying it as hot as possible, so that the steam may find its way into the crevices and air spaces, is invaluable for exterminating them from refuse heaps and other harbours where they hibernate and breed. Both adults and eggs are effectively destroyed by this means.—A. D. RICHARDSON, *Edinburgh*.

CINERARIAS WITH STRIPED FLOWERS

SIR,—I have been watching with much curiosity the development of the flowers of a star type of cineraria which has flowers of a pale mauve colour striped with dark blue, as I have never seen this freak (if it may be termed so) in either of the stellata or star type before, and I am curious to know if any reader of THE GARDEN has met with any like experience.—HENRY SQUELCH, *Chislehurst*.

EPIPHYLLUM COCCINEUM AS A WINDOW PLANT.

SIR,—Until living in this country I had never seen the above plant kept in a cottage window; but that it can be so grown and flowered I have, on more than one occasion, had ample proof. True, the seen specimens were on the small side, but this would be due, mainly, to the plants being rooted on their own roots and not grafted, as most of the plants are that one meets with in big gardens. Of course, own root plants attain a good size in time, but it takes longer to obtain large plants this way than it does when they are grafted on a stronger-growing cactus—to which family this plant belongs, the epiphyllum being a sub-genera of this extensive genus. Quite recently, the end of November, I had an illustration of the slow-growing nature of this plant from the cutting stage. The plant was in the possession of a railway worker, who had a piece of growth (or a slip, as he termed it) given him on the occasion of his wedding twenty years ago—the plant being now in a 5in. pot, about 15ins. high and 10ins. or so across. This specimen was housed in an outhouse adjoining his cottage, the only warmth supplied coming from the chimney of the living-room against the end of which the outhouse was built. The foregoing evidence goes to show that the epiphyllum will stand tremendous extremes of warmth and cold—for in its growing season it appears to revel in a stove temperature, and yet it will withstand the naturally variable temperatures of such places as mentioned. And what is more, these plants flower—thus proving the epiphyllum to be an excellent plant for the cottage window or the drawing-room, being not too fastidious in its requirements and attention.—C. TURNER.

LILIUM AURATUM.

SIR,—From time to time I have seen illustrations in THE GARDEN of Lilium auratum. I thought perhaps that the enclosed snapshot

LILIUM AURATUM IN VICTORIA, B.C.

of this lily growing in my garden in Victoria, British Columbia, might be of interest.—JOHN HUTCHINSON, *Victoria*.

FLOWERS BLOOMING IN THE OPEN AT CHRISTMAS.

SIR,—The enclosed list of over two hundred distinct species of flowers found in bloom during Christmas week may be of some interest. They are all growing in West Porlock, either in Mr. G. W. W. Blathwayt's garden or in mine, and none has received any artificial protection.—N. G. HADDEN.

FORCING POTATOES IN GREENHOUSE & FRAME

ONE rather wonders why potatoes are not more frequently forced by those who have the accommodation. My own experience is that if you make up your mind to grow anything, and start it, you will find room for it somehow. Where a frame can be provided the question of room is not likely to be so difficult. For early forcing the method of forcing in pots will be preferred, the successional crops being grown in frames.

Eight or nine inch pots are best suited for the purpose, and there should be no difficulty in obtaining these now that many of the chrysanthemums are getting over. These pots should be thoroughly dried and may then be brushed clean with a stiff brush. I know that I shall be considered a heretic in not advising that they be washed, but for a purpose like this I consider it a waste of time, and it would certainly not make the slightest difference in the crop. That presumes, of course, that they are not unduly dirty. I do, however, insist that the pots be perfectly dry. At this time of the year that will mean drying them over the hot-water pipes or the boiler. The pots will, of course, again be available for chrysanthemums after the potatoes are used.

No elaborate drainage will be needed—merely one large crock and a covering of leaves. Rather more than a double-handful of soil will be sufficient to put below the tubers, else there will not be much room for top-dressing. The tubers are just placed on the soil without any attempt to press them in, and sufficient soil is added completely to cover the tubers by about an inch. Care must be taken not to injure the growths, if any. In this way the pots will be little more than half full, the remaining space being left for top-dressing.

In point of earliness I doubt whether there is any advantage in getting the tubers to sprout prior to planting, but there would be the opportunity of limiting the number of growths, and to some extent the advantage, in the matter of space, in not having to pot the potatoes quite so soon.

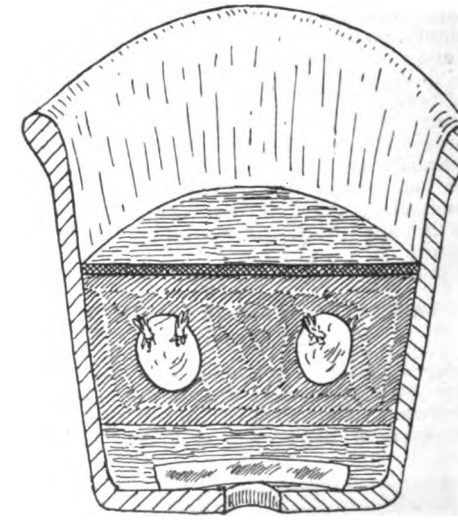
In the ordinary garden there should be no difficulty about soil because the soil which has been used for chrysanthemums will do well for the purpose. The roots should be shaken free from soil and this should be passed through a ½in. sieve, and then freshened up by the addition of some leaf-soil and sand. The addition, also, of some manure from an old mushroom bed will be an advantage.

Here I may mention a neat little method of catch-cropping which I have practised

with success. When the potatoes have been potted and watered, a thin layer of very fine soil or leaf-soil is sifted over the surface. On this is sown either mustard or cress (usually a few pots of each). If the pots are placed in a warm house this may be cut before the potato growths appear above the surface.

The potatoes must not be grown in a very warm house, else the growths will be weak and there will be less prospect of a good crop of tubers. As soon as the growths appear above the surface an abundance of light should be given, and a position fairly near to the glass. Top-dressing and staking may be done at one operation. With the soil for this purpose may be added some mushroom manure and some good fertiliser, such as Peruvian guano, a good watering being given afterwards to settle the soil. When the roots have laid hold of this soil, watering with liquid manure may be freely given in weak doses.

Support may be given to the growths by setting some birch or hazel boughs around the plants. Another method is to put four sticks in the pots and to encircle these with raffia. I might here mention that when the potatoes are grown in frames there will be no need to give any support. When growth is pretty well completed the pots may be put into a cold frame to be used as required. A little hardening will be necessary when



this practice is adopted. The advantage of using pots instead of frames is that the pots may be moved about, and valuable space is not taken up from beginning to end of their career, as would be the case in a warm pit or fixed frame.

Potatoes may be forced in a heated pit or in a frame standing over a hot-bed. In either case the cultivation is practically the same. A depth of 10–12ins. of fairly good soil will be necessary. The distances recommended are 8ins. between the tubers and 15ins. between the rows. A little soil may be added by way of top-dressing, but this is neither usual nor necessary. The depth of the frame should be so arranged that the growths are not far from the glass, nor yet sufficiently near for them to touch the glass, which would endanger their being injured by frost. Covering of the lights will be necessary on cold and frosty nights. Radishes or carrots may be sown between the rows if desired. Obviously only dwarf and early varieties are suitable for forcing. W. F. ROWLES.

SIMPLE GARDENING

COMPOSTS FOR SEEDLINGS AND SEEDS.

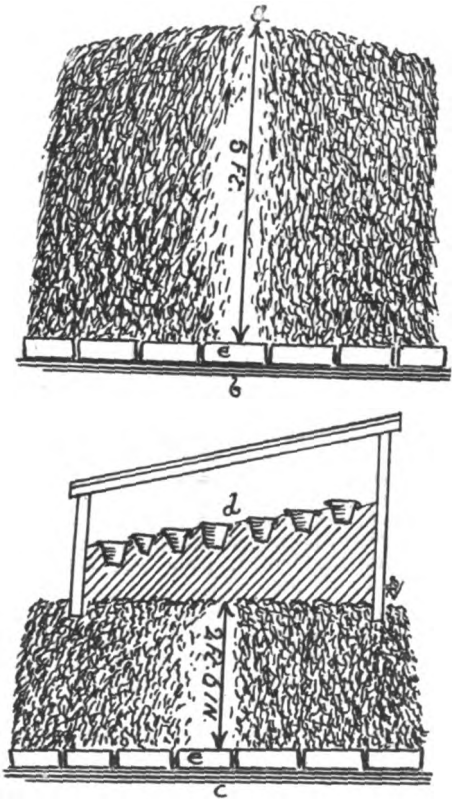
IN the pots, pans and boxes in our greenhouses there are thousands of tiny seedlings of tender and half-hardy plants. All these seedlings—or the best of them—must, in due course, be shifted to small pots, then to larger pots or into boxes and, perhaps, from the latter into frames or sheltered borders. In every case it is necessary to prepare a special mixture of soil, and for the benefit of those seedlings essentially belonging to the greenhouse great care is needed in selecting the ingredients. Some seeds are not larger than tiny grains or particles of dust and should not be covered at all when they are sown. I name only two kinds, tuberous begonias and gloxinias. These and similar ones are best sown in soil in pots or pans. The seed vessels are washed and dried, crocked with clean potsherds and three-parts filled with a compost of light loam, leaf-soil and sand, all passed through a fine-meshed sieve. The surface is made level and the soil watered; when partly dry the seeds are sown as thinly as possible, and the pan covered with glass and brown paper. The even moisture causes germination. For larger seeds, such as those of primulas a rather coarser compost of the same ingredients will answer. The seeds must be lightly covered, and very similar treatment is right in regard to numerous seeds of annuals, the resultant plants of which may be flowered in the greenhouse or the garden. For larger seeds and strong-growing plants, loam two parts, leaf-soil one part, old mortar rubble or sand one part, will do as a compost in still coarser condition.

EARLY FRENCH BEANS.

Of course, I must say, first of all, how difficult it is to grow these satisfactorily early in the year unless artificial heat is adequate. If the day temperature of the house or forcing pit cannot be maintained at summer heat, do not attempt to grow these beans under glass at all. The low, well heated pit, preferably a lean-to facing due south, is an ideal structure for the purpose. Osborn's Forcing, Ne Plus Ultra and Williams' Earliest of All are suitable varieties. The crops should be grown in flower pots, those 6½in., 7in. and 8in. in diameter are the best, using them in the order above for earliest, second early and latest batches of plants. They should be washed clean and thoroughly dried, the crocks also. Ample drainage is essential as water is needed by the plants very frequently when the soil is full of roots. Over-dryness of the soil causes the flowers to drop off prematurely and encourages red spider on the leaves. No flowering plants should be placed in the same house as the beans on account of the frequent syringings necessary and the regular atmospheric moisture coupled with the closeness generally—because no ventilation should be given. The best compost is one of good fibrous loam, cut and stacked quite six months, two-thirds; and rotted manure, one-third. The pots should be three-parts filled, three seeds in each pressed into the soil 1in. deep.

HOT-BEDS.

These have a fascination for all who love their gardens and wish to make them both interesting and beautiful. The hot-bed, properly made and managed will be very useful in the raising of seedlings and the rooting of cuttings. There is always a nice heat and some moisture surrounding the seedlings and cuttings, and it is the warmth, coupled with the moisture, that promotes root action. In cooler conditions the cuttings would take a long time to strike root, and many would die; seeds without heat would



be slow to germinate, many would rot in the soil. But the hot-bed is dangerous to plant life, too, if it is not properly managed. The heat may be too high or the atmosphere too damp. The first is regulated to a great extent if the bed is well built and the materials composing it thoroughly prepared. The second is regulated mainly by judicious ventilation of the frame placed on the heap. Strawy manure, two-thirds, freshly fallen tree leaves, one-third, well mixed, will form a bed in which the heat will remain steady for several weeks. The littery manure must be spread out thinly in a cool shed and turned over several times for a week or so to get rid of the rank gases. The base should be a dry one and the bed *a* should be evenly built up to a height of 5ft. The section is shown at *b*. In due time the bed will settle down to 2ft. 6ins. as shown at *c*. The letter *d* shows how pots or boxes may be plunged in the soil on the bed, or crops may be grown in the soil. The loose basal bricks are shown at *e e*.

HOLLYHOCKS FROM SEEDS.

When the hollyhock disease practically killed the stocks of plants in this country a great effort was made by our florists to supply seeds instead of plants. This effort met with great success, almost at once, especially as regards the single-flowered section. Then followed more fixity in the double-flowered one, and to-day, every cultivator may soon raise a big batch of plants of either, or both, sections and obtain a large percentage of double or single flowers true to form and colour with a few exceptions. A normal hollyhock plant attains a height of 7ft. 6ins. in one season, so we can at once realise the fact that growth must be rapid at some stage. As even the seedlings possess large leaves they must have ample room to grow in, so the seeds should be sown 1in. apart. I find pans better than boxes for the seedlings; drain the clean pans well, use a compost of mellow loam and sweet leaf-soil in equal proportions. Cover the seeds half an inch deep after sowing them on watered soil; place the pans on a stage till the seedlings appear, then lift the pans to a shelf nearer the roof glass. Transplant the seedlings quite close to the rims of other pans; at the next stage singly into small pots, then a re-potting into 6in. pots and cold frame treatment prior to final planting.

FUCHSIAS FOR GREENHOUSE AND GARDEN.

Thirty years ago the fuchsia was regarded as one of our principal greenhouse plants for summer flowering. Later it was used freely for bedding-out associated with other kinds of plants, all combining to form a bed group equal in beauty to the groups found in our conservatories. The fuchsia is very popular in these days; it can be rested during the winter months and stored in sheds without the expense of artificial heat. Plants so treated should be placed in the greenhouse very soon now. One application of water to the soil will be sufficient for ten days, but every morning the branches should be syringed with water of the same temperature as that of the house. In the course of a fortnight new shoots will grow and it will be clearly seen how far back some of the ends of the shoots have dried; these dead tips of shoots should be cut off. When the young branches are about 1in. long, the plants should be carefully turned out of the pots and the old ball of soil much reduced to allow of re-potting into smaller pots. It may be necessary to cut off a few of the old roots, too. A very suitable compost for all fuchsias is made of the following ingredients: fibrous loam, two parts; leaf soil, one part; old bricks pounded almost to dust and old lime rubble, one part. To every bushel add a single handful of bonemeal and a 5in. potful of wood ashes.

SEED POTATOES

THERE is a distinct danger in the constantly recurring advice to prefer small tubers when selecting seed potatoes, and growers ought to know wherein the danger lies. Before pointing it out, however, the admission must be made that small immature tubers from a clean crop are undoubtedly best—emphasis being laid on the words "immature" and "clean."

Potatoes are subject to many diseases, many more, indeed, than gardeners realise; many of these diseases are not properly understood and of some there is no definite information at all. One point about many of these is that they result in more or less stunted growth and the consequent small crop, small in total weight, but more particularly small as regards the size of individual tubers. It is very often the tubers which carry these diseases, and so, by selecting small tubers, the grower is taking strong steps to secure a crop infested with the same disease. a small and disappointing crop.

Again, potatoes revert or, as the specialists know, they produce odd plants which have distinctly wild or primitive characteristics and are not true to variety. Invariably the tubers at the root of such a plant are small, hence another danger—that many plants are worthless "wildings."

Lastly, small potatoes may be the weaklings of mature and well ripened plants. No one will argue that the best result can be obtained by using as seed tubers which are the worst of a previous crop. Many good old varieties have passed out of favour, and maybe out of ken altogether, by continuous selection of small tubers for seed. The remedy—for there is one—is not far to seek. If small tubers will be used, then they must come to the gardener or farmer with a guarantee that they are the produce of a clean crop (the word clean is difficult to define, but I think readers will see what I mean). Moreover, they should preferably be immature, *i.e.*, from a crop that was checked by being lifted or frosted before it had time to reach its full development. Potatoes from the North are often best in this respect.

But there is another and better remedy, and that is to use large tubers as seed instead of small. If the grower looks over a pile of potatoes he will soon see the best—not the largest, but the best in shape, size and appearance. These will sprout easily and at planting-time may be cut into two or even three. If the flesh is clean when cut, then the chances are that the tubers are really sound, the best. This is an old plan with potatoes, remember, but it is still a good plan, and we cannot do better than repeat our first phrase, there is a danger in small tubers. CLYDESDALE.

COB NUTS

COB nuts are enjoyed by everyone, and it is a wonder that more attention is not given to their cultivation, especially as a crop will sometimes yield as much as £50 per acre, while this class of produce has an advantage over ordinary fruit in its keeping qualities. Many orchard products, on account of their perishable nature, have to be marketed at once, and often for what they will fetch. This is not the case with cobs, and the grower is, consequently, not handicapped. His crop, with ordinary care, will keep for months after being gathered, and the nuts are not liable to get bruised in packing and travelling. Nuts, of course, are in great demand during the festivities of the Christmas season, and a rise in price may be looked for as it approaches, especially if there has been a short crop.

The trees should be planted in a somewhat sheltered position, as they suffer from the effects of wind, and should be about 12ft. apart each way. The space between may be profitably utilised before the trees come into bearing by planting small fruits underneath, such as gooseberries, currants and strawberries. A row of standard plums, damsons or apples may also be put in. The fruit bushes must be removed when the nuts attain their full size.

The training of the young nut trees is important. A start should be made with a good clean stem 18ins. to 2ft. in length, and the pruning continued season after season, so that the tree ultimately assumes an open bowl-like shape. The branches should be evenly balanced all round — about half-a-dozen of them radiating from the central stem; in fact, in a well trained tree a gigantic basin could be dropped into the centre, and the branches of the tree would support it on every side. There must be no branches running crosswise, and each year all suckers and wands should be removed as soon as they appear. From this brief description it will be seen that the pruning of nut trees is radically different from other kinds of tree pruning.

The nuts generally planted are the Kentish Cob, a bold thick-shelled nut. This cob is very prolific, bearing nearly double the crop borne by other kinds. The Cosford is a rounder nut and a good bearer, but the shell is very thin and liable to be selected by mice and squirrels. Webb's Prize Cob is larger than the Kent Cob, and the nut makes a better sample for market. The Red Filbert (Merveille de Bolwyller), a very large cob, is useful for gardens.

Oswestry. R. E. DAVIES.

CATALOGUES RECEIVED.

A fine catalogue has reached this office from Messrs. Alexander and Brown at Perth. Perthshire is a noted gardening county, and it should be proud to have a seed house of such distinction in its neighbourhood, for the seeds listed in this catalogue are of noted quality. We should also like to draw attention to the excellent production of the catalogue, one of the best that we have seen. It is printed by a local house, and both the text and the blocks, plain and coloured, are excellently produced.

Another catalogue from a well known firm in the North is that of "Stronghold" seeds produced by Stewart and Co., 13, South St. Andrew Street, Edinburgh. The list is particularly strong in standard varieties.

Messrs. Dobbie's name is known from Land's End to John o' Groats in connection with all horticultural matters and more especially to those interested in the growing of potatoes. Throughout the past year this firm has maintained, if not surpassed, that excellence which has always characterised its productions of vegetables. It is with pleasure that we bring the notice of the New Spring Catalogue to our readers. It is a handy manual running into 136 pages and is copiously illustrated by means of numerous half-tone reproductions. Half is devoted to vegetables, while the other half is given over to flower seeds, with a separate section on liliums, gladioli and sweet peas, the latter being a strong speciality of this firm and one through which its name has come to the front rank of horticultural firms. It is a catalogue which all our Scottish readers should have.

When contemplating to which firm the year's vegetable list shall be sent the name of Webbs' comes to the mind of the majority of gardeners. For years this firm has retained its reputation for producing flower, fruit and vegetable seeds of excellent quality. The vitality and germinating powers of the seed are known to be of a very high standard and above the minimum percentage prescribed by the Seeds Regulation. The seed catalogue which Messrs. E. Webb and Sons, Stourbridge, have just published is another testimony that they are worthy of a place among the leading seedsmen. Carefully compiled, well illustrated and giving brief but good cultural notes, this catalogue will be most useful throughout the year. Not only does it give long descriptive lists of many varieties of each vegetable and flower, but it offers for sale bulbs for spring planting, and various horticultural requisites.

Expensively produced catalogues do not necessarily signify that the articles described therein are of a similar standard. Although others may be somewhat less luxurious in appearance, the goods advertised may yet be of an excellent quality. This applies to the seed catalogue of the long-established firm of Dicksons of Chester. It contains a wealth of information about flowers and vegetables of which Messrs. Dickson can supply the seed. Mushroom growers would be well advised to try Dickson's improved mushroom spawn, and those who are not practised in the art of growing this delicious crop will find very helpful cultural details in Messrs. Dickson's catalogue.

And yet another catalogue which is well worth studying is that of Messrs. Dickson, Brown and Taits of Manchester, which contains first-class seed lists of vegetables and flowers, and advertises horticultural sundries and various oddments which are not advertised in other catalogues. All kinds of potting material, fungicides, insecticides, orchid fibre, etc., are included. The flower portion of the catalogue is particularly well illustrated with a considerable number of half-tone flower portraits which give an excellent idea of the good strains sent out by this firm.

PUBLICATION RECEIVED.

"Webster's Foresters' Diary for 1925."—This is the twenty-third year of the publication of this excellent diary published by the *Timber Trades Journal*, 8–11, Paternoster Row, E.C.4, at 3s. 6d. net. It contains a great deal of useful information for all who work among trees or are interested in them. Particularly good are the tables for identification and remedial measures in the case of insect pests and fungi. The diary is of handy size and is bound in imitation leather.

New Carnations.—The British Carnation Society has recently registered the following new varieties of carnations:

Gwladys Berry, pedigree seedling, crimson clove, fair fragrance, habit short and bushy, especially suitable for bedding. Stuart Low and Co., Bush Hill Park.

Lady Hindlip, pedigree seedling, white striped red, sweet fragrance, sturdy and free-flowering. Stuart Low and Co., Bush Hill Park.

Viscountess Hambleden, seedling, Benora × Aviator, rich apricot red, striped and flushed with red, distinct fragrance, stiff stem and free grower. Mr. W. Turner, Greenlands, Henley-on-Thames.

Marchioness of Salisbury, seedling, Enchantress Supreme × Britannia, superb pink, good fragrance, long stiff stems, vigorous grower. Mr. R. H. Hall, gardener to Marquis of Salisbury, Hatfield, Herts.

Dainty, seedling, orange ground, speckled salmon pink. Mr. C. Engelmann, Saffron Walden.

Janet, seedling, cerise, fair fragrance, good stem, dwarf grower. Mr. C. Engelmann, Saffron Walden.

Name of Plant. — (Regular Reader).— Saintpaulia ionantha.

THE LIMITATIONS OF PLANTS

DR. PRAEGER contributed to the last issue of THE GARDEN a frank article on "Plants I Have Killed."

It is only natural that botanists, who at the same time are experienced cultivators—by no means such a common combination as might be expected—in the course of their experience with plants must have a certain percentage of casualties; in fact, the surprising thing, considering the miffiness of some plants, is that the percentage of casualties is so small. If, as I say, experienced cultivators have casualties in their gardens, it is obvious that the percentage of deaths in ordinary gardens increases in an inverse ratio according to the lack of skill, or of insight, of the cultivator, if the proverbial luck of the beginner is not taken into consideration.

From the point of view of this article, plants may be divided into two broad groups, those which are thoroughly established in cultivation and those which are not. In the first group casualties are caused through human agency; that is, that experience has taught us what the particular plant requires for its successful growth and ultimate arrival at maturity. The plant is intimately understood by numbers of individuals; its necessities and economics are described in books and in the horticultural press; therefore casualties above the average are largely owing to the human factor in its cultivation. It may die owing to wrong treatment in a young state, or to being planted in a wrong medium or under unsuitable climatic conditions. It may succumb owing to a hundred and one different causes, each of which is due to the lack of experience of the grower. All these causes are avoidable because the plant's successful cultivation is known and recognised by a large body of gardeners.

This experience is only gained after a number of years. In many cases it is only known from the combined efforts and experiments of generations of gardeners. Now take the case of the second group. Certain plants, even after years of trial in various parts of the country, have not proved themselves amenable to cultivation in gardens. In many cases the ordinary terms of success or failure, such as hardiness, susceptibility to insect pests, drought-resisting and so on, go by the board. There may be no conceivable reason why the plant should not grow, and yet it won't; it is stubborn, for its interior balance is upset. It is analogous to placing a shepherd in a city office or *vice versa*. There is no doubt that some plants are placid and adaptable, while others are so highly strung that the slightest change of environment and mode of life is fatal.

As this change of environment and mode of life is so important to a plant, it is as well to find out all there is to be known, which may not be much, about an uncommon plant. Because you see it flourishing in a friend's garden is no insurance that it will succeed in yours. Probably it will; possibly it may not. Here are a few of the main points to look out for:

1. Soil conditions. Are they the same as that in which the plant flourishes? If not, can you approximate them by additions?
2. Light and shade. Do you know how much sunlight the plant requires?
3. Protection. Was it sheltered from the wind? If so, which wind?
4. Water and moisture. This follows on point one. Does your soil retain too much or too little moisture? Is winter drought or winter wet a necessity?
5. Space. Do you know its mature size, and are you allowing for this?
6. Associations. Is it a plant which likes companionship? Does it like to grow in groups or is it solitary?
7. Feeding. Does it require feeding, and if so, what food?
8. Hardiness. Is it hardy or not? This word "hardiness" is constantly misused, for hardiness is a question of degree. Many casualties are put down to a plant not being hardy when the cause of death may be errors in any one of the above seven points. For instance, many plants are useless around London, because they are cut with the spring frosts and yet farther north they may flourish exceedingly, because they start into growth later. These plants are called soft, which is technically untrue. Their balance is upset.

I should also point out that there is a converse to this argument. Supposing a plant will grow in A condition of soil with B amount of moisture and C hours of sunlight, and so on. That may constitute a happy mean of its limitations, and so latitude may be allowed on either side. On the other hand it may prove to be the extreme at one end of the scale or the other, and so, though you can add more hours of sunlight, you cannot grow it in deeper shade. Yet a bird in the hand is worth two in the bush, and if you know, or can find out under what definite conditions a plant will grow, try to equal them and so keep down casualties, which are unavoidable in experiments.

Remember that every plant has a statute of limitations and if you go beyond it, the balance is upset and the plant dies. Some gardeners have second sight about a plant's requirements; they are the lucky ones. Others, who like experimenting with unknown plants, see their casualty lists creeping up.

THE CULT OF THE POLYANTHUS

THERE ARE FEW SPRING FLOWERS WHICH PROVIDE SUCH AN EXCELLENT DISPLAY AND CAN BE PUT TO SUCH AN INFINITE VARIETY OF USES AS THESE MANY FLOWERED PRIMROSES.

IT is doubtful if there is a more generally useful long-blooming spring flower than the old-fashioned polyanthus, and on the score of beauty too it can certainly claim a very high place. Good as the old plant of our childhood's days appeared, it must be admitted that the modern strains are infinitely superior in every way. Cleanness of colour, size of flower, strength of the trusses and the manner in which they are held high above the rosette of leaves—in all these points the improved strains score enormously.

That, of course, is all on the side of garden display and does not apply to some of the interesting old-fashioned forms that are still as good as ever, from the point of view of those who are keen on unusual or old-time flowers. It would be a pity, for instance, to miss Jack-in-the-green, a crimson form surrounded by a foliaceous calyx, known botanically as Primula officinalis macrocalyx. Are there not, too, the queer hose-in-hose forms, in white, scarlet, crimson and gold, and deep yellow ?

THE POLYANTHUS ENJOYS THE SHADE OF THE WOODLAND.

These have smaller flowers, but are very curious, having a flower within a flower and both similarly coloured. Nor must we forget the gold and silver laced forms, which—though again small—are in the richest possible colouring. In some cases the flower is crimson, in others so deep a brown as to appear practically black ; while in every case each bloom is edged by a narrow but very distinct gold or silver line.

Of modern bedding strains, those who appreciate light colours—and it must be recognised that these carry well—it would be very difficult to beat the Munstead strain. In this the flowers are of enormous size and splendidly clear colouring, with well defined eye and ranging from pure white through cream and yellow to a rich orange in colour. Apart from these are the equally large crimson, brown, red and bronze shades, which for depth and richness are unsurpassable. Finally, let us not forget the distinctive blue, which in some cases really is blue, although in others it is mauve or heliotrope. Selection of the seed parents in the garden will soon work wonders in the direction of blueness.

We have spoken of their utility as spring bedding plants of a high order, but one should look farther than that in the widest conception of the word garden. Nearly allied to the common primrose and sharing its love for partial shade, the polyanthus is splendid for massing, either in the orchard or the wild garden, and an ideal combination can be planned by long irregular drifts of both primrose and polyanthus, used in such a position. First, even as early as February in a mild season, one gets masses of the lovely primrose, and then, just as these are beginning to fail and fade, the polyanthus—hitherto a trifle spotty in its effect—blazes into full glory, thus prolonging the display from February to mid-April or even later.

Where used for natural plantings, the best effect is obtained from the lighter colours : the reds and crimsons have a partially foreign look that is out of consonance with their surroundings. These semi-woodland plantings are often remarkable for their lasting powers and it is no uncommon sight during the April days to see those plants that are set out in the formal beds badly flopped ; while a short distance away, 'neath the leafy trees, the stout stems and succulent leaves are sturdily upright and gorgeously beautiful in the light and shadow of the dancing sunbeams that pierce their way through the—as yet—thin overhead covering.

This brings up a cultural point of prime importance : the need for shaded summer quarters in which to grow the plants. If left in the hot, dry, sunny beds, the polyanthus becomes herbaceous instead of evergreen, and all the foliage disappears under the heat of summer, to reappear with the advent of the autumn rains. This, naturally, is extremely prejudicial to first-class flowering, and is completely avoided by planting the roots that are divided, or the seedlings that have been raised, in a border of rich soil but well in the shade.

Personally, we are all in favour of seed as *the* method of propagation, for there cannot be a question that, when seedling and divided plants are flowered side by side, everything is in favour of the former. The contention sometimes advanced that division gives larger plants is incorrect ; that is to say, if the seedlings are given proper treatment from the outset. This, combined with early sowing, will give you plants that are nearly as large as the divisions themselves by mid-June, and in the following three months the seedlings gain all the way.

Early sowing may be taken to mean one of two dates—either under glass in January or directly the seed is ripe in July in the open ground. Whichever period is favoured, sowing of the thinnest order should be practised, so that each little plant has room to develop to its utmost capacity, without hindrance from its neighbour. Sowings made in July will not flower until the following spring twelve-months, those made under glass in January requiring about fifteen months.

In the case of indoor sowings, the plants should be transferred to cold frames as speedily as possible for the sake of future sturdiness, and, in either case, pricking out should be done when the fourth or fifth leaf has been formed. A deeply worked shaded border that has been well manured two or three months previously is ideal for pricking out, and each seedling should be 8ins. to 10ins. from its neighbour. This may sound

Digitized by Google

excessive, but please remember that we are growing *large* plants, and, as a set-off against the space required, fewer of them will be needed when planting time comes. Pricking out completed (and both in the case of July or January sowings this may generally be done in early April), well water the plants overhead and repeat this at intervals—if the weather continues dry—until they are well established.

Through the spring and summer but little attention will be needed, save an occasional hoeing to keep down weeds; while, in long spells of drought, the hose may be turned on to them once a week until the soil is thoroughly soaked. Towards the end of July or early in August, surface roots begin to evolve from the neck of the collar of the plants, and this is just the moment when a top-dressing of rich earth is amply repaid. The material from beneath an old hot-bed, passed through a fine sieve, can scarcely be excelled. Work this close up to the plants, and again water well, and an almost magical output of strong deep green leaves will result.

A BORDER OF THE LIGHTER COLOURED POLYANTHUS OF THE MUNSTEAD STRAIN.

Planting in the permanent quarters should not be deferred too late into the autumn, mid-November being quite late enough for the last plantings. Lift with a good ball of earth—an easy matter, owing to the mass of fine fibrous roots—and transfer to the beds and borders with the least possible delay. The best soil is a rich, somewhat greasy yellow loam, but any soil will give superb masses of flowers if it is well manured and the soil is not allowed to become dry in March and April.

Splendid results may be obtained from seedling polyanthus where these are grown in pots and flowered in a cold frame: for not only is it possible to anticipate the outdoor display by some weeks by the aid of this protection, but absolutely spotless purity is ensured. Where a few plants are grown in this way, it is worth while to procure enough of the fibrous greasy loam—mentioned above—for potting, and, in the case of large plants, a 7in. or 8in. pot will not be too large. Drain the pots efficiently, plant in autumn, and at once transfer to cold frames: although the lights should never be entirely closed, except in the case of severe frosts. Keep always evenly moist, but avoid over-watering, and, directly the buds can be seen, begin to feed with weak liquid manure. Under this method, truly enormous flowers of intensely vivid colour will be produced and, if the pots are removed to a cool house, the successional trusses will maintain a decorative appearance for many weeks.

The alternative method of propagation—division—is useful in the case of an exceptionally good form appearing among the seedlings, for one can by this means obtain a good stock of plants comparatively rapidly, and then, by judicious crossing, seed, more or less true, may be procured. Division is a simple matter and readily carried out immediately subsequent to flowering. Lift the plant with the spade and separate into single crowns, each with a few roots attached, and immediately replant these in a semi-shaded border in exactly the same way as with seedlings. They are far more liable to droop, however, and for some days—unless the weather is showery—spray overhead through a fine-rosed can, so as to re-establish as rapidly as possible.

Like its very close relation, the primrose, the uses to which the polyanthus can be put are almost unlimited. Whether planted in beds, masses or drifts, in woodland or in the rockery, in some shaded crevice or nook facing south and west, they give abundant pleasure by their myriads of bright coloured blooms at a time when colour is lacking in the garden.

BOOKS ABOUT PLANTS.—I

GARDENING AND LITERATURE.

SO much has been written about flowers and so many people are afraid of reading about them in case they should be bored. They rush to a novel or a magazine and perhaps keep vaguely a standard book on gardens to be pulled out of the shelves and used as a work of reference. To those of my readers who read gardening books as a pleasure and may even possess a horticultural library, I say, like Farrer, "Skip, Aunt Agnes"; at the present moment I am talking to those who may not know the delights of floral literature, and who do not know where to begin.

There are lucky mortals who find delight in spending an hour in reading snippets here and there out of the Encyclopædia Britannica or Mrs. Beeton's Cookery Book. For those I can straightway advise the purchase of Nicholson's Illustrated Dictionary of Gardening, in five volumes, with supplement, a work long out of print but obtainable second-hand at about £5 5s., and a very good five guineas' worth, or Farrer's "Rock Garden, two volumes, published by Jack, or any other standard work on gardening or a class of gardening. But to those who are not such voracious readers, the first start is to find out how others love plants, and see plants, and write about plants. It matters not whether you know the plants described or not, so long as you have a genuine love of flowers, because, after all, you love flowers for their beauty and the enjoyment they give you and it is as easy, though, truth to tell, far from common, to write good English about plants as it is about anything else on which our literature is founded. Once you have become interested it is only a very short step to the fascinating subject of botanical and horticultural history, the folk lore of plants, their physical development and so on. In time, perhaps, you may, if you so wish it, desire to follow up a particular family or genus, or to discover for yourself the reasons for a plant disease or a plague of insects, and so books on specialised subjects are purchased and the nucleus of a botanical library is formed. Then again, the pictorial side may have its attractions, and volumes of books on flowers, with marvellous coloured plates will be sought for, but this is a branch which has passed its heyday, owing to the present-day cost of the best colour printing, and if the best is required, so are considerable knowledge and a deep purse.

In order to acquire a taste for gardening books as literature there are a number of old authors and at least two modern ones whose writing is full of charm and is yet information. Of the old I can bring to your notice William Lawson, whom Miss Rohde calls the Izaak Walton of Gardening. His best known book is called "A New Orchard and Garden," of which the first edition was published in 1618. It ran through many editions and the later ones can be picked up for a few shillings. It describes a North Country garden and breathes the love of the country and of flowers. Probably the most famous of all gardening books is the "Paradisus" of John Parkinson, which first appeared in 1629. Later editions are not difficult to obtain and there are also reprints. Parkinson was always inspired with the simplest delight in all garden flowers and this book is of the pleasantest reading. For those who wish to delve more deeply into the subject of old English books on gardening, before actually purchasing them, I cannot do better than advise them to read Miss E. S. Rohde's two charming books on the subject, "The Old English Herbals," published by Longmans Green in 1922, and "The Old English Gardening Books," published by Martin Hopkinson in 1924. In the first she deals with those which give lists of plants and herbs, but it is a mistake to say that they make dry reading; although they are not suitable for devouring at a gulp, yet they are crammed with quaintness and are full of garden lore. The second deals with such books as were written on the art of gardening. Both of Miss Rohde's books are excellent. They are full of quotations from the various volumes, quotations which whet your appetite to read more.

So much for the old books. New books, which combine gardening and literature, are rather more difficult to advise upon, for people nowadays are too much inclined to take up gardening as a scientific pursuit, or hobby, or whatever you like to call it, with the result that modern books on the subject are written for practical people with little thought as to their literary value. There are, however, two authors who are pre-eminently readable; one is Sir Herbert Maxwell and the other the late Reginald Farrer. As an example of the work of the former, let me commend to your notice "Flowers, A Garden Notebook," published last year by Maclehose and Jackson. In this Sir Herbert tells of his own garden at Monreith, in Wigtownshire; there may be plants mentioned therein which it is impossible to grow in less favoured parts of the country. We may envy his good fortune, but at least he shares it with us in his charming book. And of Farrer's many volumes — they are all so good and so full of rich meat that it is impossible to pick and choose. My choice, however, is made easier by the fact that a number of them are out of print. Of his two great plant-travel books, one, "On the Eaves of the World," is exceedingly scarce, but the second, and to my mind the better of the two, called "The Rainbow Bridge," is still in print and is published by Edward Arnold. In it he describes his second year's journey in the Tibeto-Kansu border and with such charm and such insight that it is surely one of the great books. There is nobody who has such power of carrying his reader with him, whether it be on the crest of a wave of enthusiasm or in the depths of despair because the harvest is not so rich as was expected. Every chapter is spiced with his experiences and his descriptions of the people and of the scenery.

I hope I am not being unfair when I say that Farrer is the outstanding feature in modern gardening literature, as apart from the gardening text books. Other of his earlier books which exhibit the same feeling and felicity of expression are "In a Yorkshire Garden," published by Edward Arnold, and "Among the Hills, a Book of Joy Among High Places," published by Headley Bros. There are others, but they deal more with specialised subjects and will be mentioned later.

By such books as these, then, you may learn that a small, and very select, library may be formed, which will combine both pleasure and profit in the pleasantest form. In further articles, I will give selections of general gardening books and also of works on specialised subjects, but it must be remembered that these are only suggestions from a list which is particularly extensive, for there is no hobby so well served by its teachers as gardening.

M. C. E.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

PLEASE REMEMBER TO MENTION "THE GARDEN" WHEN ANSWERING ADVERTISEMENTS.

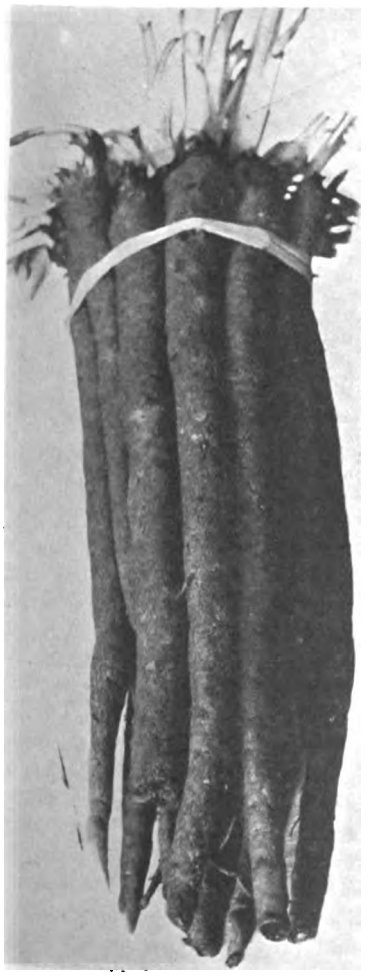
LITTLE-KNOWN VEGETABLES

IN THIS ARTICLE THE AUTHOR DESCRIBES A FEW VEGETABLES WHICH DESERVE A MORE WIDESPREAD POPULARITY IN THIS COUNTRY. THEY ARE OF EASY CULTURE AND GIVE EXCELLENT RESULTS.

A NUMBER of vegetables are not grown in England to the extent they might be. Yet, their culture is, in most cases, no more difficult than that of any other vegetable and they should be most welcome for making a change in the daily diet of many. The reason is that probably few people have heard of them or realised the possibility of growing them in their garden. Below are a few notes on some uncommon vegetables.

CHINESE ARTICHOKE (Stachys).—Although not a striking vegetable, this is worth growing in small quantity in every garden, owing to its curiosity and its ease of culture. The plant produces numerous conical, small, ring streaked, white rhizomes. Propagation is carried out by tubers planted two or three in a clump, 18ins. apart, in any good ground, during March and April. They can be lifted at any time during the following winter.

JERUSALEM ARTICHOKE.—This is more usually considered a forage or industrial plant than a vegetable. A few varieties, however, are well worthy of cultivation in the kitchen garden. Among these, Fuseau, a new variety, stands out prominently. It has, as its name implies, a smooth spindle shape, is of a light pinky colour and contains a high percentage of sugar. The common, red tubered variety can also be grown, but less conveniently. The cultivation of this vegetable is easy. Tubers planted in March in any soil give a bountiful crop the following autumn. Like the Chinese artichokes, the tubers must be lifted only as they are wanted, for they do not keep long out of the ground.



SCORZONERA, A MOST USEFUL WINTER VEGETABLE.

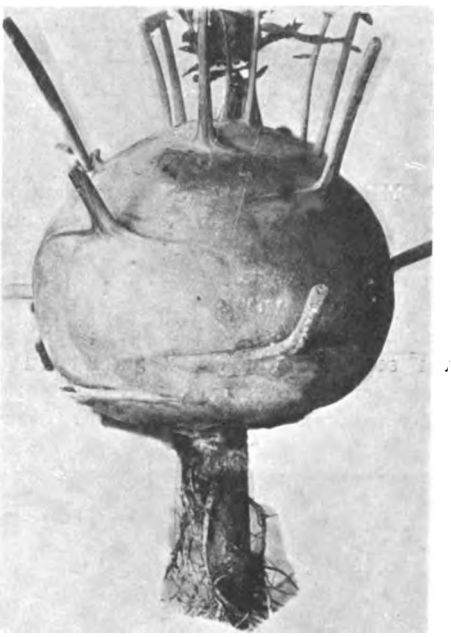
TURNIP-ROOTED CHERVIL.—A fine vegetable, rarely found in gardens nowadays; this is a great pity. The plant produces a small, white, fleshy root, similar to a small carrot, of a very refined taste and always much appreciated by the connoisseur. A very important point about this vegetable is to sow the seed in the autumn, or store the seeds in sand all the winter.

COMMON CORN SALAD.—Of very easy culture, this hardy vegetable ought to be far more grown than it is. It is certainly one of the best winter salads, and is in season from September till March. The plant forms small rosettes of vivid green or, in some varieties, light green foliage that can be eaten in the same way as every salad. Often grown as a catch crop, corn salad is sown broadcast in August after the ground has been cleared of other crops, such as onions, French beans, etc. Little trouble need be taken, the ground being just hoed superficially and then raked over for covering the seeds. For harvesting, the whole plant is simply cut with a knife.

ENDIVE.—Two kinds of endive are cultivated, one with finely lacinated foliage and the other with almost entire and serrated foliage. Endive is invaluable as a winter salad. Owing to their rather hard texture, they are bleached before consuming except, of course, when intended for cooking. Sowing takes place in July and beginning of August, and the plants, if grown in good soil, are ready to eat from October till January and February. If they are to be eaten during the early winter months, a good way to protect the plants against cold and to bleach the leaves, is to cover the beds with dry leaves and straw. It is best to transplant them to a cellar or cold frame if they are not required till the spring.

KOHL RABI.—Commonly cultivated as a forage crop, there are several varieties of kohl rabi that are useful for culinary purposes, when eaten in a young state. Unlike turnips, swedes, etc., the edible part in this plant is not the root, but the stem that becomes fleshy and spherical above ground. Probably the best variety to cultivate is Early White Short Leaved, a kind that grows quickly and is always tender. If intended for winter use kohl rabi is best sown late in the season, that is in June or first weeks of July. It has a taste half cabbage and half turnip and can be cooked in the same way as either of these vegetables.

SUGAR (or MANGE-TOUT) PEAS.—In this class of peas, pods and seeds are eaten together, owing to the absence of



THE BULBOUS STEM OF KOHL RABI SHOULD BE EATEN IN A YOUNG STATE.

fibres in the pods. These peas are exceedingly good and one wonders why they are not more commonly cultivated in England. A reason may be that the birds are very fond of them, but nets are a safe remedy. Quite a number of varieties, dwarfs and climbers, exist, among which one of the best is probably Tall White Flowering Scimitar, or Crooked Sugar, a climber. Sowing takes place, as in ordinary peas, from February-March till June and July, in good, rich, open ground.

SWEET POTATO.—Mention may be made of this curious vegetable, which is very common in the tropics, but rather difficult to grow in our northern climate. Gardeners who have greenhouses can nevertheless attempt it. Young plants are planted on an old hot bed in May or June when frosts are no longer to be feared. Plenty of room must be given them. The large, coloured tubers are ready in October. These tubers keep badly and must be used in a comparatively short time. The best way of propagation is to take cuttings every year from tubers wintered in a very dry corner of a hot greenhouse, or to root them in July and August and winter them also in a hot house.

SALSAFY and SCORZONERA.—These two vegetables are much alike, except that the first has white and the second black roots. Both are much appreciated by the epicure. The cultivation of these vegetables is easy. Seeds, which one must get from a reliable source (its germinating

Digitized by Google

power lasting only one year), are sown in March in deep ground in rows 1ft. apart. They ripen during the winter, while scorzonera, which is a true perennial, will last for several years.

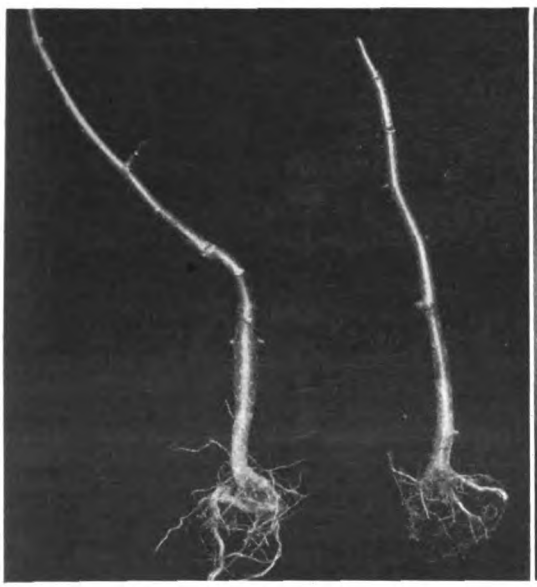
NEW ZEALAND SPINACH is essentially a sun and heat lover. It is sown at the end of May in pots in a greenhouse or in a frame and planted when large enough in the open air. An ideal place to plant it is on an old hot-bed where plenty of moisture can be given. The leaves, which can be cut all the summer, have the same flavour as ordinary spinach.

YAM (Chinese).—The old variety of Chinese yam had the great disadvantage of being too long (often 2ft. to 3ft.), and so was very difficult to lift. Of late, however, a variety, "Chappelier's Improved" has made its appearance, which can be recommended. The tubers are about 1ft. long, yellowish and in the shape of a club. The cultivation of the yam is fairly easy. After lifting, the thin top part of the tubers is retained, cut into lengths of 1½ins. or 2ins., which are put in sand in a cellar till March, when they are started into growth in a house and planted in the open during May or June in deep, rich ground. The plants can be left two or more years on the same spot without disturbance. C. L., *Paris.*

PENTAPTERYGIUM SERPENS

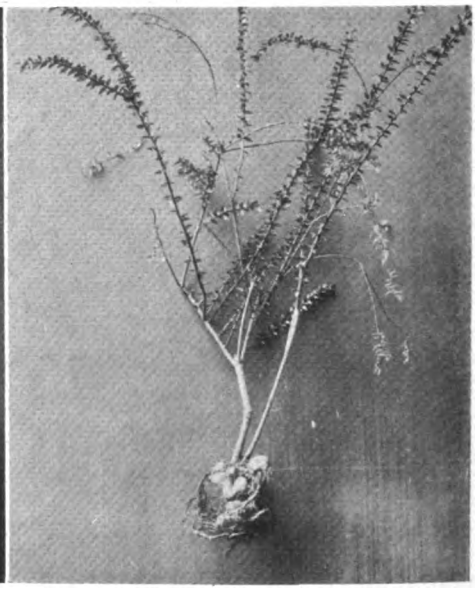
BY L. B. STEWART

SOME time ago there appeared an article in THE GARDEN (July 12th, 1924, page 489), on the fruiting of this plant by Miss M. Mitchell. The fruit, after the drawing had been made, was taken and the seeds extricated. They were thickly coated with mucilage, and after sowing were not very long in showing signs of germination. After three weeks the seedlings which had germinated began to show the characteristic swelling of the root-stock—the swelling taking place from the primary tap root. When the swelling begins to take place the seedlings commence to press this swollen portion on to the top of the soil, and from the base of this swollen portion other ground roots are formed. The small root-stock is circular in shape and uniform, but whether it will keep this uniform shape is very difficult to say at present. The object in sowing the seed, however, was to find out if it was fertile or not, as the plant is very easily propagated from stem cuttings, which is the method usually adopted in this garden. The interesting point, however, is that it is the primary tap root which gives rise to this swelling at a very early stage, whereas with the cutting it takes a considerable period before the roots begin to show this swollen root-stock, and although the swelling makes its appearance it is never so regular and uniform as it is in the seedling. The length of time taken by the cutting to produce this swelling may be due to the fact that the kind of root to be produced is not present among the first roots sent out, but is a later development. When a cutting begins to form this swelling it grows upwards in the pot. After it has attained a certain size and has grown out from the stem there is a gradual bending downwards of the point end of the swollen portion. After the swollen portion gets into position it is gradually pushed up until it is above the level of the ground. Its irregular shape may be the result of this bending. The cutting certainly never has the appearance of the seedling, and often sends out two or more of these swollen fleshy root-stocks. It is, however, quite the reverse in propagating plants which have a highly developed hypocotyl, such as is found in Sterculia rupestris.



On the left.—SEEDLING OF BURSERA SHOWING WELL DEVELOPED HYPOCOTYL. *On the right.*—STEM CUTTING.

A THREE WEEKS OLD SEEDLING OF P. SERPENS SHOWING THE REGULAR SWOLLEN ROOT-STOCK.



STEM CUTTING OF PENTAPTERYGIUM SERPENS WITH THE IRREGULARLY SWOLLEN ROOT-STOCK.

Here one finds that the hypocotyl has grown into an enormous size when the plant has been raised from seed, but should cuttings of this plant be rooted it will be found that no swelling takes place. The plant having lost its characteristic, by the absence of the swollen portion, is difficult to distinguish.

Many other plants show highly developed hypocotyls—such as Bursera—which are of high economic value, and great care has to be taken to prevent the hypocotyl from being buried. At Edinburgh they are always potted with the roots showing on the surface of the soil. When branch cuttings are rooted they can be handled with impunity, as it does not seem to be of any importance to them how they are potted, and shows the grower that he has got rid of the dangerous part of the plant. Whether or not this mode of propagating Bursera commercially would prove to be a success, has yet to be evinced, and I expect much would depend on the growth of the cutting compared with the growth of the seedling.

SOME ROSES FOR THE WILD GARDEN

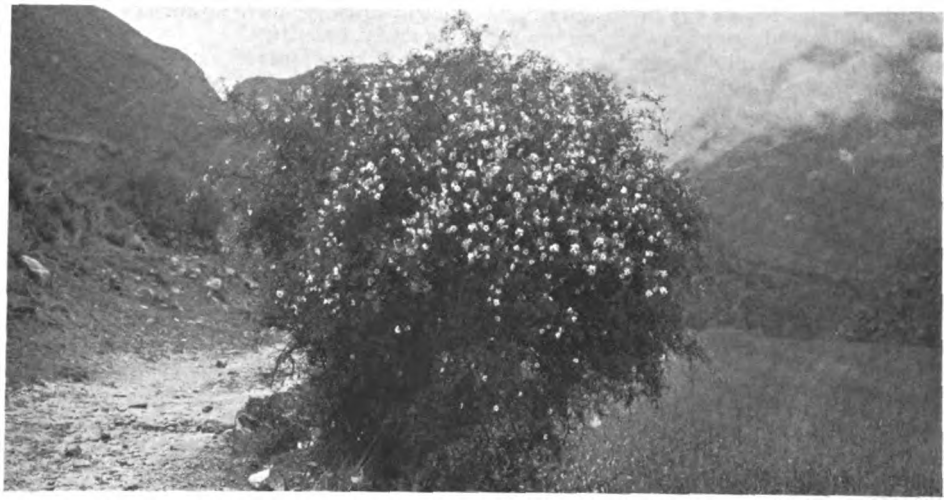
BY E. H. WILSON.

ROSA SOULIEANA.

THIS is an extremely vigorous species of musk rose, common between 6,000ft. and 10,000ft. in the warm, dry valleys of the rugged region which forms the Chino-Tibetan borderland. When isolated it forms dome-shaped, tangled masses 20ft. high and as much through, but on the edge of the forests it is more rampant. It has grey stems which, as in all its class are freely armed with hooked prickles. Its leaves are grey-green and the flowers, borne profusely in flattened round clusters, open yellowish and change to white.

The fruit is ovoid and orange red. The flowers are each about 1½ins. in diameter and the trusses from 5ins. to 6ins. through. It was discovered near Tachien-lu by Père Soulie of illustrious memory, who sent in 1896 seeds to M. Maurice de Vilmorin, with whom it first flowered in 1899.

Though native of an upland region this rose has not proved hardy in the Arnold Arboretum, though it flourishes at Kew where it has been growing for a quarter of a century. It is well adapted for the wild garden, where it can ramble at will and, untouched by the pruning knife, display the beauty of its flowers, its luxuriant foliage and attractive fruits.



ROSA SOULIEANA ON ITS NATIVE HEATH IN THE CHINO-TIBETAN BORDERLAND.

ROSA MULTIFLORA CATHAYENSIS.

With its pink blossoms and bright yellow anthers this is one of the prettiest of wild roses and, moreover, one of the most interesting. It is a common rose in China, favouring sandy and rocky places beside streams up to altitudes of 6,000ft. In habit it is variable, for the stems may be prostrate or erect. but it is best as a bush from 5ft. to 8ft. tall. On rocks it generally forms a dense mass with arching stems. The flowers are produced in erect flattened clusters, which, standing well above the foliage, garland the whole plant in pink of the purest hue.

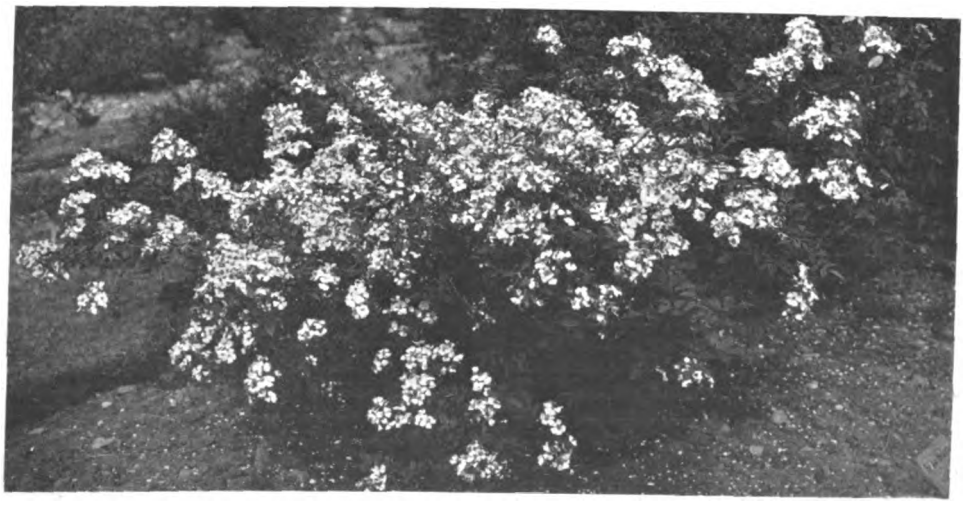
This rose is the wild parent of the Polyantha rose, the old "Seven Sisters Rose," and of the famous rose "Crimson Rambler," which have been cultivated in China probably for centuries and long before they were known in Western gardens. Of perfect hardiness, this wild form is more lovely than many of the modern rambler roses raised and grown in the West and is worthy of a place in gardens where beauty in simple flowers is appreciated.

Forms of this rose with double flowers were introduced into England as long ago as 1804, but the wilding itself was apparently quite unknown in Western gardens prior to 1907, when I sent seeds to the Arnold Arboretum.

ROSA MULTIFLORA CATHAYENSIS. A BEAUTIFUL WILD RAMBLER WITH PINK BLOSSOMS, FOUND IN SANDY AND ROCKY POSITIONS.

ROSA HELENÆ.

Of the half dozen and more musk roses of China, Rosa Helenæ has proved the hardiest of those introduced into Western gardens. It is an exceedingly



THE HARDIEST OF ALL THE MUSK ROSES WHICH HAVE BEEN INTRODUCED TO WESTERN GARDENS IS ROSA HELENÆ

Digitized by Google

common rose in the mountains of Central China, its blossoms perfuming the countryside in June. It is a strong grower with arching canes from 6ft. to 12ft. long, plenteously armed with stout, hooked prickles. The leaves are from seven to nine foliolate, deep green above, grey-green below, sharply toothed and glabrous except on the petioles and principal nerves on the lower surface. Along the full length of stout canes short shoots are developed, each terminating in a large, rounded cluster of pure white, delightfully fragrant flowers, which are followed by orange to red, ovoid to obovoid hips. The individual flowers are about 1½ins. across with a cluster of conspicuous yellow stamens and are singularly beautiful.

In rocky places from river level to elevation of 5,000ft. this rose is abundant in Western Hupeh and Eastern Szechuan, but it has not yet been reported from farther west. In wayside thickets and on the banks of streams it forms dense masses often 20ft. high and as much through, and on the margins of woods it entangles and drapes small trees. At the Arnold Arboretum it is quite hardy, withstanding as much as 45° F. of frost. On limestone soil at Rochester, New York, it thrives even better than around Boston, Mass. The author's appreciation of the musk rose may be gauged from the fact that it is named after his wife.

THE FIG

THE fig, one of the most delicious of all fruits, is often overlooked and not grown, yet it is quite certain that no choice or dainty sweetmeat excels a White Ischia fig when, growing in a sunny position, it is bursting with ripeness.

The fig may be a somewhat unappreciated fruit because an imported green fig, picked unripe, as it must be, bears no comparison in flavour with the home-grown fruit picked ripe.

Again, the cultivation, in no way difficult, is different from other fruits. It is more fruitful on poor soils than on rich, yet when carrying its fruit pays for feeding with liquid manure.

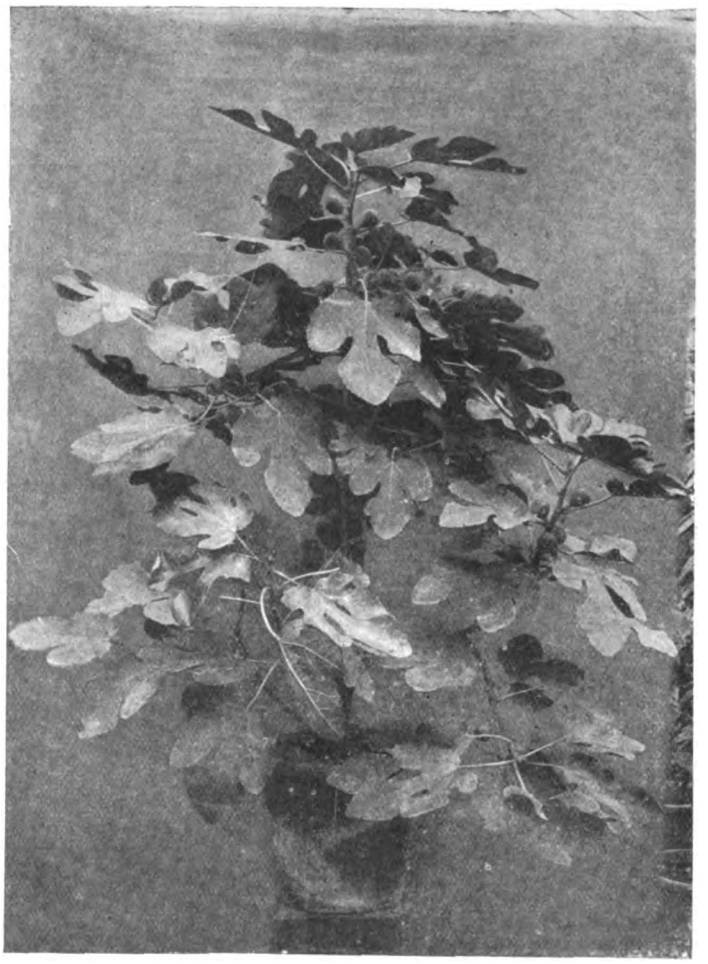
Under glass, if forced, the fig may produce three crops of fruit a year, while two crops (one coming on the previous season's wood and one on young wood) may be expected on trees in an unheated house if grown against a hot wall.

Outside, the fig succeeds well on a south or west wall for preference, as it is in such places where red spider would be rampant on some plants, that the fig is at home. Without the reflected heat of a wall the successful crop of fruit is less certain, but quite possible in some districts. Most important details outside are restriction of the roots and selection of varieties.

In the open, and especially in rich or deep soils, the roots should be confined to a restricted area, or the trees produce an excess of fruitless growths; a brick or concrete floor 2ft. down will secure the tree against a downward tendency of the roots, which should afterwards be pruned if the tree develops too grossly.

Visitors to the East Coast town of Deal may obtain a good lesson in fig-growing in the moat in Deal Castle, against the walls in shallow soil. The fig likes a soil in which lime is present and mortar rubble or chalk are valuable ingredients of the soil. Grown in this suitable but poor soil, liquid manure produces immediate results if applied when fruits are swelling. Brown Turkey and Brunswick are the two recognised varieties for outside, but others will do in a warm position.

Under glass, when grown in pots, the cultivation of the fig is quite easy.



THE FIG MAKES AN EXCELLENT POT PLANT.

If planted in a border it is essential to restrict the roots, while at the same time to see that there is ample drainage, for a water-logged soil will not do. For the same reason, when in pots the compost should be open, the loam lumpy and unscreened, in proportions of two-thirds of the latter to one-third sand, manure (rotted), mortar rubble or chalk in equal proportions, and some bone-meal or hoof and horn is a good addition, at the rate of a 7in. potful to the barrow-load. Pots should be double crocked, or, better still, have a layer of ½in. bones to ensure good drainage.

An additional interest may be found in the fig, which is the first tree mentioned in the oldest book and history of the world; but to the modern and materialistic mind its luscious flavour and ease of cultivation should be an attraction. It is quite a popular fallacy that the appreciation of the green fig is an "acquired taste," and I have never met the individual who did not admit to this after tasting a fully ripe White Ischia. It was the late Mr. George Bunyard, a fine judge of quality and flavour, and the greatest connoisseur of good fruits in his day, who first pointed this out to me.

The different varieties are worth a little study, for most of them have their good points. My selection of the best would be as follows, placed somewhat in their order of general merit:

BROWN TURKEY, the most easily grown inside or out. Large, with brown skin and red flesh, very luscious.

WHITE ISCHIA, small, but very sweet. Skin and flesh pale yellow. Very free bearing.

BLACK ISCHIA, somewhat similar to the latter, but larger, with deep red flesh.

NEGRO LARGO, the largest fig grown, with the finest appearance, but not so fruitful as others. Skin black, flesh pale green, tender and juicy.

BRUNSWICK, good for inside or out. Forces well. The large fruits are brown, with purple flesh of high flavour.

BOURJASSOTTE GRISE, fruit of good size, with blood red flesh, juice thick and syrupy. One of the best.

VIOLETTE SEPOR, large fruits, skin brownish purple, flesh deep red. Excellent flavour.

WHITE MARSEILLES, one of the best early varieties to force. Skin pale green, flesh opaline.

OSBORNE'S PROLIFIC, an excellent variety for early work and forcing. Skin brown, flesh white, good quality.

Growing any fruit is a fascinating hobby and a profitable occupation; the cultivation of figs is not the least absorbing, as those who have a greenhouse or a warm corner outside will prove if they give them a trial. L. J. COOK.

WINTER SPRAYING

LAST season was remarkable for its exceptional freedom from plagues of aphides, or "blight," as the countryman calls the whole tribe of green fly and its relatives, but what we gained by the absence of these pests was to a great extent lost through the vigorous offensives of hosts of caterpillars. The various mites, maggots and grubs that infest apples and pears, and a whole catalogue of parasitic fungoid diseases of large and small fruits, roses, and some ornamental trees, have made a merry time of it at the expense of orchard and garden owners, and the truth of the matter is that the need for spraying is urgent.

The old familiar admonition in regard to the necessity for spraying before the enemies gain a foothold, and the folly of waiting until serious damage has been done must, when one comes to think of it, have fallen on many deaf ears. That is the great handicap to progress, but it is very difficult to induce anyone to spend money, time and labour upon the task of fighting an unseen foe. Let one see his plum trees, and the young growths of apple trees or of roses smothered with green fly and away he will go for "Abol" or V. 2 Fluid, or nicotine wash and give the pests an uncomfortable half hour, but talk about green fly in the wintertime when the trees are bare, and it is like trying to interest him in a scheme for protecting Southend shrimpers against sharks. When mildew whitens the foliage of roses and vines the quest for cures begins, but how like the voice that cries in the wilderness is the plea for spraying against mildew with a copper sulphate spray, or with lime, sulphur and salt, while growth is dormant; and yet, careful and practical tests have proved that even the more susceptible roses and vines in houses which have to accommodate other kinds of plants can be kept clean and healthy by the winter use of one of these sprays.

The preparation of such spray fluids is quite a reasonable undertaking for extensive commercial establishments where many acres of fruit trees or roses have to be dealt with, but for private gardens it is cheap—probably cheaper—and certainly less messy and troublesome, to purchase one of the ready-made pastes or compounds which are put up in convenient quantities with explicit instructions as to how they should be mixed with water.

The ordinary rose mildew (Sphærotheca pannosa) does not expire or migrate when, with the withering and fall of the foliage, its downy whiteness disappears, but it perfects its minute fruits, which under a powerful microscope have somewhat the appearance of half-formed blackberries with radiating hair-like filaments around the base, by which they attach themselves to stems, thorns, or to soil and stones around the base of the bush. These fruits remain dormant until spring, when they release multitudes of spores to develop their downy coating over the young growths as soon as weather conditions are favourable. Bordeaux mixture, sprayed during the dormant season, will not harm the hard wood of the bushes, but will prevent the fruits of mildew releasing their spores. Cupram is a good spray to use on vines, peaches, etc., and it is effective against peach-leaf-curl as well as mildew. Cupram is made by mixing copper carbonate with ammonia but this again is much better obtained from qualified horticultural chemists.

It is during the dormant season that the best work can be done among fruit trees which are green and slimy with lichen and algæ. It seems strange that there should still be necessity for urging the importance of cleansing the bark of fruit trees and many ornamental trees also, but basing judgment upon the number of trees allowed to retain loathsome coats of greasy slime and green mossy fungus, one is driven to the conclusion that many owners of gardens are yet ignorant of the fact that these filthy coatings are not mere disfigurements, but are injurious impediments to the natural functions of the respiratory pores of the bark. One would imagine that if the sole result were to allow access to the tree for pruning or fruit gathering without getting besmeared with slime, it would be well worth spraying with a caustic alkali wash, but when the health and productivity of the tree are also at stake no legitimate excuse for the careless neglect that is so prevalent is to be found.

Still further to urge the folly of neglect in this matter, it is a fact proven beyond contention that the eggs of the most destructive of insect pests lie secreted and snug among the lichen of tree trunks, and by the destruction of the lichen the safe harbour for a myriad of pests is routed, and thus the caustic winter wash performs a triple service. Strawsons, Coopers, Abol and a number of other familiar names among horticultural chemists occur to mind as providers of excellent caustic winter washes, the basis of which is caustic soda. Needless to say the use of such preparations is work for intelligent men who, realising the nature of the compound they are using will exercise due caution that the spray is driven on to the trees to be treated and not over the faces and clothes of passers by. The operator will also be well advised to smear his face and hands with vaseline, and to take care to keep himself to the leeward side of the spray throughout the operation. A still day, rather than a windy one should be chosen for the work, and it is very essential that the machine should be thoroughly washed inside and out as soon as spraying ceases.

It is utterly inadequate and hopeless to rely upon one spraying, however thoroughly it may be performed, completely to restore to health old trees that have fallen victims to a variety of pests and diseases. Bear in mind that one pest or one disease opens up the way for another. Aphides weaken growth, and throw the shoots open to various fungi. American blight makes sores in the bark which let in canker, and so one might go on through a lengthy list of foes which dovetail, support and follow up each other's operations like the units of a mighty army intent upon vanquishing the victims of their force.

The caustic wash clears the way for effective application of Bordeaux mixture, and it is well to mention that even canker yields to persistent effort with this copper and lime spray, which may, however, have to be used in stubborn cases for two or three successive years.

Lime-sulphur may, with advantage, be used a little later in the season, because not only will it prevent the hatching out of the first batches of aphides, but, applied in February, when the birds are prone to amuse themselves pecking out the fruit buds, lime-sulphur makes the buds unpalatable, and feathered marauders prefer to go elsewhere.

The firm of Lewis Berger has paid great attention to the preparation of a first-class lime-sulphur spray, and simple as it may appear, to read a formula for the making of such a spray and carry out the instructions, the best results can only be obtained by the most careful attention to the purity and relative strength of the ingredients to ensure an absolutely accurate balance.

Gooseberries, currants, loganberries and blackberries may all, with advantage, be sprayed with lime-sulphur as well as the tree fruits.

Many times I have urged that where a garden is surrounded by hedges of thorn, myrobalan, dog briar, etc., or where trees which harbour pests and diseases are within easy distance of the garden or orchard, it is well worth while when the job is afoot to douch these likely hosts or purveyors of the foes that are to be fought. There is no extravagance in using a gallon or two of wash and an hour or two of time to extinguish possible relays of the enemy, but there will be a good deal of labour in vain if this is neglected.

As spring advances, other pests need other poisons. Nicotine becomes extremely valuable when biting insects become active. Whenever nicotine is mentioned the name of G. H. Richards, Borough High Street, S.E., is called to mind, for his nicotine preparations must have a marvellous record of slaughter among the foes of the garden. XL All is an invaluable symbol of efficiency in insecticides, not only the tree wash, but the fumigating compound, which is a boon where glasshouses are concerned.

I have for years made a practice of adding a few drops of XL All Fumigating compound to all my ordinary soft soap-quassia sprays, and the effect of such reinforcement is very remarkable. If I were obliged to restrict myself to one insecticide, nicotine would be my choice. Psylla, and the terribly destructive capsid bug require this narcotic poison; and in spring, too, the use of arsenate of lead must be considered, especially if from any cause the trees were not effectively grease-banded to trap the wily wingless winter moths.

Rather than dismay the reader with a prolonged spraying programme for the

Digitized by Google

whole season, however, let it suffice for the present to reiterate the wisdom of concentration for a time upon caustic soda, copper and lime-sulphur in that order of rotation.

Owners of small gardens are somewhat handicapped because, while they can procure serviceable spray fluids in small quantity, they cannot obtain a spraying machine which just suffices for their small needs, and do not feel justified in paying the price of a good knapsack. To such an "Abol" syringe is a real treasure. It will discharge as fine a spray as a machine at treble its cost, and it is, moreover, an implement for which there are useful and necessary tasks during the greater part of the year. In fact, no garden is too small to require a syringe, and no garden requires a better one than an "Abol." The excellent insecticides bearing the same name are also praiseworthy, being safe and efficient during the whole active season of all kinds of biting and sucking insects. Owners of greenhouses will even now find work for "Abol" insecticide; its outdoor use will commence with the appearance of young spring foliage. A. J. MACSELF.

CORRESPONDENCE

FLOWERS IN A CORNISH GARDEN IN DECEMBER.

SIR,—Readers of THE GARDEN may be interested to see the enclosed list of one hundred and eleven flowers in bloom out of doors in my garden, December 31, 1924.—CORNISH GARDEN.

Cyclamen coum
C. europæum
Viburnum lucidum
V. Tinus
V. rotundifolium
Olearia Forsteri
O. F. grandiflora
O. stellulata
O. Gunniana
Choisya ternata
Raphiolepis ovata
Diosma gracilis
Pernettya mucronata
Acacia Baileyana
A. ovata
A. retinoides
Osmanthus ilicifolius
Banksia buxifolia
Abelia chinensis
Abutilon
Veronica (3 varieties)
Aponogeton
Aralia Sieboldii
Grevillea rosmarinifolia
G. sulphurea
G. Preissei
Escallonia rubra
E. exoniensis
Erica carnea rosea
E. codonodes
E. arborea
E. Veitchii
Hypericum patulum Henryii
H. calycinum
Hamamelis mollis
Calceolaria Burbidgei
Hellebore
Genista
Diplacus glutinosus
Solanum jasminoides
Sollya Drummondi
Habrothamnus fasciculatus
Jasminum nudiflorum
Kerria japonica
Coronilla
Clianthus puniceus alba
Hydrangea (blue)
H. Menziesii
H. quercifolia
Primula helodoxa
Arbutus
Senecio
Magnolia grandiflora
Rhododendron Nobleanum
R. N. venusta
R. arboreum seedling
R. Shirleyi
R. Strategist
Eupatorium
Ceanothus Gloire de Versailles
Correa cardinalis
C. corymbosa
Garrya elliptica
Fuchsia speciosa
F. fulgens
F. spectabilis
Brugmansia lutea
B. bicolor
Berberis Darwinii
B. nepalensis
Cytisus præcox
C. proliferus
Cistus purpureus
Azalea amœna
Hibbertia
Cassia corymbosa
Dendromecon rigidum
Primula Fosteri
Mesembryanthemum
Violet, double
Violet, single
Primrose
Crocus (blue)
Geranium (4 varieties)
Polyanthus
Aubrietia
Iris stylosa
Stock, double
Stock, single
Wallflower
Rock Cress
Geum Mrs. Bradshaw
Forget-me-not
Alyssum
Chrysanthemum (4 varieties)
Marguerite
Rose Eugene Resal
R. Ards Rover
R. Excelsa
R. White Dorothy Perkins
Salvia (3 varieties)

[It may be interesting to our readers to compare this list with that given by another of our correspondents in the issue of January 10, 1925, page 25, from West Porlock, Somerset. It also serves as a useful indication of the climatic conditions which prevail in the south-west corner of England.—ED.]

A FINE BROMELIAD.

SIR,—I enclose a photograph taken on December 20th, 1924, which may interest your readers. The plant is, I believe, Rhodostachys andina (Chili). The inflorescence consists of a number of flowers packed tightly together, and is of a pale blue colour. What made it more striking was that all the leaf spikes round it turned a deep crimson. The plant was given to me by Mr. R. C. McM. Smyth, and came originally, I believe, from Sir Frederick Moore. It has been in its present position in my rock garden for three years, but has never shown flower before. I believe these rhodostachys rarely flower in the open air, and it seems very extraordinary that this particular plant should have chosen December for the purpose! I should be glad to hear if any of your readers have had a similar experience.—ALAN MCMULLEN, *Kingstown, Co. Dublin.*

RHODOSTACHYS ANDINA IN FLOWER OUT OF DOORS.

A FLOWERING ALOE.

SIR,—With reference to Mr. William Clark's note in the Correspondence columns of THE GARDEN of November 29th, 1924, page 811, and his question as to whether the aloe figured will die after flowering, I may say that I never knew an old plant to survive after flowering, but plenty of smaller plants will probably spring up around the old plant—at least, that is my experience, having lived for thirty-three years in Latitude 34, Southern Hemisphere, where these plants are like weeds.—VERE CALDWELL.

VEGETABLE SEEDS FOR A SMALL SUBURBAN GARDEN.

SIR,—If the writer who signs himself George Garner under "Simple Gardening" is the same as we have known and learnt from in past years, he will, I know, allow me to criticise his sowing table page 13.

Would he really advise the owner of such a garden to sow a drill 100ft. long with an ounce of Globe artichoke seed? The plants grow rapidly and would by autumn cover a space 6ft. wide = 600 sq. ft.! Again, I have on several occasions sown packets of this plant from noted seed houses, but found the seedlings very variable, only about 10 per cent. being of good quality.

Broccoli is to be grown and ½oz. of seed is allowed. Probably this would produce 1,000 plants and more, but they would all be of one variety! Even a small garden would require three varieties—early, mid-season and late—to say nothing of early purple sprouting, one of the best winter vegetables for a small garden.

Celery seed is very minute and ½oz. would be sufficient for a very large garden, whereas the smallest packet would suffice for the garden named. The same might be said of the 1oz. of leek seed recommended.

If a pint of dwarf bean seed is necessary (800 average sized seed go to the pint), the allowance of two pints of peas can only be regarded as very scanty, especially as no fewer than 6,000 head of the cabbage tribe are arranged for.—J. COMBER.

CROCUS IRIDIFLORUS.

SIR,—There are some most exquisite flowers among the true autumn-flowering crocuses, and, for those who appreciate the quiet, yet bright beauty of the charming cups of the crocus in the waning days, they present much to give them delight. I hardly know one of the species which is not of high beauty, yet, of course, there are some with paramount claims upon our affections. Such is Crocus iridiflorus, one of the most exquisite of all crocuses, though inferior in size to C. speciosus and the spring-flowering varieties of C. vernus. It is of unique form among the crocuses, the difference in the size of the inner and outer segments giving it something of the appearance of an iris, hence the name of iridiflorus, or iris-flowered. This distinction caused some botanists to confer upon it the honour of a separate genus, calling it crocoiris. But it is a true crocus, and amazingly beautiful. Its cups, of a kind of lavender, varied by the inner and outer segments being of different shades, are delightful and are enhanced in beauty by the striking coloured stigmata. It is my favourite autumn crocus, and, although more expensive than some of its allies, which also flower in autumn, is well worth the few pence a single corm will cost, and a dozen or more will not be more expensive than will be justified by the pleasure they will afford for a long succession of years. It flowers in September and following months, and is perfectly hardy. Mice are its only enemies, although a slug may take a fancy to indulge itself to the luxury of a trial of its delicate flowers. This crocus is not nearly enough known, and in sunny nooks of the rock garden or border it is exquisite. I hesitate to suggest it, but a sheet of glass above will prolong its charms for a longer period—S. ARNOTT.

SIMPLE GARDENING

DAHLIAS.

THERE are dahlias to be obtained now that will suit every garden, whether used in beds for furnishing the garden with masses of flowers, in shrubberies or for exhibition purposes. They include cactus, decorative, collarette, pompon and single-flowered. It is very interesting work growing dahlias from seed, and amateur cultivators may succeed well with them, especially the single-flowered section. The seeds should be sown about 1in. apart in deep pans filled with a good gritty compost during the early part of February. Of course, some artificial heat is necessary, a warm pit or greenhouse in which zonal pelargoniums are doing well will suit the dahlias. But it is with the raising of new stock from cuttings that we are mainly concerned about now. Readers of THE GARDEN who possess old roots should examine them very soon, now, during open weather, not while a frost prevails, and make due preparations for striking the first batch of cuttings. The latter may be rooted in a propagating frame in a heated house, or in an ordinary frame placed on a hot-bed. The inexperienced cultivator would do well to use the house and propagating frame for the earliest cuttings, as they are so liable to damp off on a hot-bed. First, place the old tubers in a box of soil and encourage the growth of suitable cuttings. These should be about 6ins. long, prepared similarly to a pelargonium cutting and inserted in a nice gritty compost. After the first watering be watchful against damping off. A little ventilation will help to preserve them if applied judiciously.

FORCING VINES.

Grape vines grown under glass are forced at all times between November and April; before Christmas by fire heat solely; immediately after, mainly by fire heat, the sun heat helping; and from the end of January onwards by fire heat much supplemented by that from the sun. Where sun heat alone is relied upon the vines begin to grow from four to six weeks earlier than those on outside walls. Late varieties of grapes need a longer period of growth than the early ones. To economise as regards fuel, the early varieties may be started by sun heat alone and mature the berries in due course. But the late ones, such as Muscat of Alexandria, Gros Colmar, Alicante, will require the assistance of fire heat and to be started by its aid several weeks before the date when it is safe to start the early varieties such as Black Hamburgh, Foster's Seedling, Buckland Sweetwater and Madresfield Court. The earlier the date of starting vines the more difficult the work is; the later in the spring the easier it is because the sun has greater power and the sap is rising more freely. Having pruned the vines at the right time the danger from excessive bleeding will not be great when the sap rises. Heat and moisture are essential to induce the growth of healthy young shoots. Every morning, except in frosty weather, the rods should be syringed with tepid water; the rods should be dry at sunset. A temperature of 60° Fahr. by day and 55° Fahr. at night will answer well till the young shoots are 1in. long, then 5° more will be beneficial.

THE NEW ROCKERY.

The present is a good time to do much renovation work in the rockery garden, and also to build the new rockery, whether this be small or extensive. I use the word "build": it applies in the case of a rockery as well as in that of a wall, only the work is carried out in a different way. The drawings are made with a view to helping the inexperienced. A section is shown at *a*, it is the wrong way to place the stones; the right way is shown in the section *b*, where the

stones are properly placed. The front of a rockery is shown at *c*; the plants, shown at *d*, have plenty of soil to grow in, and the stones, when placed as shown at *b*, do not prevent the rainwater entering the soil as it trickles down from stone to stone and soil. Rockery stones should be laid flat, showing the grain, and not on end, as they are placed at *a*. When a rock wall is built the stones must be correctly placed. A small, well arranged rockery is more pleasing than a large one badly arranged. The following plants will be sufficient for a small rockery to begin with. To bloom in spring: Alyssum saxatile compactum, antennaria, arabis, aubrietia, dianthus (alpine pinks), gentiana, irises (dwarf), phlox (dwarf), primulas, saxifrages. To bloom in summer: achilleas, Arenaria balearica, asters (alpine), campanula (dwarf), dianthus, primulas, Saxifraga longifolia, sedums, sempervivums, silene, veronica, auriculas (alpine), cyclamen. Cerastium tomentosum should not be used; in many cases it soon overruns the rockery and is difficult to eradicate.

POTTING CHRYSANTHEMUMS.

The first batch of cuttings, inserted early in December, will now possess a few roots and soon be in a fit condition to be potted. When the roots reach the sides of the small pots they are well advanced in the case of cuttings inserted singly in the centre of the soil in small pots. Those inserted round the sides of larger pots will need repotting or potting singly where one plant to a pot is the rule. This shift should take place directly the young roots are about ½in. in length. If the cuttings are allowed to remain in the cutting pots until the roots are entwined together the check will be much greater than would be the case if the potting was done much sooner; and checks to growth should be avoided as much as possible.

Having decided to remove the rooted cuttings from the propagating frame, place them forthwith in another one or in a box where they can be very freely ventilated for several days prior to their removal to a high shelf or stage in the greenhouse. Very careful watering will be necessary, a light spraying being sufficient in most cases for the few days the young plants remain on the shelf before they are potted. The compost should be a simple one, fibrous loam two-thirds, leaf-soil one-third, with a good sprinkling of coarse sand or old mortar rubble added. Pass all through ½in. mesh sieve; use clean pots and crocks and return the newly potted plants to the shelf.

BIG LEEKS AND ONIONS.

The cultivator of vegetables is generally enthusiastic about all details connected with the growing of big leeks and onions. Even the experienced cultivator takes heed of hints regarding management. Indeed, it is this alertness that enables a cultivator to grow the large specimens we often see at the exhibitions. I am not dealing with the merits or demerits of such specimens here, but simply their treatment. After very many years' experience I find it is much better to sow the seeds late in January rather than early. The seedlings raised early rarely grow as freely as those raised, say, three weeks later. Many plants that suffer a check owing to early sowing of seeds, run to seed, "bolt," and are worthless. Sow the seeds in boxes about 4ins. deep. Place a very thin layer of well rotted manure in the bottom of the box, then the compost—fibrous loam two-thirds, old mortar rubble and leaf-soil combined one-third. Pass these ingredients through a ½in. mesh sieve; the reason for this is that when the resultant seedlings are transplanted the soil falls away from the roots without breaking them—a very important point. Do not use any of the fibrous portion in the bottom of the box for the same reason. Sow the seeds thinly on a watered level surface and cover them lightly.

GEORGE GARNER.

BOOK REVIEW

AT the present rate of development of our knowledge in all scientific subjects—leading to an ever increasing specialisation, with the consequent formation of many new branches in each study—it becomes increasingly important that the elementary student when he commences to dip into the realms and mysteries of science, whatever his branch may be, should be furnished with as broad an outlook as possible, embracing all the main points of all these separate threads, yet showing as far as possible the correlation which exists between them all. At the present day the relationship between these branches of a subject is apt to be lost sight of. They become as islands on a wide expanse of ocean, and consequently the beginner, unless he be of a critical and observant nature, is altogether misled as to the confines of his subject. Elementary text books these days are hence not judged according to the material they contain, but rather by the manner in which the subject matter is presented, so that the elementary student may find a sufficiency of pegs on which to hang his facts, and also that those pegs may be adjusted to fit their allotted holes. Everyone, before he can become a specialist, must have a firm and secure basis or groundwork on which to build his specialised knowledge, otherwise his specialisation, through the lacking of the fundamental and basic laws which govern all scientific theories, may probably crumble like the house which was built upon the sand. These notes are applicable to botanical study especially, and arise out of the volume which we have under review, "A Text Book of General Botany," by the Botanical Staff of the University of Wisconsin (Macmillan Company, New York, 16s. net). The book is the result of the experience of the authors in the teaching of elementary botany in that University in the first year courses, and as such appears to be most comprehensive for such a short period as three terms. Throughout its pages, however, there is a sustaining interest, since the authors have attempted, more or less successfully, to present the subject as an unbroken whole, while at the same time indicating how the various side-lines hold and offer untold opportunities for the workers in that particular direction. The intimate correlation which exists between form and function and which is so necessary for the elementary mind to grasp is not lost sight of. It is pointed out in many different aspects. The general treatment of the subject, if followed as outlined in the chapters is a good one, as it serves to present these many isolated facts as links in a continuous evolutionary chain or sequence of events. Starting from the simple cell of which the structure and functions are well discussed, the authors work through the main parts of the plants. A few chapters on elementary physiology follow, after which the reader commences at the lowest rung in the ladder of plant life, namely, the algæ and fungi, and is conducted through these to the mosses and liverworts, from thence to the ferns, gymnosperms and on to our present-day flowering plants, the angiosperms. These groups are illustrated by means of selected types, which method, although attended with many evils, has, of necessity, to be followed by all teachers of such a wide subject in an elementary classroom. The chapter on the classification and families of the flowering plants is, in our opinion, perhaps too brief; more space might have been devoted to it and less to the chapters on the lower groups, as, after all, these are subservient to the typical flowering plants in such a text book, where the student first and foremost should become thoroughly acquainted with the flowering plants as far as lies in his power after a year's study. Several chapters towards the end are of general interest, notably two on Inheritance, Variation and Evolution, where all the known fundamental facts are clearly and concisely expressed for the benefit of the beginner. A useful concluding chapter serves to present to the reader the economic importance and significance of plants in the general scheme of things. It is copiously illustrated throughout by means of line (*camera lucida*) drawings and half-tone blocks. A few English terms such as "microsporangium" are Americanised into "microsporange," but such is of no importance unless it is that it is unfortunate that the nomenclature and terms which have already seen adequate service and have now come to be universally employed should be cast aside. There is nothing that is new to the botanist in its pages, but to the American student it will prove its worth as a useful text book, while to the teacher it will come as an accurate and clear presentation of the subject.

G. C. T.

CATALOGUES RECEIVED.

MESSRS. FISHER, SON AND SIBRAY'S Gardening Manual for this year has reached our hands, and it is evident that the high standard of excellence which this firm has attained in the Midlands and throughout the country in general will be maintained during the year. Those who have had dealings with the firm will be well aware of the high quality of the seeds, and while that is maintained at its former level, an unlimited choice and variety is given to the intending buyer of vegetable and flower seeds. The firm has a long and well established reputation behind it, and we have no hesitation in recommending it to our readers. The address is The Royal Nurseries, Handsworth, Sheffield.

An extremely useful list of flower and vegetable seeds is presented by Messrs. William Cutbush and Son, Limited, Barnet, Herts. To our readers in the South this firm will be well known by its presence at the majority of the Royal Horticultural Society's shows. The amateur will find the catalogue of great service, as it recommends certain collections of flower seeds and also vegetable seeds, and those who do not wish to have the difficulty of choosing their own sorts thus find it solved for them. The varieties are chosen on a most liberal scale.

Another useful list of vegetable and flower seeds and a reliable guide to the best varieties for 1925 is that published by Robert Sydenham, Limited, Tenby Street, Birmingham. It is a handy size, and packed with information. We strongly recommend it to all amateurs who wish to have a good show in the gardens during the coming summer.

Tottenham District Council

ORNAMENTAL GARDEN

The Council invite Tenders for the construction of a Sunken Ornamental Garden. The site is situated in Seven Sisters Road, between Manchester and Heysham Roads, and is approximately 160 feet by 120 feet.

Particulars and Form of Tender may be obtained from the Engineer of the Council, Town Hall, Tottenham, N.15, on payment of one guinea, which sum will be refunded upon the receipt of a *bona fide* Tender accompanied by documents, not later than the date prescribed below, otherwise the deposit will be forfeited.

Tenders in sealed envelopes, endorsed "Tender for Ornamental Garden," must be delivered to me not later than 12 noon on Tuesday, the 20th day of January, 1925.

The Council do not bind themselves to accept the lowest or any Tender.

REGINALD C. GRAVES,
Clerk and Solicitor of the Council.

Town Hall, Tottenham, N.15.
5th January, 1925.

MOISTURE AND PLANTING

SO much has been said, either aloud or under the breath, about the past season that there is little use recapitulating all its eccentricities. In some ways, however, it has been a most remarkable season. The actual rainfall in a few parts of the country has not been so large in bulk as in 1923, and throughout the country it has been patchy, but whatever the rain gauge may say, there is no doubt that the universal complaint is that it was the wettest rain that has ever fallen. This is, of course, caused in great measure by the number of days on which rain fell, but there is a further reason in many areas, and that is that the subsoil is not suited to carry off so much water in two consecutive wet years. Probably many old drains, which may have been hidden for years and yet have worked efficiently, have become choked and so helped to make the ground even more water logged.

It is to be hoped that some time during the next two months we may have sufficient hard weather to break up the surface, and it is advisable at present to dig and trench every available piece of ground so that as much of the surface may be exposed to the air as possible. In many gardens, where the soil is clay or heavy loam, the surface is so puddled that a thorough loosening of the soil is imperative, otherwise another wet year might do irreparable damage. Another season such as 1923 and 1924 coming on top of a water-logged surface would make aeration impossible, while the surface would be baked like a brick if a drought came with hot sunshine and drying winds. It is natural that gardens with a heavy soil and subsoil have suffered the most, while those with a light surface and gravel subsoil have actually benefited by the damp seasons of 1923 and 1924.

The plants which have undoubtedly been helped by successive rainy days are trees and shrubs; they have never had such a time in their lives. But even they can have too much of a good thing and in some cases, usually in heavy soil, they are flagging and appear thoroughly unhappy; the reason for this is that the soil in the hole was tramped in before the plant was planted, with the result that a basin was formed from which the water could not escape, with accompanying stagnation to the plant. If the plant is too big to be conveniently lifted and replanted after breaking up the soil, the remedy is to shove a crowbar deep into the ground so as to break the basin and allow drainage; this may be slow owing to the sodden condition of the ground, but is better than nothing.

It is a curious fact that many people who may be excellent gardeners often have two bad habits: one, as I say, is tramping in the earth in a hole made for planting; the other is of planting too deep. Too shallow planting is infinitely less obnoxious to almost all trees and shrubs than the opposite. A plant raises a stem in order that it may be exposed to the air and the elements and even if a small portion of this stem be covered it may disarrange its interior economy with the result that the plant shows its displeasure. There have been numerous cases of disease attacking a plant solely because it has been covered by soil above the collar. I cannot impress the error of too deep planting too strongly upon my readers, whether it be in fruit trees, ornamental trees, conifers, or shrubs. Naturally there are a few exceptions, as in the case of willows, but they only prove the rule.

It is also a mistake to plant when the ground is too moist, for the necessary tramping in of the soil around the plant puddles the earth and turns it into an impenetrable mass. In any case it should be seen that roots are carefully spread out in something approaching their original position. If the original soil was clay or heavy loam and sticks to the roots, as much of this should be removed as possible, of course taking care not to damage the roots, for travelling or transplanting has probably hardened the soil, so that it has formed a cake around the roots, which are unable to function properly and make their way through the hard mass.

Planting is a serious business, if your plants are to thrive from the moment they are planted, and in wet seasons a difficult one. It is not merely a question of digging a hole and shoving in the plant. Soil and general conditions must be examined with a critical eye. Successful planting requires thought and patience, but this is not done in vain.

GLOXINIAS

THERE ARE FEW FLOWERS WHICH POSSESS SUCH BRILLIANT COLOURING AS THE GLOXINIA. AS THE AUTHOR POINTS OUT IT SHARES THIS WITH THE BEGONIA. THESE TWO GENERA HAVE THE PECULIARITY THAT THEIR COLOURS ARE NEVER SO STARTLING AS TO CLASH WITH OTHER FLOWERS IN THE GREENHOUSE.

HAD one to name the most brilliant flower of the indoor garden, the voting would probably be fairly even between the gloxinia and the begonia. It is the former, however, that really deserves the highest place, not because of its superiority, but because of its wider range. Grand as the begonia is we have but to think of those gorgeously rich velvety blues and purples; those vivid scarlets and crimsons, running into shades so deep as to be nearly black; those wonderful sunset pinks and mauves that are so prominent among the gloxinias—to realise that they are indeed the regal queens of the greenhouse.

Considering their marvellous wealth of beauty and variety, few plants are easier to grow, and this is especially true of that aspect with which we are concerned to-day—raising from seed. Not only is this a simple matter, but he who sows now is sure of an early reward, for, about six months from the date of sowing, good plants, well furnished with bloom, result. Another splendid feature is the high quality of the flowers, for one finds very few that need be discarded as not up to standard.

One matter is absolutely essential to success, and that is a steady and sufficient temperature—60° to 70° being the minimum under which culture is possible. The seeds are very small, and thus precautions have to be taken to prevent their becoming too deeply covered by soil both before and during the process of germination. Prepare a clean seed pan by well crocking, first with one large crock over the drainage hole and then a layer of smaller pieces over this. Drainage is of prime importance, and particular care should be given to this point. A compost, consisting mainly of fibrous loam with a very moderate amount of leaf-mould and peat, should be thoroughly mixed together, with sufficient coarse sand to make the whole feel gritty. This should be sifted so as to divide it into two heaps. Place a thick layer of the coarser part over the drainage and then surface to within ½in. of the rim with the finest earth. Make this level and press moderately firm, then water lightly with a fine-rosed can and set aside for an hour to drain before sowing. The seed is more evenly distributed by mixing with an equal bulk of the finest sand, and the importance of even and thin distribution is only recognised when the time comes to prick off the young seedlings. No covering of soil of any kind should be attempted; simply sprinkle the seeds and sand on the surface and then cover the pan with a sheet of brown paper and a pane of glass.

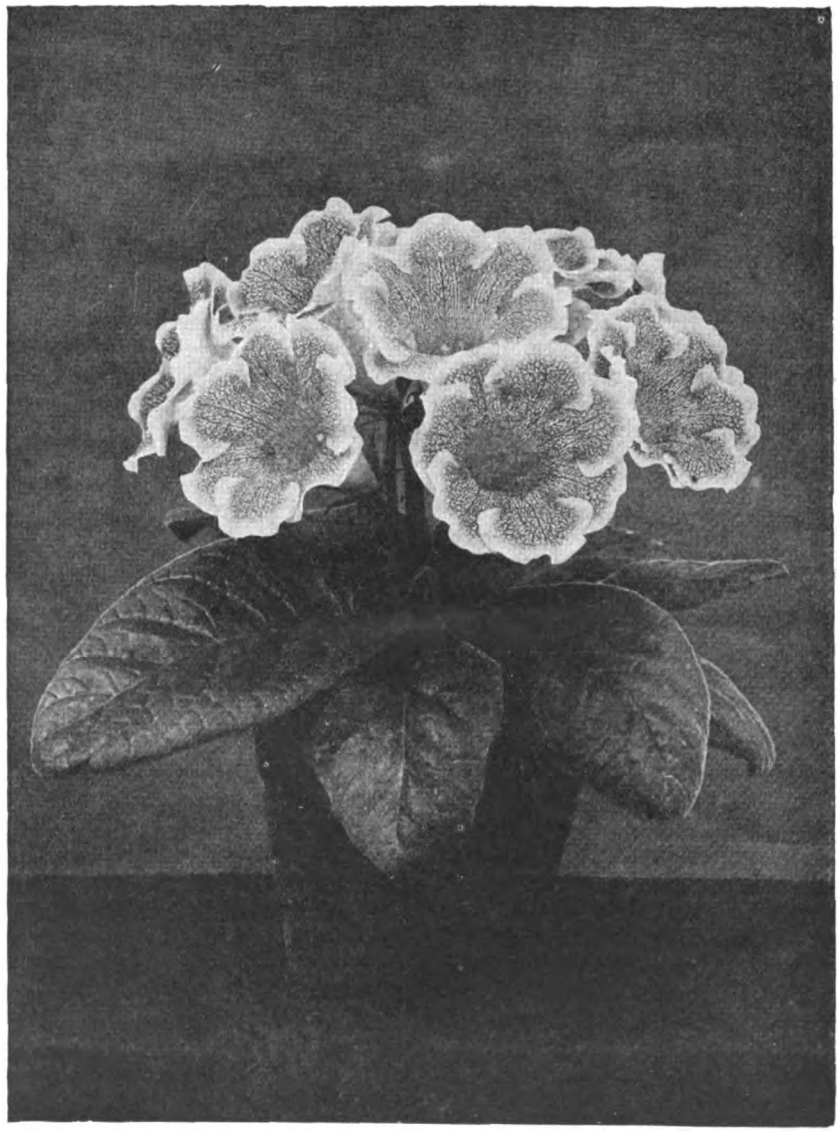

Photo. Blackmore & Langdon.

GIANT BLOOMS OF GLOXINIAS. THESE ARE ORDINARY PLANTS AND ARE NOT RAISED FOR EXHIBITION PURPOSES.

Stand this pan in a steady temperature of 65° to 75° and see that the soil is kept evenly damp without being swamped. It is most important that the soil should never become dry, for the tiny seeds produce equally tiny plantlets, and these, if dry, even for an hour, will be shrivelled up. Of course, it is impracticable to apply water in the usual way, and the best method is partly to immerse the pan in tepid water until this has made its way upwards through the soil to the surface and so thoroughly moisten the whole. Keep the brown paper and glass over the pan until the seeds have germinated, then dispense with the paper so as to admit light. Care must be taken that bright sunlight does not shine directly upon them; but, bar this, full light is a great asset in obtaining healthy seedlings. A steady temperature, regular waterings with tepid water and the admission of air by gradually withdrawing the pane of glass encourage good growth.

It is better not to disturb the small plantlets until they have attained some size; but if, here and there, a few seeds have been dropped too thickly, lift them on the point of a sharpened stick and transplant to further pans, rather than allow them to crowd each other. Before any of the leaves touch each other, deal with the whole batch in the same way, carefully lifting the plants with as little damage to the roots as possible, and transfer them to other pans, where the leaves

Digitized by Google

will have more space for expansion. For a few days after this removal, the plants should be kept rather close so that they will not suffer a check. As soon as they begin to grow again, however, expose to the ordinary atmosphere of the house, but watch that the temperature does not fall below that previously advised. When the plants have again made sufficient progress and the leaves nearly touch, they are ready for small pots. This time, the young plants will be quite easy to handle, and no difficulty will be experienced in lifting them with a good ball of soil round the roots. Similar soil to that advised above should be used, save that it need not be sifted, although the leaf-soil should be well broken up and the peat well pulled apart. Place the soil inside the house where the plants are growing, two or three days before it is required for use, and see that it is pleasantly moist. Needless to say, perfectly clean pots must be used, and quite as much care is necessary in arranging the drainage as was the case when filling the pans for the reception of the seeds.

Potting is done in a special way, *i.e.*, the surface of the soil should be made convex so that the leaves "sit" upon a raised mound, and thus, when watering is done, it will drain away to the sides and not lead to damping off at the centre. The soil should be made firm but not too hard, as the gloxinia likes a spongy soil. Return the plants to the shelves, watch the temperature and see that the atmosphere is kept moist. The fine velvety leaves are a great asset in the good appearance of the plants, and full development of these should be encouraged by maintaining plenty of moisture in the atmosphere. The leaves themselves should never be wetted, either by damping or syringing, as they are very liable to decay, especially at the tips, where moisture is most likely to lodge. The best conditions of all are obtained by standing the plants on a closed staging covered by fine shingle or coke breeze, as this can be regularly watered and thus provides an evenly damp atmosphere. Do not make the mistake of crowding your plants: remember that, by the end of the summer, each plant will occupy a 6in. or 7in. pot, over the edge of which the large leaves curve nearly to the base, and therefore sufficient space must be allowed for these and for plenty of air to circulate between them. While the air must not be allowed to become stuffy, anything in the nature of a draught should be strictly avoided, for its chilling as well as its drying effects.

Under genial conditions, rapid growth will be observable, and immediately the first pots are well filled by roots the plants should be transferred to a larger size. Be sure, as these larger pots are reached, that a sufficient depth of drainage is employed, for gloxinias do not root very deeply, and a large body of soil that is not occupied by roots is liable quickly to become sour. Whenever water is applied to the roots, be sure and pour it well to the side of the pot, so that it does not lodge in the crown of the plant, and, at each successive potting, be careful that the crown is not buried beneath the soil. When the first flowers begin to expand, feeding with liquid manures should be commenced and, provided these are used weak and varied as much as possible, applications may be made once a week, taking care, however, that the whole of the soil is first thoroughly moistened. The best way is to well water your plants with plain water first, then pause while this drains through, and then go round the plants again and apply a small amount of manure water to each.

Another aspect of culture (that should be attended to now) is starting a number of the best of the old tubers, with a view to propagation by means of the leaves. It is necessary to get these into vigorous growth as early as possible, with a view to obtaining large leaves with a thick midrib. The earlier these can be taken off and rooted, the larger and stronger the tubers you will be able to obtain by the autumn, and every week they can be advanced is clear gain. This method of propagation is simplicity itself. When the leaves have reached maturity, detach them from the parent plant and nick the midrib in two or three places. In order to economise room the outside edge of the leaf may be trimmed down to a considerable amount, leaving, however, about an inch of the green leaf on either side of the midrib. Fill a sufficient number of pots with soil, as used for potting, and surface with ¼in. of clean sand. The leaves must now be laid upon the surface of this, so that, from the nicked places, roots may form and make their way into the soil.

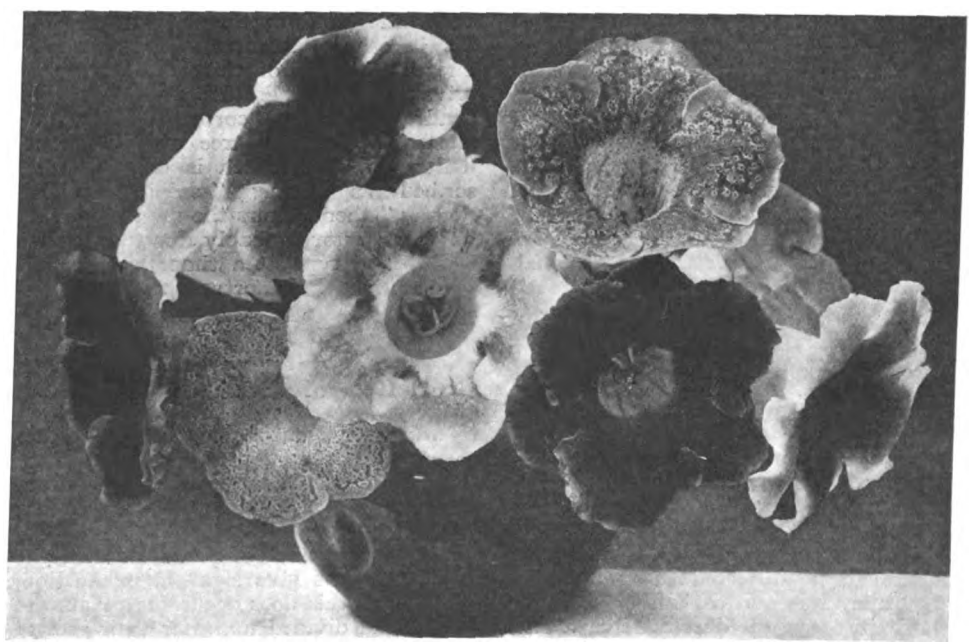

Photo. Sutton & Sons.

THE MOST EXOTIC LOOKING OF ALL GREENHOUSE PLANTS. TYPICAL BLOOMS OF GLOXINIAS.

There are several methods by which the cut surfaces may be kept in contact with the sand, but the one that we have found most satisfactory is using small bent wire pegs pushed through the leaf surface and circling (or rather, half-circling) the midrib. This makes everything absolutely secure and prevents the possibility of their moving during the process of rooting. After each leaf has been firmly secured, the pots containing the cuttings should be covered by a pane of glass or placed in a propagating frame, where the temperature should not fall lower than 65° Fahr. It is most important to keep the atmosphere moist, but not to over-water the soil. This should be kept evenly damp without being wet, otherwise the leaves will certainly begin to rot and decay. Within a few weeks, roots will have pushed out and the cut surface of the midrib begins to form a new tuber. This process is followed by the appearance of leaves and the decay of the original leaf from which they sprang. At this stage, the new plantlets should be lifted from the pots in which they were rooted, potted off and treated as seedlings.

RHODODENDRON HYLOCALLIS

THE question is often asked, What is R. hylocallis, or alternatively, what is Farrer's No. 813? In going through Farrer's specimens I find that he suggested the name "hylocallis" for his rhododendron No. 812. This (Farrer's hylocallis) is named by Sir I. B. Balfour, R. tanastylum (Balf. f. et Ward). The type of R. tanastylum (Ward 1566) was gathered by Ward (1914) at Hpimaw, East Upper Burma. It is typically a member of the Irroratum series and is described by Ward as "a medium sized scraggy bush or more generally thin tree of 20ft. Flowers crimson." Farrer's 812, gathered (1919) above Hpimaw at 8,000ft., is described on the field ticket as "a loose spindly tree of 20 to 30 ft. Flowers a rich crimson scarlet." There is no doubt it is the same as Ward's 1566.

Farrer's 813 is a very different plant. It is a member of the R. sulphureum phylum of the Boothii series, gathered also in 1919 at 8,000ft. in the upper jungle above Hpimaw. Farrer describes it as an "epiphyte on tree trunks." "Scentless flowers of light sulphur yellow." For this plant Farrer suggested the provisional name of R. chrysochloron, but a year later he gathered on the Chawchi Pass at 10,500ft. a plant of field No. 1550. This, he says, equals his No. 813, and adds the comment, "as before usually epiphytic in masses on moss on old Abies in the high alpine zone." Now, Farrer's 1550 is the second type number of R. cerinum (Balf. f. et Forrest), the first type number being Forrest's No. 17592 from the Shweli-Salween divide, collected in 1918. I think there is very little doubt that Farrer is right and that his Rhododendron No. 813 and No. 1550 are the same thing.

Thus we have: Farrer's 812 (1919) provisionally named by him R. hylocallis, but matched by Balfour with Ward's 1566 (1914), R. tanastylum. Farrer 813 (1919, provisionally named by him R. chrysochloron, which equals Farrer 1550 (1920), R. cerinum, the other type number of which is Forrest's 17592 (1918).

Farrer's 812 and 813 are both in cultivation and to the seedling plants under the No. 813 the name hylocallis has in many instances been attached. The explanation of this is that in the privately printed list of Farrer's Rhododendrons, 812 is correctly given as R. tanastylum, "a tree of 25ft.," but under No. 813, which is correctly described as having "sulphur yellow flowers," there occurs the name R. hylocallis, an error probably due to a transposition of type at a time the list was being printed. Unfortunately, this error is repeated in Mr. Wilding's useful list of "Rhododendron Names" and in Mr. Millais' "Rhododendrons, Second Series."

Mr. Farrer writes so enthusiastically of R. tanastylum (*Gard. Chron.*, April, 1921, page 162) that one awaits the flowering of his 812 and the Forrestian numbers of this species with much interest; the more so as he optimistically states that he does not think "the fear overshadowing the usefulness" as a garden plant of "the lovely and fragrant R. McKenzieanum which is in full tenderness of shoot in mid-April" need be felt regarding "its contemporary R. tanastylum, for this is a plant of higher elevations and is still in copious bloom in mid-May." Nevertheless, the behaviour of young plants in north and east Britain at any rate leads one to suspect that this optimism was misplaced. It is, perhaps, too soon to be sure of this.

In conclusion, I wish to note an error in the article in the *Gardeners' Chronicle* referred to above. There R. tanastylum is given as F. 815. This is apparently a misprint for F. 812. Farrer's 815 is R. æmulorum. Plants under this number are in cultivation and, as far as one can possibly tell from foliage of young plants, they are true to number and name.

HEPATICA UNDER PERGOLA AT GRAVETYE

BEAUTIFUL spring flowers from the mountains, copses and woodlands of North America and some parts of Europe—though not of Britain—are these harbingers of spring.

With the arrival of February a movement can be observed in their lily of the valley like crowns, and by the time the early days of March arrive a little colour may be observed, and by the end of that month the zenith of their beauty has been reached.

The hepatica should never be planted in full sunshine, for it loves a loose, moist, leafy soil such as the decayed matter found at the base of old hedgerows or ditches and shade which is afforded by summer leafing trees, evergreens of any description being too dense and the soil about them too dry. Under such conditions it is astonishing how well these plants thrive, and the gorgeous effects produced by their profusion of bloom is amazing. The favourite haunt of Hepatica triloba—here shown—appears to be the southern oak woods of the Alps, where it is protected from the glare of the sun. It is also one of the mountain plants that creep nearest the Mediterranean wherever the hills approach the sea.

The plants here shown are growing at the foot of an easterly wall and beneath a wistaria-covered pergola, and, as will be seen, little flat stones are placed between the plants which serve to keep them cool and keep down weeds. After the flowers are past, these stones are entirely hidden by the leaves.

This treatment appears to suit the plants admirably, for hundreds of flowers, striking in effect, appear annually from a single plant and form cushions of intense blue.

After a number of years some of the largest plants give signs of exhaustion, and when this does occur the plants are lifted and divided up, after their growth is completed, and fresh plantations made, using a good open and friable soil.

On cold soils the hepatica loses its leaves in winter, but these are to a considerable extent retained in well drained positions.

Personally, I like to see the leaves die off, as the plant is then at rest and flowers better for it; and while in this dormant state advantage should be taken of applying a top-dressing of leafy soil, as the plants revel in it.

Raising from seed is very interesting, for one is never quite sure of the result, and the expectancy of new or varied colour shades, and perhaps something of special note, makes seed raising a fascinating hobby.

The seed should be sown as soon as ripe in boxes of sandy soil, placed in a cool, shaded frame, or even in the open with a slate over it to prevent evaporation and provide shade.

Some of the seeds germinate very quicky and others do not appear until the following spring; these, when large enough to handle should be pricked off into boxes of sandy and leafy soil and grown on in a cool temperature.

ANEMONE HEPATICA TRILOBA is, perhaps, the best known of this interesting genus, and there are several varieties—some with double flowers; but, to me, the beautiful blue flowers, with their protruding (white) anthers, place the type plant in front of them all.

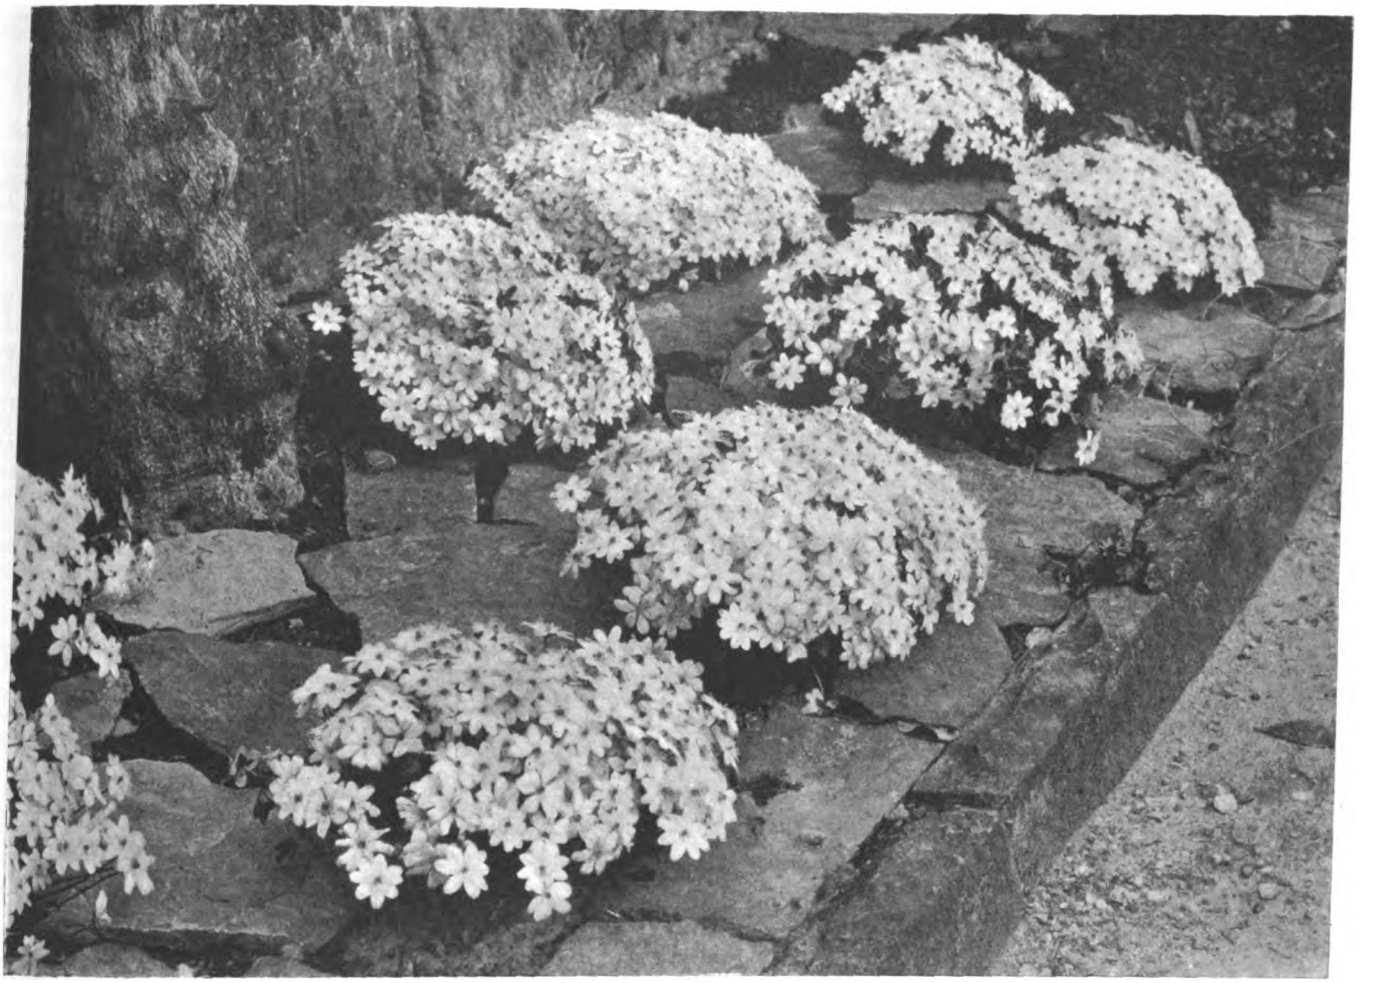
A mass of well grown plants of this free-flowering species is a magnificent sight. Hundreds of these plants are grown here, and their amazing beauty each year as this sea of blue arises from the naked earth—and this when most plants are still at rest—is one of surpassing charm.

A. H. TRILOBA ALBA is a pretty plant with reddish anthers which are in pleasing contrast to the whiteness of the petals. A double white variety is also occasionally grown and is quite a desirable plant, though rather scarce.

A. H. TRILOBA CŒRULEA is a distinct rich blue variety, and a double form of this has very attractive deep blue flowers.

A. H. TRILOBA RUBRA, with single rose-pink flowers, must be included in every collection; also its double form, their distinct colours being conspicuously effective when grouped among quantities of the blue shades. I have, however, found these less robust than the other kinds mentioned. Growing here, and in addition to those given above, there is the handsome large-flowered species, A. H. angulosa, from the hills of Transylvania, and its lovely varieties, including the white one.

Digitized by Google



WELL GROWN CUSHIONS OF ANEMONE HEPATICA TRILOBA WITH HUNDREDS OF FLOWERS OF INTENSE BLUE.

A. H. TRILOBA ACUTIFOLIA, from the Central United States.

A. H. TRILOBA BARLOWI, a distinct and lovely blue flower.

A. H. SESSILATA, in which the calyx protrudes beyond the flowers; and

A. H. VARIABILIS, with curiously mottled leaves.

The other species from Hungary, known as angulosa and already referred to, grows in tufts like other hepaticas, with large blue, white or reddish flowers. Among its lovely varieties are such as alba, with pure white flowers; rosea, a rose-coloured form; lilacina, with lilac-coloured flowers. All these forms are excellent when grown in the wild border for very early spring b'oom. E. MARKHAM.

SOME PROMISING FOREIGN ROSES OF 1922

MOST of the new foreign roses only reach us a year after the British varieties are available, and it is therefore a matter of some difficulty to arrive at a definite opinion on their merits or faults after the results of only one year's growth.

The 1922 new foreigners do not promise very much on the whole. So far there is no suggestion of any characteristics or qualities to equal the British varieties of that year, such as Betty Uprichard, Lady Inchiquin, Admiration, Lord Charlemont, Sovereign and Mabel Morse.

A few of them however, which have come under our special notice as showing signs of promise, we will proceed to refer to and describe in detail.

IDEAL, *Dwarf Poly*. (Jan Spek).—This is a sport of Edith Cavell, which it somewhat resembles. The colour is dark scarlet, and blooms are full. Growth about 12ins. high, and its foliage is clean, small and neat.

ELVIRA ARAMAYO, *Pernetiana* (P. J. Looymans).—Very bright and unique India red colour. The buds are pretty, but the blooms are rather shapeless and rough. It was shown in the decorative classes at Croydon by Messrs. D. Prior and Son, and the colour was startling but there was hardly a decent-shaped bloom. Height about 24ins., and foliage fair. Massed in a bed, it should make a wonderful splash of bright colour.

EMILE CHARLES, *Pernetiana* (P. Bernaix).—A sport of Mme. Edouard Herriot, which it resembles exactly so far as growth is concerned, and that unfortunate habit of hanging its head. The colour, however, is much paler, being almost a light coral pink. Height about 24ins. It bloomed well in autumn.

GENERAL SMUTS, *H.T.* (G. A. van Rossem).—Origin: General McArthur × Mme. Edouard Herriot. Very bright deep coral red. Semi-double blooms. Tall and erect growth about 30ins., resembling General McArthur.

SUBSTITUT JACQUES CHAPEL, *H.T.* P. (Bernaix).—Origin: Mme. Mélanie Soupert × Lyon. Large blooms of peach-blossom colour, cupped shape, and very fragrant. Very strong grower, but the weight of blooms bends the trusses over. Height 24ins., and gives good autumn blooms. A promising bedding rose.

SOUVENIR DE F. BOHE, *H.T.* (C. Chambard).—A seedling of Willowmere, growth being almost identical, but the blooms are a pretty pale coppery pink. It is catalogued as an H.T., but should surely rank with its foster-parent as a Pernetiana.

GOOILAND, *H.T.* (G. A. van Rossem).—Origin: Sunburst × Red Letter Day. Bright pink colour with reverse of petals darker, reminding one of Mrs. E. G. Hill. Slightly scented. Height about 30ins. Continuous bloomer till late in the autumn.

These are our first impressions on seven varieties out of about fifty varieties on trial, under conditions which, as this last summer, gave the poorest opportunity for the establishment of their true merit. We shall, therefore, be able to write at greater length and with more confidence after the results of careful observation during a second year's growth, under weather conditions which approach more closely to the ideal.

HERBERT L. WETTERN.

PRUNING FRUIT TREES

PRUNING HAS PROBABLY GIVEN RISE TO MORE LITERATURE THAN ANY OTHER BRANCH OF HORTICULTURE, BUT AS THE WRITER POINTS OUT PRACTICE IS THE ONLY SURE TEACHER.

PRUNING is one of the most interesting and important, yet difficult, of all operations connected with fruit culture. It is an operation which cannot be satisfactorily learned theoretically. Only practical experience will enable anyone to solve the many problems which are sure to arise.

There are certain principles upon which the art of pruning is based, such as why to prune and when to prune, which are readily learned. Exactly how to prune is not so easily grasped. So many factors play a part in how it should be done, that it is impossible to lay down any hard and fast rules on the subject. Factors involved are such as soil conditions, which may vary so much as to cause two trees of the same variety to grow quite differently in one place from what they do in another. The root system, too, plays an important part, and the eventual pruning of many fruit trees can be largely gauged by knowing the stock on which the tree is worked, and training the tree to the shape suitable for the root system.

Manuring, too, will have some bearing on the question; for instance, much nitrogenous manure together with hard pruning would have a tendency to produce a lot of growth at the expense of fruit buds. On the other hand, phosphates and potash with a minimum of pruning would tend to excessive fruit bud formation.

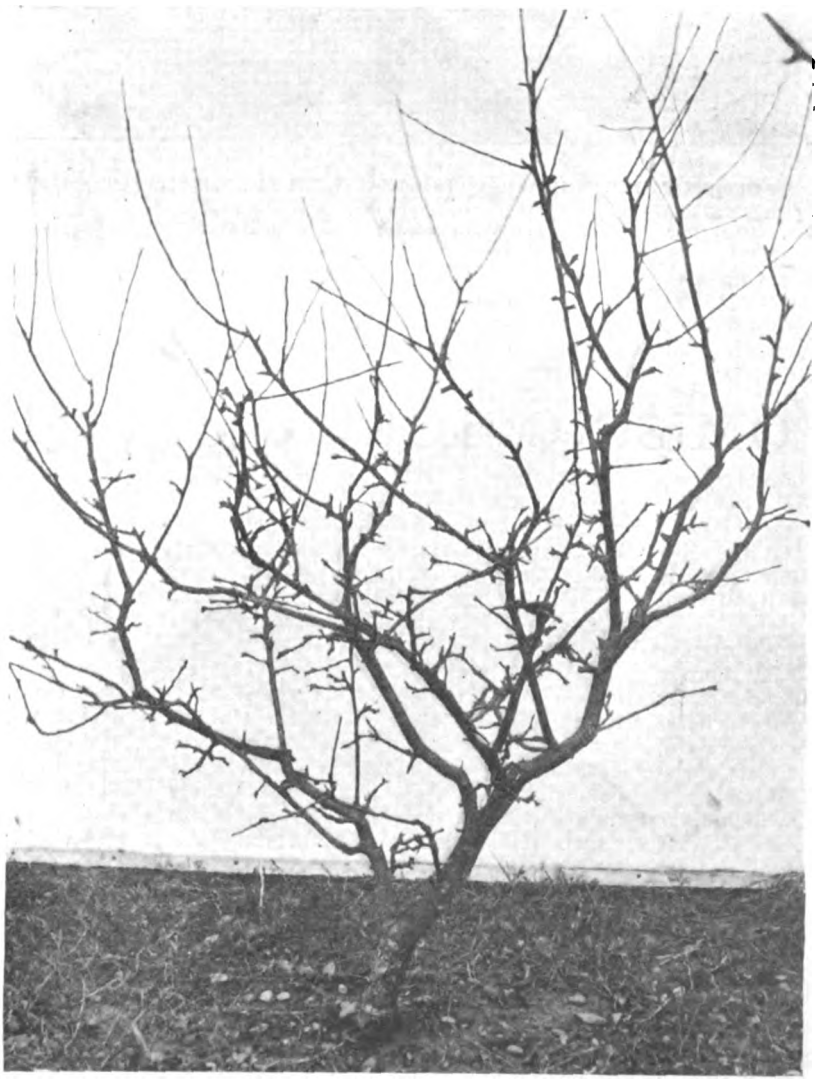
Many varieties, too, differ in their habit of growth, and naturally shy-bearing varieties have generally to be treated differently from an acknowledged regular cropper. In addition to these largely controlled factors, there has to be considered the uncontrolled one of climatic conditions. This may be such as to militate against the setting of the fruit or ripening of the buds, with the result that a tree which has not to undergo the strain of carrying a crop will, in most cases, tend towards the making of wood. It is, in fact, necessary to study each tree individually before touching it with a knife. Every pruner should, therefore, use judgment or, to put it plainly, common-sense in pruning each tree.

Regrettable as it is to make the statement, it is nevertheless true that very large numbers of fruit trees are almost ruined during the three or four years following their purchase from a nursery. Of course, this does not apply to the garden where a trained man is responsible, but rather in the amateur's garden or where a man in charge is more or less in the nature of a handyman and does not profess to be skilled in fruit culture.

Oftentimes the owner is keenly interested in his fruit trees, and is glad to get any hints on the way things should be done. Strangely enough, however faulty the pruning may have been heretofore, the amateur owner seems to imagine that, once the trees have been pruned properly, fruit will automatically follow the next season. As, however, the trees often have to be reshaped after years of wasted energy, it must obviously take some time before a full crop can be expected.

It is the first few years of the tree's life after leaving the nursery which are so important. If skilled attention were then given to continue the training to whatever shape it was intended to be, whether half or full standard, bush, pyramid, espalier or cordon, the resultant pruning would be much simplified. A young tree is usually cut rather hard for the first few years; the object is to aim at producing wood and to train the tree according to the desired shape with regularly formed branches, and to produce a well balanced tree. Once it has got to bearing age, though, the training will be continued in a modified manner until the tree is fully developed, the future pruning will be such as to assist the tree in maintaining a perfect balance between sufficient growth and fruit buds.

Briefly to deal with the training and pruning of young trees: In the case of the cordon, the length should be built up gradually, and the leader pruned back each year according to its strength, usually from one to two feet, until the required height is reached. The lateral or side growths should be summer pruned, usually in July for apples, and a little earlier, according to the season, for pears, plums and cherries (sweet) to six or eight leaves. At the winter pruning these growths will be cut back to two or three buds and induced to form fruiting spurs. The espalier, which has usually two or three pairs of horizontal branches and a leader when bought, has to be strictly attended to until the required number of tiers—usually five or six—are made. The space between each tier should be about twelve to fifteen inches.



A BUSH APPLE UNPRUNED.

The central leader must be allowed to grow each year and tied to keep it vertical, and at winter pruning cut back to a good bud to continue the leader. Two branches for training right and left to form the next tier should be encouraged, and tied down in position. These horizontal branches will be required to be cut back at each winter pruning in the same way as the cordon, until the allotted space is filled, and the same attention paid to side or lateral growths for making fruit spurs.

As distinct from the espalier, which usually arrives from the nursery perfectly formed, the bush-shaped tree generally requires a little shaping.

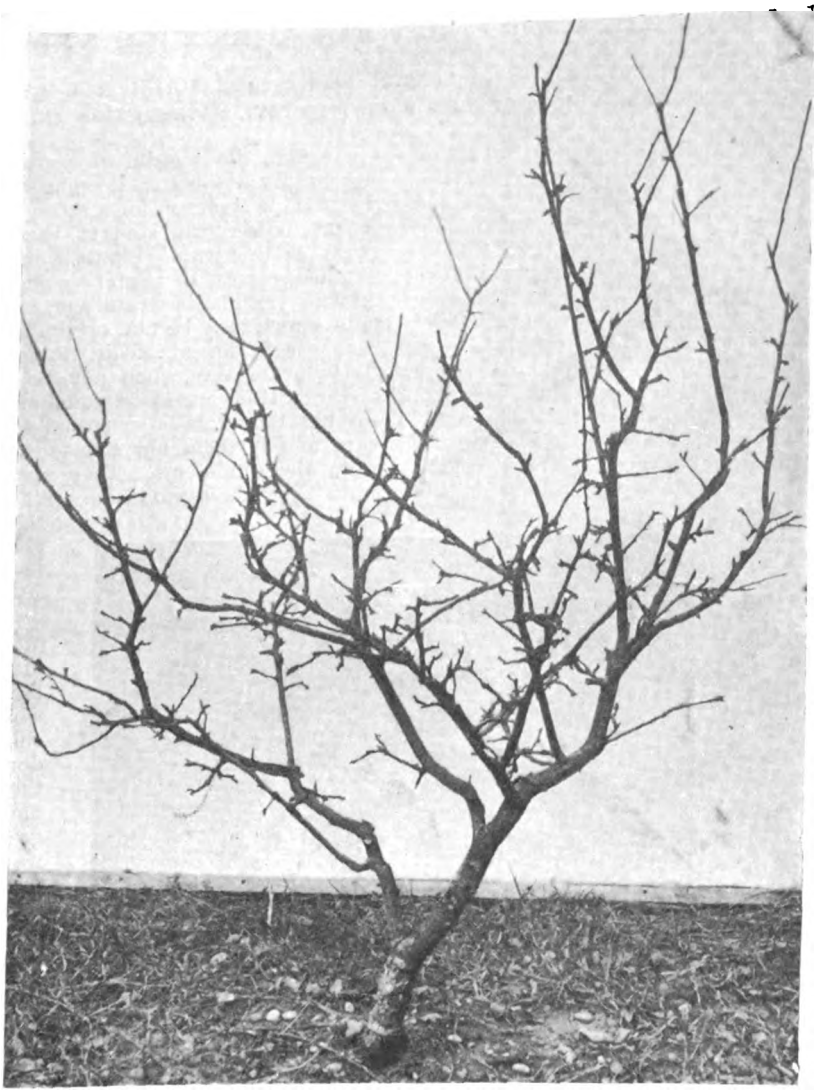
The best form for the bush is one with six

Digitized by Google

equally placed branches making an open centre, with a stem or leg at least a foot from the soil. The six branches may need some guidance to induce them to grow just where wanted. Also to obtain equality of vigour in these six cordon-like branches, it may be necessary to encourage or retard a branch by raising or bending it, thus directing the flow of sap to assist to that end. The lateral growths and extension of leaders will be treated as advised for cordons.

The pyramid is seldom grown commercially, but is in general use in private gardens, especially for pears. This type of tree differs from the bush by having a central stem from which branches are encouraged to emanate at regular intervals. These and the leader are gradually built up by shortening back during winter, according to their strength, and treating laterals as advised for other forms.

The standard is best formed with six main branches. This will ensure a good open centre, so necessary for the future well being of the tree. Should the tree arrive from the nursery with a head of three branches, these should be cut back to about a foot from their bases and two growths encouraged from each. As the tree develops, sub-mains will be allowed to grow in sufficient numbers to fill the spaces, but never to such an extent as to cause crowding.



THE SAME TREE AS OPPOSITE, BUT PRUNED.

The debatable point as to whether a tree should be pruned or not pruned the first year or season of planting is best, again, treated with judgment. The time of planting and the root system should be the guide. If planted early in the autumn and the roots are in good condition, pruning is best done in the ordinary way. If planted late in winter or early spring the tree has lost the start of the early-planted tree by about 25 per cent., and is perhaps best not pruned. If, however, watering and mulching could be attended to during summer, and even late spring if necessary, the chances are that time would be gained by pruning at planting time if the roots are in good order, instead of waiting till the following winter.

Once a tree has got to bearing age and size it should go on annually increasing in size, and proportionately increasing its weight of crop until the maximum development is reached. During this time the trained tree will require to be annually pruned by shortening the leaders according to their vigour, and to prune the lateral growth and spurs in such a way as to maintain a perfect balance between the production of wood growth and fruit buds.

Winter pruning can be done at any time from the fall of leaf till early spring. Pruning at this time, when the tree is in a dormant state, tends to the production of wood. When a tree is making too much growth and not bearing much fruit it is a sign that the balance between the roots and the branches has been upset by too much pruning.

Climatic or other conditions which prevented fruiting may have been conducive to this undesirable condition, and the tree relieved of the strain of carrying a crop has spent its energies in making growth. In such a case, to continue orthodox spur pruning would not improve matters. The pruner must then resort to other means to restore the balance and induce the tree to make fruit buds. Often the advice is to root prune to help remedy this excess of wood formation, but this should not be done unless other means fail. Root-pruning is better done before the trees come into bearing.

Young trees which show signs of excessive vigour should be lifted carefully, any strong roots pruned back and the tree replanted. This should be done, when possible, in early autumn. Root-pruning is almost certain to be necessary with young plum and cherry trees, and probably so with apples and pears. But other means should first be tried to bring the over-vigorous tree into a productive state, *i.e.*, instead of pruning back the lateral growths to two or three buds, which is the usual practice, some of the more vigorous should be left their entire length, to serve as a kind of exhaust valve for excess of sap. Others may be shortened half their length. The medium size growths should be spurred back to two or three buds, and the weak ones cut out entirely. During the following growing season less growth will be made, and the wood buds on the vigorous shoots will probably be transformed into fruit buds.

When these extension growths have fruited, they may be cut out. In the meantime, others, in lesser numbers, should be left each season. This method of pruning invariably tends to restore the balance, and by such means I have seen trees, which were a thicket of growths, restored to perfectly balanced trees carrying good crops of fruit.

The other side of the question is too little growth and an excess of fruit buds. To re-adjust this, harder pruning should be the aim, with, possibly, attention to other governing factors. The pruning of the well balanced tree is an easy matter, other factors being favourable.

Standard trees, whether they be apples, pears, plums or cherries, after the heads are completely formed, require very little pruning. What little there is to do is regarded more in the nature of thinning out branches annually. This should be done sufficiently, to prevent any danger of crowding, so that full sunlight can reach all parts of the tree. The cutting of plums and cherries, especially the latter, should be avoided as far as possible, or gumming may set in and cause loss of branches.

It is scarcely necessary to mention that all diseased and dead wood should be removed and burnt. Any signs of canker should be attended to by cleanly cutting out the injured part. As each tree is completed all such places and any cut surfaces above ½in. in diameter should be painted over, either with white lead paint or coal tar. A sharp knife should always be used, and clean cuts will generally heal quickly. A. J. COBB.

PRIMULAS for the CONSERVATORY & GREENHOUSE

THESE CHARMING SPRING FLOWERING AND COOL SEASON PLANTS ARE SUITED FOR ALMOST ALL CONDITIONS, AND IN THIS ARTICLE THOSE SPECIES WHICH WILL BE FOUND TO GIVE SATISFACTION INDOORS ARE DEALT WITH

PRIMULAS in quite a number of species and varieties are very popular and useful for greenhouse and conservatory decoration, and by sowing at different periods the greenhouse is seldom without some representative of the genus.

Primula sinensis (Chinese primrose) in its many varieties is very popular, and deservedly so when one considers the wide range of varietal forms, which includes so many colours, and most of them good pure colours. Another important point is the fact that all the varieties offered for sale come true from seed. P. sinensis was first introduced from China in 1820, and is described and figured in the *Botanical Register*, 1821, t. 539, as P. prænitens. It is also figured in the *Botanical Magazine*, 1825, t. 2564, this later figure very much resembling the P. sinensis stellata forms of to-day. Primula sinensis has never been found wild, but was a cultivated plant in China when first introduced to this country. It has never been crossed with any other species, and the many beautiful varieties of to-day have been obtained by careful selection, and cross-breeding between the several varieties. P. sinensis may be separated into several sections, viz., the smaller-flowered single varieties, which includes a set of fern-leaved varieties, and a set of doubles; there is also a set of so-called giant forms, and lastly the stellata varieties, with their graceful free-flowering habit which makes them so useful and popular for decorative work. All the sections include a wide range of colours, varying from pure white, light and dark blue, pink, salmon-pink, red, scarlet and crimson. Some of the varieties also have fine dark foliage. One of the newest varieties, Etna, has almost black foliage with fiery crimson-coloured flowers. This fine variety, which was distributed by Messrs. Sutton and Sons, is interesting because it was bred on Mendelian lines at the John Innes Horticultural Institution, Merton.

A GOOD VARIETY OF THE STELLATA SECTION OF PRIMULA SINENSIS.

Seed for general purposes should be sown during May and June in a warm greenhouse, the compost consisting of equal parts of good mellow loam and leaf-soil, with the addition of some silver sand. As the seed is always irregular in germinating, it is very important that it be sown thinly; this allows of the more forward plants being removed without disturbing the more backward ones. The seed pans should be kept shaded until germination takes place; during the earlier stages a temperature of 50° to 65° Fahr. is most suitable, avoiding draughts and direct exposure to sun. When fit to handle, the young seedlings may be pricked off into pans or into 48-sized pots. When large enough the young plants should be placed in thumb pots, afterwards shifting them into larger pots as they require it, until they are in 5in. pots, in which they should be flowered, taking care not to re-pot them until they are well rooted. The compost for the final potting should consist of about four parts good medium loam, two parts well decayed leaf-soil, with one part old mortar rubble or sand. Water should be carefully afforded at all times, and at no time must there be any attempt at coddling. From July up to the middle of September they are best grown in cold frames or low airy pits, affording them ample ventilation on all favourable occasions, and shading them during bright sunshine.

About the middle of September they should be placed in a bright airy house, keeping them well up to the roof glass. By growing them on for a second year fine large specimens can be produced: the stellata varieties are specially fine when grown in this way. Plants from a June sowing may be used for this purpose, or a later sowing may be made during August, growing the plants steadily on until they are in their flowering pots, which may be 6in. or 7in. in size. If the older plants are used they can stand in their flowering pots—5ins.—until the following May, when they should be turned out and have some of the bottom leaves trimmed off. The balls may be reduced so that they can be returned to the same sized pots, taking care to pot them low down, as fresh roots will be produced from the old stems. They should be kept close and moist until they are established. When well rooted they should be shifted into 7in. pots, afterwards giving them plenty of air. and treating them in every respect as advised for the younger plants.

At one time there was a set of plants with double flowers of various colours, but, with the exception of the old double white, they have been lost to cultivation for many years. They doubled in a different way from the present-day strains. The double white is, however, still grown for market and decorative work, being very useful for making up in floral arrangements. This and all the old double varieties have to be propagated by means of cuttings or division.

During spring and early summer the shoots should be severed from the parent plant and inserted singly in small pots, standing them in a close case with slight bottom heat; or the bottom leaves of the old plants should be trimmed off, and they should then be mounded up with leaf-soil and sand. When roots are emitted the plants should be severed and potted up separately into small pots. Their after cultivation is the same as that accorded the seedling plants, except that this variety enjoys slightly closer and warmer conditions.

Primula obconica was introduced in 1879, and flowered during 1880, and during 1881 was figured in the *Botanical Magazine*, t. 6582, as P. poculiformis. For some ten or fifteen years this plant seems to have shown little variation. After variation started new forms quickly appeared, and the many fine varieties at present in cultivation have little resemblance to the original plant, with its poor washy-coloured flowers, which the writer remembers before this plant had commenced to show signs of variation. Interesting as its development is up to the present day, it is not within the writer's province to deal with that side of the question.

In common with P. sinensis, P. obconica now affords a wide range of forms and colours, varying from pure white, blue, with varying shades of pink and rose to deep crimson. The form and size of flowers also vary greatly, as well as the size of the leaves. This primula has a somewhat unenviable reputation for its poisonous character, for it causes intense irritation to some individuals when they handle it. It has been stated that the present-day race is not so poisonous, but in the writer's experience it is just as virulent as ever, and nearly every year we have cases of men who cannot handle this plant without suffering.

Digitized by Google

The successful cultivation of this primula presents few difficulties, as it succeeds under the same treatment as that advised for P. sinensis, only, on the whole, it is less exacting in its requirements than the sinensis varieties, and by making successional sowings it may be had in flower more or less all the year round. For early autumn flowering a sowing should be made during March; while for winter and spring flowering sow from May to July. Seed should be sown in a warm greenhouse, the subsequent cultivation being on the same lines as advised for P. sinensis, *i.e.*, perfectly cool treatment in cold frames or pits during the summer months. This primula is a free-rooting plant, and when it has filled its flowering pots with roots, enjoys liberal feeding.

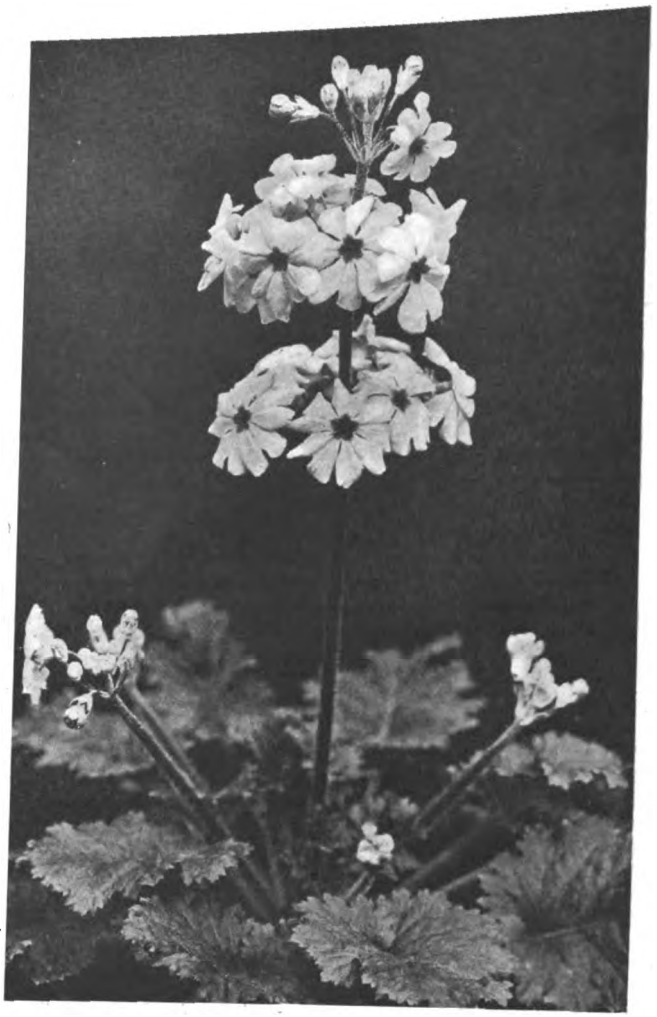
Although Primula malacoides from western China was discovered by Père Delavay in 1884, its introduction is due to Mr. G. Forrest, who collected it during 1905 and 1906. From the seed sent home to Mr. Bulley of Neston, plants were raised which flowered during 1908.

This dainty primula soon became popular, and is now grown in large quantities for decorative work. Under cultivation it soon showed signs of variation, for in 1912 white and double forms are recorded. The flowers also vary considerably in size and colour.

It succeeds perfectly under the same conditions as P. sinensis and P. obconica; indeed, the plant is nearly hardy, for during mild winters it will stand outdoors. It grows very quickly, and it is a mistake to sow it too early, at least in the immediate neighbourhood of London, for such plants get overcrowded with foliage, which is very apt to suffer from damp during the winter. Of course, this may not occur in the country, where better light conditions obtain.

Seed may be sown in a cool house or frame from May to July, according to requirements, giving it the same treatment as advised for the other species. For general work they are best flowered in 48-sized pots; on the other hand, for special decorative purposes perfect little specimens can be produced in 60-sized pots. Such plants are very useful for table decoration and for making up vases and baskets.

Although Primula verticillata was introduced from Abyssinia in 1870, it is by no means so generally grown as it deserves to be, as it is a very distinct plant with pale yellow flowers, and foliage covered with white, mealy powder. It is also interesting as being one of the parents of P. kewensis. Seed is best sown during August, or at least early in the year, as this plant is somewhat slow in its younger stages, and at least fifteen months must be allowed to produce good flowering plants in 48-sized pots; such grown on in 6in. pots for a second season really shows this primula at its best. It succeeds under the same conditions as P. sinensis or P. obconica, growing quite well in any good potting compost.



A TYPICAL MEMBER OF THE MALACOIDES SECTION.

ONE OF THE MANY VARIETIES OF PRIMULA OBCONICA

Primula floribunda is a native of the western Himalayas and was introduced in 1883, and is the other parent of P. kewensis. It has yellow flowers and grows from 4ins. to 8ins. in height, and is a pretty little plant for the small greenhouse. The flowers vary somewhat in colour and size, the variety Isabellina having creamy white flowers. Its successful cultivation presents no difficulty as it succeeds under the same conditions as the other greenhouse primulas, and excellent examples can be produced in 48-sized or 60-sized pots. If seed is sown during May the plants will flower during the following winter or spring.

Primula kewensis occurred as a chance seedling among a batch of P. floribunda at Kew in 1899. The original plant was sterile and had to be increased by division. At the present day it is almost unknown, and is scarce in cultivation, its place being taken by the seed-producing form which was sent out by Messrs. James Veitch and Sons. It was a pity this form was not given a varietal name, as it differs in many ways from the original P. kewensis, which is a much more dainty and graceful plant. But space forbids me dealing with the interesting history of this plant.

Turning to its cultivation, it presents no difficulty, as it succeeds perfectly in a cool house or cold frame during the summer months. Seed for successional batches may be sown from March to July. Good examples may be flowered in 5in. or 6in. pots.

Digitized by Google

Primula Forbesi is a dainty little primula which may be described as a miniature P. malacoides. It is useful for the small unheated greenhouse. If seed is sown during August or September the plants will flower the following spring. It succeeds perfectly in a cool house, and several plants may be placed in a 48-sized pot. J. COUTTS.

BOOKS ABOUT PLANTS.—II

GENERAL BOOKS.

THE next phase in a gardening library is that of works of reference, books which, however full of information, are not suitable for what might be called thorough reading. They are in constant use and lie on a shelf by themselves; in fact, they are the backbone of a gardening library.

There are two cyclopædias; one, which I mentioned in the first article, Nicholson's "Illustrated Gardening Dictionary," in five volumes; the other is an American publication of Macmillan's, the "Standard Cyclopædia of Horticulture," by L. H. Bailey, in six volumes. This is rather an expensive publication and is, of course, primarily intended for the guidance of horticulturists in the United States, but in the absence of a modern English encyclopædia it is of great value to gardeners throughout the British Isles,. It deals with practically everything in common cultivation in this country, but leaves out many of the new and rare plants which are not grown in the United States.

Of dictionaries in one volume the most important are "Johnson's Gardening Dictionary," published by Messrs. Routledge, and "Black's Gardening Dictionary," by E. T. Ellis and published by A. and C. Black. The former was first published many years ago, but has been brought fairly up to date; it is certainly the most handy volume in which to look up the bare details about a plant. "Black's Gardening Dictionary" is not quite so comprehensive as regards plants, but is more complete in work to be done in the garden. Both of these books are important in their way, as handy time savers. However, gardening, as a rule, is not an occupation to be hurried, and we must look to some of the general compendiums for useful information in more solid form.

For beginners—and, indeed, for everybody—as a book of reminders, the first and the best book on the general subject is "Gardening for Beginners," by E. T. Cook, published by *Country Life*. This volume deals with everything that may concern the ordinary gardener; it has run through many editions, and there is a new one in preparation which is being brought thoroughly up to date. Another work of the same kind, although written for more advanced gardeners, is "My Garden Book," by John Weathers, published last year by Longmans Green. It is a great work and gives details even of such subjects as garden accounts. Another useful book on a smaller scale is the "Real A.B.C. of Gardening," by A. J. Macself, one of the "Home Garden" books of Thornton Butterworth.

One of the greatest difficulties in the garden is the question of colour: this is a subject which causes more argument than any other. There are practically only two books on colour, "Colour Schemes for the Flower Garden," by Miss Gertrude Jekyll, a *Country Life* book which deals with the subject both from an æsthetic and a practical point of view, and "Colour Planning of the Garden," by Messrs. Tinley, Humphries and Irving, and published by Jack. This is the first book which has dared to make a comprehensive list of plants under their colours. It was a bold idea and, on the whole, has been excellently carried out, although in a few cases gardeners may not see eye to eye with some of the colour classifications of the authors; still, it is a step in the right direction, for many are the heart-burnings every year owing to mistaken colour grouping of plants.

Mention must also be made of the great book written by the founder of this paper, "The English Flower Garden," by Mr. William Robinson, issued by John Murray. It is so well known and admired that no description of it is necessary, but still, after all these years it is used as a standard work upon garden flowers. One constantly receives letters from all over the world quoting it as the authority. Two other books by Miss Jekyll, both published by Longmans Green, have an established reputation: they are "Wood and Garden," and "Home and Garden."

After this we come to a number of works dealing with wide divisions of horticulture. Of these by far the most important are "Trees and Shrubs Hardy in the British Isles," by W. J. Bean, published by John Murray, and "The English Rock Garden," by Reginald Farrer, published by Jack. Both of these are in two volumes and are the standard works on their respective subjects. Both trees and shrubs and alpines are now in the heyday of their popularity, and it will be long before these comprehensive works are superseded. For those who wish smaller volumes on the same subjects and still treating them on a broad basis, I can recommend "Alpine Plants," by A. J. Macself, published by Thornton Butterworth, a very useful book at a moderate price; and W. J. Bean's "Shrubs for Amateurs," published a few months ago by *Country Life*. Both of these are invaluable for anyone who does not intend to specialise in these subjects and yet wishes to possess a representative collection. There is another excellent book on trees and shrubs called "Gardening for the Twentieth Century," by Charles Eley, published by John Murray. Farrer wrote another smaller but charming book on the rock garden, called "Alpine and Bog Plants," issued by Edward Arnold. This is slightly out of date by now, if, indeed, any of his books can be called out of date, but is filled with useful information and advice as to the successful cultivation of alpines. For those who love the old-fashioned herbaceous border there is a most excellent book by Mrs. Philip Martineau, called "The Herbaceous Border," which is published by Williams and Norgate. It, also, is full of useful information, with lists of plants, and deals with a subject which is still the backbone of most British gardens. Another, which deals partly with herbaceous borders and partly with bedding plants, is "Annuals and Biennials," by Miss Gertrude Jekyll, and published by *Country Life*. This is, as is usual with Miss Jekyll's books, full of charm and is exceedingly useful. Another slightly smaller book is "Hardy Perennials," by A. J. Macself, published by Thornton Butterworth. This also gives excellent lists of perennials and is an admirable book on the subject.

There are a number of books on vegetables, from Mr. Robinson's big book, "The Vegetable Garden," published by John Murray, now in its third edition, which is the standard work on the subject, and, perhaps, a little too large for the ordinary gardener, down to a little *Country Life* booklet on the "Storing of Vegetables and Fruit," by Herbert Cowley. M. C. E.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

THE FIRST SHOW OF THE YEAR

THE exhibits and attendance of the initial Show of the year at the Royal Horticultural Society's Hall, Westminster, on January 12th last, does not in any way, we hope, serve as a true criterion of what lies in store for the horticultural public during 1925. The displays were small and the attendance meagre, at least during the morning. Doubtless the previous two or three days of fog had caused all interdicting exhibitors to quit, and one must not blame them. Despite the lack of a large display, there were one or two rather pleasing exhibits which served to stimulate and reinvigorate one with the promise of spring and its sunshine and flowers.

One of those was the small but excellent display of Messrs. James Carter and Co. of Iris tingitana (the Tangierian iris) in baskets. It is only within recent years that the value of this plant has been recognised as an ideal winter-flowering subject for indoor, conservatory decoration. Certainly the plants displayed by Messrs. Carter showed these merits off to distinct advantage. The plants were of good habit and growth, from 18ins. to 2ft. in height, the stems standing stiff and erect, bearing two flowers. The flowers, which are large, are of a delicate blue shade stained with yellow down the centre of the falls. It is a plant which deserves wider and more popular recognition in the future, and Messrs. Carter's exhibit should do much to kindle an interest in the plant.

IRIS TINGITANA, A SUITABLE WINTER FLOWERING SUBJECT FOR CONSERVATORY DECORATION.

A most interesting and varied collection of citrus fruits was on show from Italy through the kindness of Mr. Cecil Hanbury. To anyone who has visited Italy, the sight of the citrus groves is one long to be remembered. One can almost breathe it in the atmosphere. The main species which were on show were Citrus decumana (grape fruit) of all sizes and varieties; Citrus Aurantium, with one or two hybrids; Citrus medica and C. nobilis. These were all well grown and showed the results of careful cultivation and attention. It was quite a unique display at this time of year.

In spite of the recent weather, the carnations shown at the Hall this week were, on the whole, in remarkably good condition. Some bore evidence of the ill effects of fog on their petals. The nurseries of Messrs. C. Engelmann at Saffron Walden are in a fortunate situation where they are rarely troubled to any extent by fog. The two other firms exhibiting carnations were Messrs. Allwood Brothers and Messrs. Stuart Low and Co. Messrs. Engelmann's carnations were all good in shape and form, and the colours clear and bright. Of particular interest was a new variety called Red Laddie, which has just been introduced by this firm. The flowers were large, a pinkish red, and borne on exceedingly strong, wiry stems of exceptional length. Towards the centre of the flower the pink shaded to white. In a few months' time, when the flowers will probably be of a slightly better colour, this carnation will be a valuable asset and should become very popular. Another new variety, medium in size and in colour soft apricot striped with red, has been named Dainty. Such well known varieties as Saffron, Mrs. Hamilton Fellows, Jazz and Laddie showed that they still maintain their excellent reputation. A most useful variety for commercial purposes which was exhibited was Donald, a bright crimson with a perfect calyx and long stiff stems. Messrs. Stuart Low, who have raised many of the carnations which are now in cultivation, staged an excellent exhibit, including some of their past and new introductions. Among those raised within the last year were Sir Philip Sassoon, one of the best crimsons; Lady Hindlip, a white flecked with red; and Mauve Queen. The latter is somewhat incorrectly named, as the colour, which is attractive owing to its uncommonness, is lilac pink. The deep salmon shade of Lady Inverforth was conspicuous by reason of its intensity. For good habit of growth scarcely any surpassed the deep scarlet carnation, Lord Lambourne.

Messrs. Allwood were exhibiting perpetual, border, and their famous Allwoodii carnations. Several of their novelties were of unusual shades, Coral Glow being a new shade of terra-cotta. A brilliant scarlet flower with a perfect calyx was Edward Allwood, while White Pearl was the best white of any of the exhibits. George Allwood, a most attractive salmon shaded a deeper tone towards the centre, could not have failed to please the most critical. There were many other varieties, such as Topsy, Eileen Low, Wivelsfield Apricot, all of equal merit and whose praises have already been sung.

The neatly arranged exhibits of alpines and dwarf shrubs with fresh and dainty flowers, some peeping through the beds of peat-moss litter in which they were plunged, made one feel that spring really is on its way. Bulbous and tuberous-rooted plants in the rock garden are of great value. Those that bloom during the late autumn, winter and early spring are exceedingly welcome, and die down leaving room for the spring-flowering perennials to develop. Early bulbous irises, spring and autumn flowering crocuses, snowdrops, cyclamens, muscari, eranthis and sternbergia are all examples of this type of plant. Messrs. Waterers were exhibiting crocuses, narcissis, cyclamens and primulas, as well as other alpines and shrubs. On their stand the soft mauve of Crocus Sieberi shaded into the deeper mauve of Viola granda, which formed an excellent contrast against the tiny bright yellow of Narcissus minor. The value and effectiveness of the early irises are not fully realised, and from this exhibit their beauty could be well appreciated. Iris Sind-pers, with its pale blue flowers crested with orange, and the deep purple of Iris reticulata and Iris stylosa, are all good examples. Also I. sinda reichi and I. Histrio, shown by Messrs. Cutbush, should not be forgotten; and Scilla sibirica and Crocus versicolor, exhibited by the same firm, add to the general list of bulbous plants for the rock garden.

The chief points of interest on Messrs. Cheal's exhibit of shrubs and alpines were the dwarf conifers. They were in excellent condition and of good habit. Among them were six of the best dwarf conifers for the rock garden—Cupressus Lawsoniana lutea, Thuya elegantissima, Cupressus Fletcheri, Picea excelsa Maxwellii, Retinispora obtusa nana, and the smallest of all, Cupressus minima glauca. Any shrub to be used in the rock garden should be neat, small and compact in habit, and yet not stiff in form. Conifers have the advantage of being attractive throughout the whole year and slow growing. Messrs. Cutbush also had a large and varied collection of shrubs and alpines. The two shades of Cydonia Maulei and C. M. superba looked very fresh against some of the conifers, such as Picea nidiformis, Juniperus japonica aurea and Abies balsamea Hudsonica. A dainty little shrub shown by this firm, with minute bell-like white flowers, was Andromeda polifolia. The berried shrubs were naturally past their best, Cotoneaster horizontalis being in poor condition; but Pyracantha Lelandi still held a fine supply orange berries.

Some of the other exhibits were the following:

Apples and Pears.—Messrs. Bunyard and Co.

Citrus.—Mr. Cecil Hanbury.

Cyclamens.—Messrs. Stuart Low and Co., Caledonian Strain Floriculturists.

Orchids.—Mr. G. F. Moore; Mr. H. T. Pitt; Messrs. Saunders and Co.

Roses.—Elisha J. Hicks.

Rhododendron Leaves.—Messrs. B. and C. McLaren.

Shrubs and Greenhouse Plants.—Messrs. L. R. Russell, Limited.

Digitized by Google

Shrubs and Alpines.—Messrs. Carter Page and Co.; Mr. G. Reuthe.

Garden Contractors.—Johnstone Garden Contractor Company.

Gardening Books.—Messrs. Cassell and Co., Limited.

Landscape.—Mr. Percy S. Cane.

Vegetables.—Messrs. Sutton and Sons.

Horticultural Sundries, Tools, etc.—Abbott Brothers (bird boxes and nests), Ashtead Pottery, Limited (china bowls); E. R. Bugge (sprays and powders); Chase Continuous Cloche Company (adaptable plant protectors); Carter (labels and insecticides); A. Everitt (gardening gloves); Thomas Gunn, Limited (tools); Hardy Patent Pick Company, Limited (spades); J. Jardine (Médoc and Guienne secateurs); London Garden Florists (bowls); Radium Fertiliser Company (fertilisers); Mrs. E. Torkington (Wizard plant labels); John Pinches (labels); "Socleano," Limited (labels); Fraser Treleaven and Wilkinson, Limited (flower-pots); Charles H. Pugh Limited ("Atco" motor mowers); Ymagynate Pottery (china bowls, etc.); W. Wood and Son (sundries and tools).

NEW AND RARE PLANTS.

PRIMULA MALACOIDES COURTLAND SEEDLING.—This dainty little species, introduced from China in 1908, with its mallow-like leaves, has been much improved upon in late years, and there now exist several fine varieties. This variety, Courtland Seedling, had as many as twenty flower stems with more numerous whorls of flowers of a rose-lavender shade. The flowers were of good substance and size, while the plant has retained its elegance and grace of habit. The plant appears to be of good constitution, having, no doubt, inherited its robustness from malacoides. Award of merit. Shown by Mr. P. W. Carver, Courtlands, West Hoathley, Sussex.

PYCNOSTACHYS DAWEI.—This plant, with its short terminal spikes of deep blue flowers, is a valuable novelty from Madagascar and will be found to be of extreme service in conservatory decoration. One advantage which it has is that it will thrive at a fairly low temperature. It is a stout herb of from 4ft. to 6ft. high, with a loosely branched pyramidal habit with many crowded flowers. It certainly is a plant which deserves wider recognition. Award of merit. Shown by Mr. L. R. Russell, Richmond.

ORCHIDS.

CYPRIPEDIUM STAMPERLAND VAR. ALPHA (Glorita × Christopher var. Grand Duke Nicholas).—A finely developed flower, with all the segments well above the usual size. The dorsal sepal greenish, bordered with white and evenly spotted with purple; labellum broad and, with the petals, yellowish in colour, stained with red-brown. From Mr. Robert Paterson, Cathcart, Glasgow. Award of merit.

CYPRIPEDIUM WORSLEYI (Hestia × Lady Dillon).—This handsome hybrid is characterised by the dorsal sepal being boldly marked with large spots evenly distributed on a white ground, the basal area greenish; the broad petals bear brownish-red markings. From Mr. H. Worsley, Stonehouse, Haslingden, Lancs. Award of merit.

CYPRIPEDIUM MRS. ELEY VAR. DERRICK (Christopher × Warrior).—An attractive flower having the dorsal sepal orbicular in shape, green at the base, white above; petals and labellum yellowish, marked with brown lines and spots. From Mr. G. F. Moore, Chardwar, Bourton-on-the-Water, Glos. Award of merit.

LÆLIO-CATTLEYA PEPITA VAR. SPLENDENS (L.-C. St. Gothard × L.-C. Colmaniana).—A promising hybrid with compactly formed flowers, of deep mauve-pink colour evenly distributed throughout the sepals and petals, the labellum rich purple, and with the margin prettily crisped. From Messrs. Cowan and Co., Southgate. Award of merit.

A gold medal was awarded to a splendid exhibit of cypripediums staged by Mr. G. F. Moore, Chardwar, Bourton-on-the-Water, Glos.

NATIONAL ROSE SOCIETY.

ALTHOUGH the two hundred or so of members who attended the annual general meeting of the National Rose Society at the Caxton Hall, Westminster, on January 13th, is a small proportion of the 12,000 members, it was quite a satisfactory attendance. As Mr. H. R. Darlington remarked, when seconding the adoption of the Council's Report, it is notorious that shareholders usually take but little interest in annual meetings when the concern is successful, so the assumption is that the members are entirely satisfied with the management. Of the extraordinary success of the National Rose Society there can be no doubts. The membership increases amazingly, the balance on the year's working is enviable and gratifying, and £1,000 has now been invested in Great Western Railway stock, making a reserve fund of nearly £7,000.

Although the Society has been in existence about forty years, it does not seem very long ago when the members were numbered by hundreds, and, when comparatively recently, they became over two thousand, it was thought to be immensely successful. As Mr. Preston-Hillary said, the present success is due to the untiring energies of the hon. secretary, Mr. Courtenay Page, and the policy of the Council in, what we may term, giving the members value for their money.

The greatest interest of the meeting was centred in the proposal which appeared on the agenda, "That the Council be and is requested and authorised to apply to His Majesty's Privy Council for the incorporation of this Society by Royal Charter." In proposing the adoption of the motion, Mr. Preston-Hillary reminded the meeting that a similar proposal was made a year ago, when it was referred back for further consideration. The Council had appointed a sub-committee of four, who had given an enormous amount of time and consideration to the matter and, with the exception of Mr. H. R. Darlington, they strongly recommended the Council to apply for Incorporation. After full consideration of the sub-committee's report, the council had decided by 26 votes to 5 to recommend the annual meeting to adopt the proposal. A copy of the proposed Charter had been circulated, and Mr. Preston-Hillary briefly reviewed the salient points, emphasising the need for safeguarding the officials of the Society and the added dignity and improvement which would accrue. He also said that although Mr. Darlington strongly dissented, he had been of the greatest assistance to the committee in drawing up the proposed Charter. The motion was seconded by the Rev. J. H. Pemberton, who remarked that he was one of the oldest members of the Society and that he was strongly of the opinion that the growth of the National Rose Society demanded the improved constitution.

As there were no other nominations, the officers were all re-elected, and during the course of the meeting the result of the ballot of forty-two members for thirty-six seats on the Council was made known.

SPRAYING MACHINES

QUITE a few years ago, when writing of material improvements which had been effected in spraying machines by leading British manufacturers, I expressed the view that little room appeared to be left for further improvement in what might be termed vital points.

My admiration of the machines of that day was genuine, and perhaps the more profound by reason of the fact that while I had a lively interest in the work of a spraying machine I had nothing of that inventive genius which belongs to the masters of engineering and mechanism. To that is doubtless attributable my error in supposing to be impossible what has in fact been achieved; for the spraying machines of to-day embrace a number of improvements which, now that we have them, are readily recognisable as being of real importance.

Such recognition is, of course, dependent upon a full appreciation of efficiency in spraying machines, and it is my firm conviction that the machine is of even greater importance than the spray, because with a defective instrument the value of the best chemical mixtures prepared can be nullified.

In commercial circles spraying has made remarkable strides of late years, and to-day all successful fruit farmers, nurserymen, and also hop growers, include systematic and seasonal spraying among the essential items in their working programme. Amateurs are less progressive in this matter, for the simple reason that they have not the same facilities for acquiring a knowledge of all that spraying means, and in various ways the amateur is handicapped.

The commercial man, for instance, is provided with opportunities to witness practical demonstrations and tests by which he learns the advantages of the thoroughly efficient machine. He comes into direct contact with representatives of manufacturers who are competent to explain the particular points which make for success, and he therefore walks in the path of knowledge.

The amateur, lacking such privileges, is frequently thrown back upon the salesmanship of a stores assistant who deals with a spraying machine as he would with a vacuum cleaner or a knife cleaner. To one who has no practical experience the brightly lacquered container, the polished handle and general finish of an "X.Y.Z." type of machine makes as strong an appeal as the technically perfect "A.B.C." type, and price naturally becomes a deciding factor. Even when, upon good advice, one may ask for a machine of a certain model, a shop assistant may readily satisfy a client that "here is an equally good, or perhaps practically the same machine." The great point, however, is that polish and appearance are of precious little account; the essentials are strong, durable pumps of great driving power,

Digitized by Google

convenient shape for carrying, carefully devised means of filling, acid-resisting plungers, washers, etc., good lances,

and the best nozzles that ingenuity can devise.

A machine that works all right up to a point, but can never reach the tops of one's trees, is capable only of spoiling the whole effects of one's laborious spraying.

A machine that has power sufficient for needs, but which is of a weight or shape that prevents a man doing a good day's work with it, is something to shun.

A machine which has a well made pump but is fitted with a nozzle that releases a coarse spray, or that is continually choking, might as well be a bad machine throughout. For reasons such as these our leading manufacturers, true to the world-wide reputation of the British engineer, have sought to eliminate imperfections rather than to cut down cost of production to a point which means inefficiency. When seeking a spraying machine, even for limited requirements, it is wiser to study quality than economy in first cost, because without the quality both the initial outlay and the future cost of working will be little better than waste.

There was a time when a good many machines were sent out which were weak in vital particulars. Working parts were inaccessible either for cleaning or repair. Washers, and in some cases containers, were vulnerable to the caustic or corrosive action of powerful chemical sprays. Some were defective in the method of attachment of rubber hose, lances, etc., and nozzles were at one time prone to release the spray in the form of a funnel-shaped jet with hollow centre, rendering the perfectly even distribution of the spray over the entire surface of a tree a difficult and somewhat uncertain task. For a long time the method of filling machines of moderate dimensions was tedious and cumbersome, and altogether one needed a very strong faith in the power of spraying to persevere doggedly with a sometimes very disagreeable task. Thanks to careful interchange of views and ideas between manufacturers, pathologists and chemists the improvement of machines made highly gratifying progress, and to-day we have sprayers of convenient size for all requirements which are both highly efficient and are at the same time free from complicated operation. I had almost used the common expression that the machines of to-day are fool-proof.

When first the pneumatic spraying machines were introduced there was a division of opinion as to their value. Some urged that the charging of the machine with compressed air was simple child's play compared with the continuous pumping while the machine was harnessed to one's back. Others declared that the former was the harder work, that it was impossible to gauge the correct pressure required to discharge the whole contents of the machine, and they made much of the fact that the time occupied in charging the machine with air was greater than the time the sprayer could be kept working. These arguments held some weight, but that was before the advent of the "Weeford Pattern" knapsack sprayer, for which we have to thank The Four Oaks Spraying Machine Company, who have consistently kept abreast of the times in spraying matters.

The outstanding features of the Weeford are: the container or tank is made of brass alloy, which will withstand acids, alkalis and the combinations of chemicals used for spraying purposes; the machine is filled from the bottom by attaching a hose-pipe and pumping the liquid from a tub or bucket. The advantage of this method is that there is no over-running or spilling of fluid, as so often happens when the machine is filled from the top with the aid of a funnel.

Furthermore, it is unnecessary to re-charge the machine with air at every refilling, for upon shutting off the tap when the spray is exhausted the air is kept in the tank, and once pumping suffices for the day.

Other good points about the Weeford machine are the well fitted hose and lance and finely manufactured nozzles. The Four Oaks Company have always paid close attention to their nozzles, and two specialities worthy of note are the "Unchokable," which automatically clears itself in the event of a hard particle clogging the aperture, and the "Seneca," which is fitted with a lever, by turning which the spray may be made fine or coarse at will.

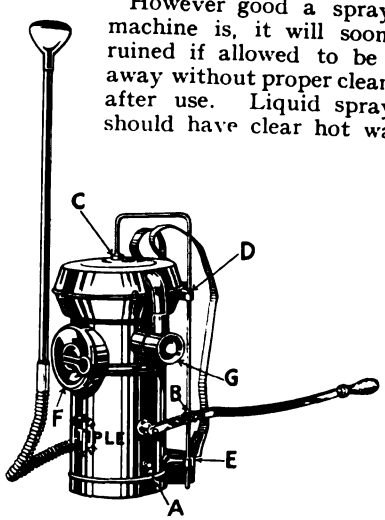
With such a machine the usual pump-fitted type of knapsack would seem to face a great rival, but there are excellent machines of that character for those who prefer them.

There is a distinct advantage in having the pump outside the machine instead of inside the tank, because whenever a new plunger is required it is a simple matter to disconnect the parts.

Of late years, dry powder spraying has gained considerable favour, and manufacturers have applied themselves diligently to the problem of meeting the demand for an efficient powder distributor of a capacity suitable for the requirements of an average garden.

Even distribution is as essential in the case of powder sprays as in the case of liquids, and the trouble with the earlier patterns of distributors was that they discharged the powder in successive gusts, depositing too dense a covering in one place and practically none elsewhere. The "Multiple" knapsack powder sprayer of Messrs. Robinson Bros., Ltd., is so finely constructed that efficient and even delivery is maintained, and with reasonable attention to a few simple details the machine may be kept in good working order for a prolonged period.

In the accompanying illustration of the machine the important "parts" are indicated by the letters as follows: A is a regulator button by which the discharge may be controlled; B is the plunger rod pivot, which will require occasional tightening after being in use for some length of time; C is termed the "stuffing-box"—here an occasional oiling will be required; D and E are guides for the plunger rod, where grease must be applied to assist easy working; F is the lid which, fitted with a pneumatic pad, must be shut down truly after filling, otherwise there will be a leakage while pumping; G is a dual valve port, a single valve port being on the opposite side of the machine. The leather valves are hinged, and upon their proper working depends the maintenance of ample force to drive the powder through the lance.



However good a spraying machine is, it will soon be ruined if allowed to be put away without proper cleaning after use. Liquid sprayers should have clear hot water poured in after the spray has been used, and by vigorously discharging this the interior of the machine will be cleaned. The outside should be thoroughly washed and wiped down with a dry cloth.

Powder machines should not be washed, but well brushed, and must be stored in a dry shed.

SIMPLE GARDENING

POTTING BEDDING-OUT PLANTS.

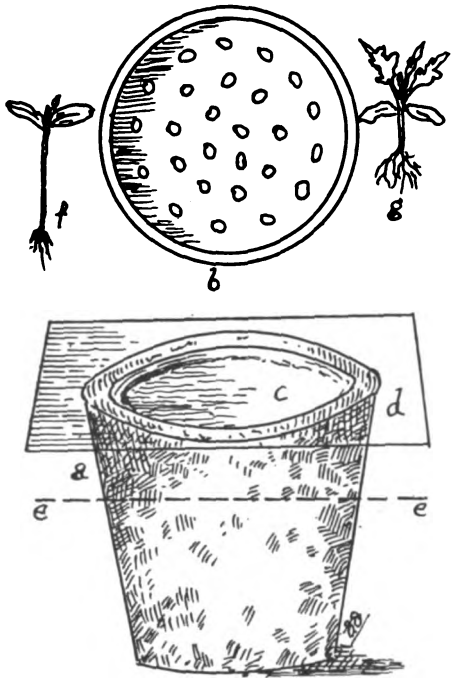
DURING August and September many thousands of cuttings of bedding-out plants are propagated in pots, pans and boxes. The cuttings chiefly dealt with are those of zonal pelargoniums, marguerites, heliotrope and calceolarias; but many more are cuttings of more tender plants. All, however, are usually crowded closely together in the pots and boxes, and it would result in partial failure if they were retained in them till the next bedding-out season came. So preparations should be made now to shift the cuttings to small pots, placing one specimen in each pot. Many of those cuttings of pelargoniums will not possess roots even now—only a hard callus with roots faintly showing through it. These plants will live through the winter in the condition referred to, but cuttings of other kinds rarely do. A good compost of loam, leaf-soil and sand will be suitable for the majority of the bedding-out plants, the more tender kinds requiring a greater addition of leaf-soil. The pelargoniums and other plants possessing few roots should be placed on one side, as the work of potting goes on. For these, extra sand should be mixed with the compost and a pinch of it placed at the base of each badly rooted specimen as potting is done. When the plants are potted they should be watered, but for a short period afterwards watering will not be necessary. Shelves and stages in the warm greenhouse should be occupied by the newly-potted plants.

SOWING SEEDS.

This is the beginning of the seed-sowing season when every lover of a garden, and especially every one who possesses a greenhouse or frame, will be busy with the first batch of seeds. These will be seeds of half-hardy annuals, for both greenhouse and garden, mainly. Of course, everything outside is cold now, and it would be bad policy to fetch soil pots and other requisites from outside stores and forthwith use them for the benefit of the seeds. Rather should all these things be brought into the greenhouse in boxes and allowed to remain there for a week or so before they are used. But in the meantime they should be prepared, the pots and crocks washed clean and dried and the soil sifted, a portion passed through a half-inch mesh sieve, a small quantity through a quarter-inch one and the remainder through a 1in. mesh. The latter will be just suitable for placing in the bottom of box, pot or pan. For all half-hardy annuals, such as asters and salpiglossis, boxes may be used and soil of an intermediate fineness, the more finely sifted portion being used to cover them the right depth. Of course, drainage should be sound, the surface soil level and watered before the seeds are sown on it, the covering soil not watered afterwards. For all dust-like seeds, such as those of begonias, the surface should be a little more sandy and no covering soil put on. Till germination takes place all seeds should be kept from the light.

RAISING EARLY TOMATO PLANTS.

Tomato plants are very similar to stove house plants: if they are not kept warm at this season of the year they soon fail, turn yellow, lose leaves and become very stunted, if they do not actually die. It would be bad advice if I encouraged cultivators to attempt to raise tomato plants at this early date without sufficient fire-heat. If a warm greenhouse is available, the work of raising young plants may be got on with. But many persons fail to grow the seedlings satisfactorily when they can command unlimited artificial heat. Fine soil answers well enough in the case of other kinds of seeds and resultant seedlings, but where tomatoes are concerned it frequently causes failure. The



seed pot or pan should be well drained, dry and clean, especially inside. The compost should consist of fibrous loam, reduced by hand, not sifted; leaf-soil, not too fine, either; and a nice sprinkling of old mortar rubble, in this case passed through a half-inch mesh sieve. Having filled the pot rather more than three parts, as shown at letter *a*, proceed to make tiny holes 1in. apart, shown at *b*, and half an inch deep with a blunt stick, drop one seed into each hole and fill them with fine soil, cover the pot *c* with a loose square of glass, *d*, and water when necessary by immersing the pot in water to the dotted line, *e*, *e*. Spindly plants, *f*, result when sowing is too thick, stocky plants, *g*, when seeds are sown as advised here. The seedlings need not be transplanted at a very early stage, and they rarely damp off as weaklings do.

EARLY CELERY, BRUSSELS SPROUTS AND CAULIFLOWERS.

The inexperienced cultivator must be very careful in the treatment of early celery plants, as any undue check to growth will result in "bolting." Too much heat, especially bottom heat, will also cause the plants to run to seed. Later, when temperatures are, generally, higher, plants raised under cooler conditions rarely run to seed. The few seeds sown now should be scattered evenly and thinly and just covered with fine soil. Place the seed pan on a shelf in a warm greenhouse, not in a propagating frame. For a very early crop a white variety is best. Brussels sprouts require a long season of growth, then the side sprouts will be firm and fit for use at an early date—in November. The plants are gross feeding, so it would be unwise to make use of poor soil for raising the young plants in. A fairly rich compost moderately firm is the most suitable. I prefer old chrysanthemum soil; failing such, use fibrous loam two parts, leaf-soil one part and well rotted manure one part. Sow the seeds in boxes, watering the soil first, but not after they are covered with fine loam; the seedlings break through in a more kindly way than is the case when the soil on them is caked. Cauliflowers should be treated in a similar way, but the tiny plants are more tender. In both cases any undue coddling would be harmful to the growths. Frame treatment is best, just keeping out frost and excessive moisture. The first transplanting should be done when the plants possess two rough leaves.

WINTER-FLOWERING CARNATIONS.

In some gardens these plants are propagated nearly all the year round. The amateur cultivator should insert cuttings freely now, as they are fairly plentiful and will form roots in a few weeks' time without the aid of bottom heat. The side shoots that make the best cuttings are those growing about 6ins. from the base of the flowering stem. Those shoots nearer the top are too sappy for cool treatment, but may be inserted where a gentle bottom heat is available. Of course, a propagating frame in a warm greenhouse is the ideal place in which to root the cuttings, but as such is not available in every garden a simple box arrangement should take its place. I have used boxes for many years with great success; they measure 2ft. by 18ins. and 12ins. deep. In the bottom a thin layer of quite rotted leaf-soil is placed, then a layer of washed sand 2ins. deep. The cuttings are inserted about 2ins. apart each way and then watered. The covering glass is wiped dry morning and evening, but care is taken to avoid overdryness of sand. The latter must be maintained in a moist condition, and to ensure this the cuttings are freely watered when the sand begins to dry up, the glass being left off the frame nearly a whole day at that time, but not at any other. GEO. GARNER.

THE LOVE OF TREES

I HAVE a notion that trees in this country are ceasing to be admired as much as they should be. I hope I am wrong, but it seems to me that in the first half of the nineteenth century everybody—man, woman or child—learnt to appreciate a tree, whereas nowadays they pass them by with scarcely a glance. The literature of the former period bears testimony to the general love of fine timber, and even an author like Thomas Love Peacock, who laughed at everything else, was fervent in his admiration. Possibly there were more of what might be called specimen trees in existence at that time, for books of the period mention many warriors which have since disappeared; now there appears to be a lack of young warriors approaching maturity. We seldom hear of new reputations being won for size, or beauty of outline, or grace of habit; certainly Elwes and Henry ransacked the country for examples for their monumental work on our trees. I have distinct misgivings as to the interest which the ordinary human takes in them.

It is true that people go in their thousands to see the chestnuts in Bushey Park on Chestnut Sunday. It is also true that they are magnificent with their great panicles of flowers, but once the flowering season is past they are forgotten except by those initiated into tree worship, and they are just as fine when out of flower. At the present moment there is an outcry against a proposed railway through the finest portion of Sherwood forest, which would probably mean the desecration of many forest giants, but the outcry is not nearly loud enough. It should be heard from the housetops. I have not actually seen these trees, except in photographs, but their destruction is more than a local matter, for remains of old forests are slowly disintegrating through time, and the sentiment of the nation should be touched to see another landmark ruthlessly destroyed. I believe that there is an alternative scheme which misses these relics of the Middle Ages, so everyone should exert their influence towards saving what little we have left to us of our landmarks in trees. If something is not done quickly, this, like many another worthy cause, will die of inanition.

Comparisons are odious, but I must draw the attention of my readers to the enthusiasm with which Americans regard their trees. They begin with a handicap because there are few individual trees either in the United States or Canada which are surrounded by any sentimental attraction. There is an occasional exception, like the Redwood in California, but there are very few. Yet both the inhabitants of Canada and the United States are keen lovers of trees. Large areas of the country are practically treeless by nature, which perhaps explains part of their affection. We, on the other hand, may be so accustomed to them that we think little about them.

Both the technical and the daily Press of America have frequent articles on the subject. I give below a sample taken from an American contemporary:

"A DOZEN DAILY THOUGHTS FOR TREE LOVERS.

"The following reasons why trees should be planted, protected and appreciated were advanced by a city forester in Chicago. We glimpsed them in a recent issue of *The Davey Bulletin* and gladly pass them along. They're good reasons, and true.

1. Trees are beautiful in form and colour, inspiring a constant appreciation of nature.
2. Trees enhance the beauty of architecture.
3. Trees create sentiment, love of country, state, city and home.
4. Trees have an educational influence upon citizens of all ages, especially children.
5. Trees encourage outdoor life.
6. Trees purify the air.
7. Trees cool the air in summer and radiate warmth in winter.
8. Trees improve climate and conserve soil and moisture.
9. Trees furnish resting places and shelter for birds.
10. Trees increase the value of real estate.
11. Trees protect the pavement from the heat of the sun.
12. Trees counteract adverse conditions of city life."

This is a good idea, and the twelve points mentioned should be hung up in every school, for no one can ever start too young to love trees. E. H. M. C.

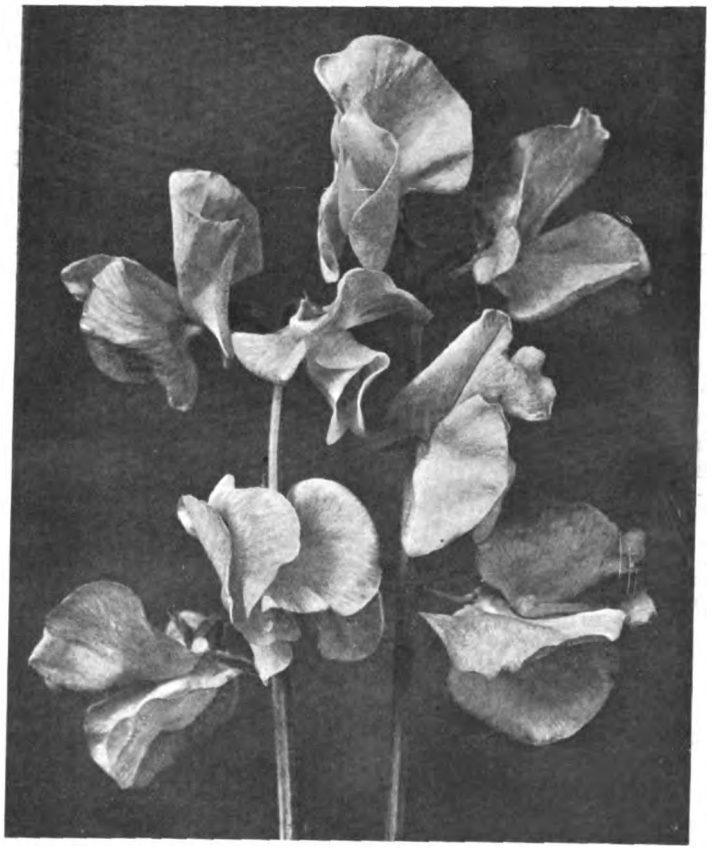
SUCCESS WITH SWEET PEAS

THAT THE POPULARITY OF THE SWEET PEA IS INCREASING IS EVIDENCED BY THE INTEREST WHICH IS TAKEN IN IT BY ENTHUSIASTS AND BY THE NUMBER OF NEW VARIETIES WHICH APPEAR EVERY YEAR.

ALTHOUGH it is fairly well known that autumn-sown sweet peas almost invariably give better results than those sown in the spring, there are far more sweet peas sown at the present time, or a little later, than in the autumn. I suppose every one of my readers has grown sweet peas, and in any case, everyone knows them well. Probably in no other flower have such great advances been made during the past few years. Compared with the sweet pea as it was twenty years ago, there is a really remarkable improvement, and although Nature presented us with a new type—the Spencer type—about 1903 as a "rogue" or "sport," the credit for improvements is mainly due to hybridists. One great reason for the increasing popularity of the flower is its ease of culture and adaptability. If one could apply the word "fool-proof" to flowers, one of them would certainly be the sweet pea. It will succeed on almost any kind of soil if given no more care or attention than one bestows on ordinary flower or vegetable crops, in spite of the elaborate cultural instructions one often hears and reads. Again, the sweet pea will respond to elaborate cultivation to a greater extent than almost any other flower, and give greater results for the care and expense entailed, I suppose over 95 per cent. of my readers do not grow their sweet peas for exhibition purposes, but simply for garden decoration and cut blooms. Serious exhibition culture entails, of course, a greater expenditure of time and care than ordinary culture, although I am aware that many with no thought of exhibiting grow their sweet peas on the "single stem" or exhibition system. Probably the excellence of the results they obtain more than compensates for the extra trouble.



ROYAL SOVEREIGN, BLOOMS OF A FINE ORANGE SCARLET.

Briefly, exhibition culture simply means that the sweet pea plants are transplanted 1ft. or more apart in soil which has been trenched and well manured to a depth of 2½ft. to 3½ft. and grown up on bamboo canes or other supports, the top growth of each plant being restricted to one, two or three stems. These afterwards are treated in the same way that one treats a tomato plant, all side shoots or laterals are carefully removed as soon as they can be handled, tendrils, too, are taken off before they develop. The plants are given all the nutriment the roots can assimilate without unbalancing them. To put exhibition culture in a nutshell, a highly encouraged root system throws the whole of its energy into a greatly restricted and pruned haulm, and it naturally follows that larger flowers and longer stems are obtained, but plants treated in this way will not, of course, give nearly the quantity of bloom that an unrestricted plant will produce if left to itself and grown naturally.

The fact that the sweet pea is very nearly hardy is not generally realised, and many amateur growers kill their plants through kindness, giving artificial heat or unnecessary protection, with the inevitable result that when transplanting time comes, they have thin or lanky plants which under no circumstances would give even fair results. Sow in the autumn if possible; if not, one may expect good results from a February or even March sowing, but the earlier the better. I need hardly tender the advice to obtain good seeds, they cost no more to grow than inferior ones. Although outdoor sowing in most districts is fairly safe, the majority of growers prefer to plant in pots or boxes in a cold frame or greenhouse, and transplant later. There is much to commend this method, especially with expensive seeds.

The best time for spring sowing is from the middle to the end of February. As a potting medium, any ordinary garden soil will do, provided it is porous and not too rich. Crock the bottoms of the pots or boxes, sow the seeds ½in. deep and allow about 2 sq. ins. of surface space to each seed. A little heat may be necessary to start germination if the weather is frosty. Water immediately after sowing if the soil is inclined to be dry. Until the young plants need transplanting in April, grow them along slowly, giving all the light and air possible. *The great secret is to keep the young seedlings sturdy and hardy from the time they appear through the soil.* I would emphasise the point that they are hardy and should not be treated as tender greenhouse plants. Mice may be checked by setting "breakback" traps. One cannot recommend the method of rolling the seeds in red lead or soaking in paraffin to check mice, as this does more harm than good. If birds are troublesome, cover the frame with fish netting, or a few strands of black cotton stretched just above the plants will prove effective.

Now as regards the preparation of the soil, this should have been done, of course, in the autumn, the earlier the better. One cannot lay down hard and fast rules, for naturally growers must adapt the time and method of soil preparation to their own circumstances. Provided one's object is simply cut flowers for the house, sweet peas will do quite well on soil which has just been dug over and manured, as for potatoes and other vegetable crops. If one is more ambitious, better results will follow if the ground is trenched or dug deeply, mixing in a good dressing of well rotted horse or farmyard manure to within 9ins. of the surface. It is not necessary to trench deeper than 2½ft. to 3ft. whatever one's object. By the way, there is no effective substitute for good horse or farmyard manure, and if these are obtainable, it is wise not to rely on artificials, for no fertiliser is cheaper and better than natural manure in the long run. In trenching, one may advantageously mix in a dressing of burnt wood ashes and bone meal or soot on nearly any soil. Sweet peas like a firm, settled soil. A large quantity of sweet pea seed is sown entirely in the open, and this can be done from the end of February to the second week in March, although here again autumn sowing is more satisfactory if the plants pull through the winter. Do not sow when the ground is in a sodden condition, for obvious reasons. In outdoor sowing, drills should be made with a hoe 1½ins. deep, allowing 2ins. or 3ins. between each seed. A dressing of soot on the surface of the row or clump after sowing will do no harm and checks slugs.

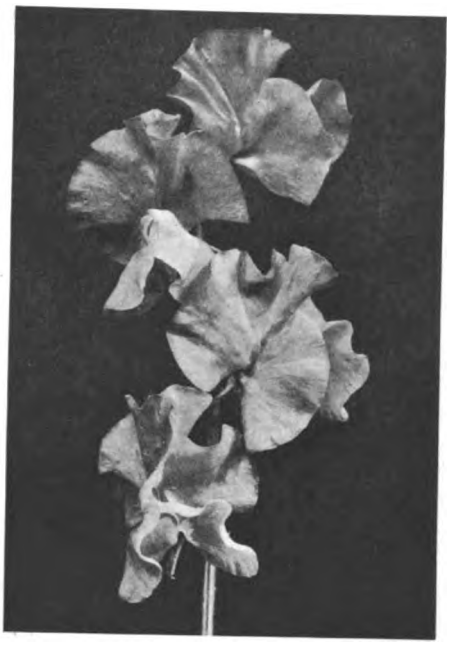
Digitized by Google

Planting out time will depend on the state of the soil and on the season. It can be done from the middle of March to the end of April, but keep off the ground if it is in a clingy or wet state and await a fine spell. Gently shake the old potting soil from the roots and throw away any plants which appear weakly when transplanting. I know that sometimes the advice is tendered that on no account should the roots be disturbed, but the above is my own method after repeatedly trying both. Should you intend to grow for exhibition purposes, plant out 9ins. to 18ins. apart, according to the vigour of individual varieties, but for ordinary cut flower purposes 4ins. to 6ins. is ample. Make the holes with a trowel or dibber, spread out the roots and gently fill in the soil afterwards, making the earth firm round them. Support the plants at once with twigs and take due precautions against slugs and birds. If the ground is dry, they may require watering, but do not do too much of this. Keep the surface loose with a hoe; in fact, one cannot be too energetic with this implement during the spring and summer months.

In a short article a detailed description of the exhibition system of culture is impossible, and to those of my readers who are not conversant with modern methods I would advise the purchase of a good practical book on the subject. Sticks or boughs and netting are generally used as a support for the plants, and these should be placed against them early, for it is detrimental to their ultimate success if left to fall about.

One hesitates to give advice respecting the treatment of the plants after they commence flowering, for this depends so much on the weather. The tendency among the inexperienced, I find, is to over-water and over-feed. After transplanting, it is rarely advisable to water until mid-June. Feeding the plants, too, presents a difficulty, for this not only depends on the state of the weather, but on the condition of the plants themselves. Artificial manures should not be used unless the grower has experience of their effect and knows for certain the right quantities to give. Always underdose rather than risk overfeeding. If the preparation of the ground has been really good, feeding may not be necessary at all, and pure, soft water only will suffice once every eight days to a fortnight, according to the weather. An excellent and safe liquid manure can be easily made by suspending a bag containing equal parts of cow or sheep manure and soot in a tub filled with water. Let this stand for a few days, and when watering dilute the liquid with two-thirds soft water. If the soil is very dry, give pure soft water before applying liquid manure. A surface mulch of horse litter or spent hops will retain the moisture and keep the roots cool in hot weather. To prolong the flowering period pick off dead blooms and do not allow seed pods to form.

The Editor has asked me to give a list of first-class varieties. I well know the difficulty the average grower experiences each season in knowing what varieties to select. He may read the selections of experts given from time to time in the horticultural Press and wonder why they vary considerably. The fact of the matter is that there is no such thing as the "best" dozen or eighteen. Some kinds which suit certain soils and localities admirably are seen to less advantage in other districts, while the weather conditions during successive seasons will be found congenial to certain varieties and adverse to others. Again, there is that element of personal taste which alone makes any selection unsuitable to everyone. It is even asking for trouble if one attempts to indicate the best variety in every colour section. I will give what I consider are the best twelve, but it must be understood that this is my personal choice of the peas I would grow myself. All those I mention are suitable both for exhibition or decorative purposes. They are as follows: Royal Scot, W. J. Unwin, Charming, Blue Butterfly or Mauve Beauty, Powerscourt or Austin Frederick Improved, Mrs. C. W. J. Unwin, Warrior or The Sultan, Royal Purple, Constance Hinton, Matchless, Picture or Hebe, and Unwin's Crimson, Charity or Crimson King. Other excellent varieties which would enhance a larger selection include Youth, Valentine or Edith, Mrs. H. Richards, Elegance or Comrade, Lady Gay, Royal Sovereign or Wizard, Sunset, Renown, Mrs. Tom Jones, George Shawyer and May Cowdy. Of these the following need shading in sunny weather: May Cowdy, Wizard, George Shawyer and Royal Sovereign, and the last named, although a most wonderful colour, also requires very good culture to obtain size. Where I have given two or more varieties I consider them practically equal in value, and readers may use their own judgment should they wish to follow my choice. It should be clearly understood, as I have said, that the varieties given will only suit certain tastes and conditions.



ROYAL SCOT, OF A CRIMSON SCARLET SHADE, SUITABLE FOR HOUSE DECORATION.

SWEET PEA PICTURE WHICH IS SUITABLE FOR EXHIBITION OR DECORATION.

It is now generally known that sweet peas, when grown under glass, alter their shades to a greater or less degree, according to the variety, and those which are excellent for under-glass culture are often unsuitable for one's garden. This is particularly noticeable in the orange, salmon and to a less extent the lavender, cream-pink and delicately flushed shades. I would advise readers who wish to grow sweet peas under glass to confine their selection of varieties to the whites, creams, cream-pinks, salmon-cream-pinks, flushes, salmons, cerise and orange shades, orange-pinks, blues, lavenders, and a few of the flushes and fancies that have salmon or orange in their colouring.

I have often been asked whether I think the sweet pea is practically played out as regards improvements; this certainly seems to be the position on the face of it, for there is now such a diversity of shades. When one considers the vast improvements that have been made, there seems little room for more. I am aware that a score or so of novelties are introduced every season, and from past experience I know that not one in ten of them is destined to become a general favourite, yet there is ample scope, for there are many colour sections which one would like to improve respecting their size and shape of flower or vigour of growth. In many colour sections, too, it is the colours themselves that need improving, and in some, all the existing varieties show a tendency to burn or fade, more or less, in the sun. Others are unsuitable for cut flower purposes, for they will not keep their original lustre after a day in water. We may get another valuable "break" or "sport" either as the result of crossing sweet peas among themselves or with another species, or perhaps Mother Nature may again take a hand and give us a new type as desirable as Countess Spencer was in 1903. It is almost a certainty that many real improvements have been passed unrecognised, for they cannot all have put in an appearance in an expert's garden.

CHAS. W. J. UNWIN.

HEATHS IN WOODLAND

HAVING a woodland garden, the trees being for the most part old oaks and the soil a light, shaley loam, we have done a good deal of experimenting with a number of dwarf flowering shrubs as undergrowth. Of these none has given us greater satisfaction than some of the hardy heaths, Erica carnea proving by a long way the best. Two or three years ago a piece of rising ground beneath some of the oaks was planted with this species and, notwithstanding the fact that the place had been a failure with various other plants, owing to the shade, the dryness and poverty of the ground, E. carnea has turned out an unqualified success. Indeed, I can at the moment call to mind no other shrub that will bloom with such prodigality in similar conditions and one wonders why it is not more often used in the woodland.

ERICA CARNEA, WHICH HAS PROVED AN UNQUALIFIED SUCCESS WHEN PLANTED IN WOODLAND, DESERVES TO BE MORE WIDELY USED FOR THIS PURPOSE.

Put into the soil in small clumps, such as one could easily grasp in one hand, with a little leaf-mould worked in around the roots, the heather went away from the start and quickly covered the ground, which, last January, when the accompanying photograph was taken, was a mass of colour. No sun, save that which filters through the branches of the old oaks, ever reaches the heather; but while it may be urged that these branches are leafless when the plant is in bloom, one has to acknowledge the fact that the flower-buds are formed when the oaks are in full leaf.

The E. carnea we grow in this way is simply a good form of the type, the flowers being a vivid carmine-crimson. Some of the named varieties appear to be equally robust and prolific, but these we have not tested under the above conditions. They afford a wide range of colours, from palest blush to something approaching a full crimson. What we really want in E. carnea, and what would be invaluable for woodland planting, is a pure white form which will flower as freely as the type. E. c. alba, at its best, is a poor thing, and we have abandoned it as worthless.

Though it does not flower so generously under trees as carnea, E. Darleyensis may be used in such a situation with no little satisfaction. Its habit of coming into bloom in November is much in its favour, and in foliage it is, I think, more pleasing than either of its parents, carnea and mediterranea. The last-mentioned we grow in groups in the woodland; but while it, again, is not quite so free with its blossom in full shade, we find that in places where it gets a little sun for part of the day, as on the outskirts of deciduous trees, it will put up a show of colour that fully entitles it to a place among woodland heaths. Moreover, E. mediterranea has a white form which is a lovely thing, rather shorter than the type, but an abundant bloomer with a compact habit. The variety known as hibernica (glauca) has a distinctive charm of its own and is, if anything, rather happier in shade than the species.

The only other heath which I can recommend, on personal experience, for planting in woodland is E. cinerea, our own bell-heather. This, together with a multitude of hybrid offspring, is a weed, and a very pleasant one, all about the banks and walks of our woodland garden. If it does not make such massive clumps, or bloom with such liberality in shade, or part shade, as in full sun, it seldom fails to make a worthy show of colour. The best variety for woodland planting is, perhaps, rosea, a very robust grower with fine heads of bloom in a full-toned rosy-crimson, free from that bluish tint that so often mars the beauty of the wild plant. Two of the newer varieties of this species, pallida and Apple Blossom, also promise well. A better drought resister for dry, poor, stony soils than E. cinerea I do not know.

I may add that in planting all these heaths in woodland the ground is merely cleared of scrub and weeds, loosened with a pick and forked over. A handful or so of leaf-mould is put round the roots, as suggested above, and the soil is not firmed in too hard. But one essential is really deep planting, that is, the plant must be put in well up to the green. Treated in this way, the job being done in autumn or spring, we rarely lose a plant. No peat is ever used. EE. carnea, mediterranea and Darleyensis are, by the way, said to be quite at home in a calcareous soil. A. T. JOHNSON.

HARDY FERNS FOR TOWN GARDENS

THE difficulties and problems of town gardening have provided a theme for many writers, but one is somewhat at a loss to explain why the cult of hardy ferns has not been more persistently advocated and enthusiastically embraced. Infinite charm and absorbing interest are the birthright of a tribe of plants which ask so little in the way of favoured conditions that instead of elaborating exacting demands and urging the necessity for special provisions one is disposed to query whether a garden exists where at any rate some of the robust species and varieties cannot be successfully grown.

Town gardeners, who, at the expense of much time and heroic effort, achieve just mediocre results in their endeavours to keep alive many kinds of plants that yearn for the unrestricted light of the sun and free circulation of pure air, might make a paradise of their gardens by specialising in hardy ferns, a hobby and an intellectual study not one whit less fascinating than the cult of the orchids of the magnate.

There is a reason for all things, and when I ask myself, as I frequently have done, why hardy ferns fail to attain the widespread popularity they so richly deserve, the answer I give myself is that a general impression exists that so elegant and graceful, so fragile in appearance are the gossamer fronds of the finer varieties that the term "Hardy" ferns must be a misnomer, and that such plants cannot

Digitized by Google

be expected to thrive in an ordinary garden. Pray let that impression be banished from the mind as an hallucination. Examine the accompanying illustration and judge of the rude health displayed by every plant in this particular choice collection. This photograph portrays a portion of Mr. Frank Butler's garden, enclosed by walls and buildings in the heart of Reading, a town garden in the full acceptance of the term.

One other point, I am convinced, helps to keep hardy ferns from their rightful position in the vanguard of popular plants, *i.e.*, their awe-inspiring nomenclature. Even to one accustomed to ordinary botanical names it must be confessed that contemplation of such an appellation as Polystichum angulare divisilobum nitescens grande is somewhat bewildering, and while readily acknowledging the necessity for an adherence to systematic nomenclature, it does appear in the case of ferns that the laborious system adopted savours of pedantry. Whatever might be the difficulties involved in revising the nomenclature of British ferns the task would be well worth while if the result would be the removal of an obstacle to their extended culture. Such revision may be accomplished some day, but meanwhile the bogey is not really so great as his shadow, and the lengthiest name becomes simple when once the first and essential principles of botanical rulings are grasped. Mr. Butler is an expert judge of dogs, and he assures me that mystified though he was at first by ramulosissima, ramocristatum, divisilobum elegantissimum and the like, he soon found the names quite as readily memorised and as intelligible as the registered names of pedigree dogs.

The great thing to realise is that hardy ferns are not difficult to manage, and will in fact grow where many commoner plants merely languish.

As may be seen from the illustration Mr. Butler's fernery is backed by a high wall, and butts on to a garden shed. For the greater part of the day the plants are in shade, but the major portion receive some sunlight in the afternoon. The wall in the photograph faces west, while the corrugated iron of a shed faces north, and there are tall trees, the roots of which ramify through the soil beneath the raised bank which forms the root-run of the ferns. The tree roots are no detriment, for they serve as drainage or absorbents of superfluous moisture, and it may be well to observe that the prevalent idea that ferns must have boggy conditions is erroneous so far as the great majority of species and varieties are concerned. Plentiful supplies of moisture during the growing season will be enjoyed, but stagnation is unhealthy.

Rough porous stones are utilised to produce a pleasing setting, and to retain the compost, which, by the way, is not entirely peat as many people imagine it should be. Some peat is useful, but fibrous turf loam, good oak or beech leafmould, plenty of pulverised bricks, limestone chippings, some charcoal and wood ashes make a highly satisfactory compost for most ferns.

The illustration shows some magnificent pieces of choice varieties and forms of Polystichum angulare, while crested Scolopendriums are prominent and particularly good. Mr. Butler's collection embraces a wide selection, and like every connoisseur he is incessantly seeking rarities and adding one gem after another to his treasures.

It would be an endless task to name all the ferns that are worthy of a place in a fernery, but as a nucleus of a collection the following are commendable. Allosorus crispus (the parsley fern), Asplenium Adiantum-nigrum (the black maidenhair spleenwort), Athyrium Filix-fœmina (the lady fern), in many beautifully crested varieties. Cystopteris fragilis (the brittle bladder fern), Lastreas in great variety, and Polypodiums of various kinds. Polystichum angulare must be afforded a prominent position, and effort should be made to obtain some of the finer varieties, such as P. a. parvissimum, P. a. divisilobum vars. and P. a. proliferum densum. P. Lonchitis (the holly fern) is a strong growing and effective plant, and the Osmundas (royal fern) must surely not be overlooked.

In Scolopendriums (hart's tongues) alone a wonderful range of variety and handsome form exists. S. vulgare crispum robustum, S. v. ramo-cristatum majus, and S. v. ramo-marginatum and many others, including those with yellow variegation of fronds being highly prized.

It would be unwise and destructive of the fullest enjoyment to attempt fully to stock a fernery in one initial effort. It is essentially a thing that should start from small beginnings, growing gradually as one's acquaintance with ferns and their individual characteristics improves, for this intimacy and keen delight in every occupant of the fernery is sustained and the hobby becomes a source of abiding joy as the fernery becomes an inseparable part of the home of which every garden should be an integral feature.

A. J. MACSELF.

A CHOICE COLLECTION OF HARDY FERNS IN A TOWN GARDEN.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its Readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

PLEASE REMEMBER TO MENTION "THE GARDEN" WHEN ANSWERING ADVERTISEMENTS.

THE HERB GARDEN

IN THE FOLLOWING ARTICLE ARE DESCRIBED MANY SWEET HERBS WHICH WILL BE FOUND TO GIVE FINE EFFECTS BOTH IN THE MASS AND AS INDIVIDUAL PLANTS.

THE ideal herb garden should be exposed in the main to full sun, but in it there ought to be some semi-shady nooks to suit certain plants, and if there be a little water —a streamlet or a small pond—for the benefit of such things as the moisture-loving mints, so much the better. The garden may or may not be sunk, but if possible it should be enclosed either by hedges of rosemary and lavender or by low walls, in the crannies of which thymes, valerian and house-leek may find a footing. Strictly speaking, of course, the two latter do not come within the category of herbs, but consistency may easily become a vice in gardening, and unless the plot be a very tiny one a certain number of "simples," that is to say, plants which have, or were thought to have in the past, a medicinal value may well be included.

How the space within the hedges or walls is laid out must depend on its size and, naturally, to a considerable extent on the taste of the owner; but, as a general rule, there should be a fairly wide border immediately within the boundary, with beds, neither very small nor very fanciful in shape, in the centre surrounding, perhaps, a bird bath—these are getting rather hackneyed, however—a good lead figure or a fountain and basin. Box makes the neatest "live" edging, but the hay-scented woodruff, which, according to the old writers "made the heart merrie" when put into wine, has a delightful effect when its snowy flowers are in bloom, while for a broad border nothing is more attractive than the soft grey-purple of Nepeta Mussini. Wooden rails painted green or brown, or treated with some rot-proof solution, make a neat, if rather expensive, edging, or small-sized rockery stones may be used.

We now arrive at the important question of stocking the garden. Here, again, dimensions and personal preference must be essential factors, but if space is limited it is well to relegate such things as fennel, chives, parsley and common sage to the kitchen garden and to eschew annuals with two or three exceptions. If there is no surrounding hedge, lavender and rosemary should be grown as bushes in the border. These must be kept well trimmed and renewed from cuttings every three or four years. Rosemary, by the way, "flourisheth best where the mistress is master," according to an old saying. The border, too, will be the best place for such things as santolina or cotton lavender, one of the "strewing herbs" of the old gaol-fever days, and artemisia, otherwise southernwood, lad's love or old man, beloved by countryfolk for Sunday posies and once held in repute as a moth preventive. The ashes of its branches, moreover, made into a paste were considered excellent for the encouragement of the budding moustache. The grey-greens of lavender, rosemary, santolina and southernwood will contrast delightfully with the rich yellow flowers like miniature suns in splendour of elecampane, the candied roots of which are said to be good for coughs. Elecampane is a strong grower and needs plenty of elbow room, as does the scarcely less showy tansy, the golden trusses of which are admirable for cutting, although the herb garden is scarcely expected to supply flowers for the house! In former times the leaves of tansy were used as a flavouring for Easter cakes and puddings, representing the bitter herbs eaten with the Paschal lamb, the puddings being made of breadcrumbs, eggs, cream, sugar and spice mixed—rather nastily one would think—with the juice of the tansy leaves. Butter-milk in which tansy had been steeped was held to be excellent for the complexion by our foremothers and, according to Gerarde, the leaves preserved in honey were "good against the gout." Another yellow-blossomed plant which takes up a good deal of space is mullein, whose big, woolly grey leaves used to be infused in milk to make a drink for consumptive persons.

Of plants equally suitable for beds or border one of the most beautiful in colour is undoubtedly the turquoise blue chicory, although its habit of growth is not pretty. Alkanet or Spanish bugloss, which, according to Culpepper, will cure nearly all the ailments under the sun, is a deeper blue and both harmonise pleasantly with the metallic tones of eryngium, or sea holly, the candied roots whereof are, or were, the basis of Colchester rock, and with the soft pink of mallow. In France the funny little, flat, round seeds of the latter are made into lozenges, but in England they seem to have no other use than to be strung into necklaces by children. Salvia Sclarea, one of the annuals which may be advisedly permitted in the garden, has flowers and bracts of pinky mauve and is very effective in a mass. Its common name, clary or clear-eye, indicates its medicinal use, and it is said that in the dark ages of cookery its stalks were boiled as a vegetable. Pot marigold is another annual which deserves admission if only for the sake of its gay colour and cleanly pungent smell. Its leaves, however, are quite a nice addition to a salad, and in the past the petals were added to broth.

If there is no wall for it, valerian—the dark red variety—must be grown in beds or border in full sun. It is still used in medicine and is beloved of cats, although it suffers less from the violence of their affection than cat-mint, which, unlike the rest of its kind, likes a sunny position. The old rhyme says:

If you set it the cats will get it,
If you sow it, the cats won't know it,

but this is mostly underrating feline intelligence, and as a rule any plant of this mint, whether "sown" or "set," will speedily become the centre of radiating lines of cat tracks and be rolled, rubbed and "nosed"—I do not think it is actually eaten—out of existence in a very short time. Cat-mint tea used to be drunk as a tonic in England and its use lingered later in America. The rest of the mints must have the dampest place in the garden. There are nearly a dozen varieties which may be grown, and all are more or less desirable except perhaps the white woolly mint, which is an ugly, coarse thing that will smother everything within its reach if allowed.

Two of the sweetest and most indispensable herbs are balm and bergamot. The leaves of balm, infused, have the reputation of curing a cold, and dried they are certainly delightful in a sweet-bag, to use the old name for our modern sachet. The flowers of balm are inconspicuous, and it has the drawback of being a persistent encroacher. The splendid crimson flowers of bergamot are, on the other hand, very good to look upon, and it is seldom an unduly rampant grower. It is beloved of bees—its common name is bee-balm—and its delicious fragrance is well known. The oil used in the manufacture of the famous perfume, however, is not extracted from the herb but from the rind of a citron, Citrus Bergamia, grown in Italy, which has a similar odour.

The scent of horehound, celebrated for its cough-curing properties, is distinctly disagreeable, and Spenser's description of rue as "rank-smelling" is only too fully justified, but the delicate beauty of the blue-green foliage of the latter goes far to compensate for this defect, and it has many useful attributes. It was another of the strewing herbs. It has tonic properties, its smell is said to keep off objectionable insects, and its leaves pounded with butter and made into pills form a poultry medicine much relied on by old-fashioned hen-wives. Another herb which appeals more to the eye than the nose is the greater celandine. Its double form is handsomer than the single, and the thick orange-coloured juice is equally efficacious as a cure for warts—this is a true saying—in both varieties. Celandine seeds itself very freely and is apt to become a nuisance if not closely watched. Sweet Cicely, Myrrhis odorata, is another plant given to lavish seeding, but one can do with a big patch of its graceful fern-like leaves and umbels of snowy flowers.

If the beds are edged with rough stones, the thymes will be as happy there as in the crevices of a wall. The silver, golden, crimson and variegated kinds should all be grown, as well as the common lemon thyme. Thyme has other uses besides that of flavouring veal stuffing. It is often one of the many ingredients in the herb tea made by villagers as a spring medicine, and its oil, formerly regarded as a specific for toothache, is still employed in various medical preparations, although much of the commercial "oil of thyme" is in reality extracted from marjoram, one of our most valuable kitchen herbs.

Space will not permit anything approaching a comprehensive list of what may be grown in a garden of herbs and simples to be given here. It is only possible to say that besides

Digitized by Google

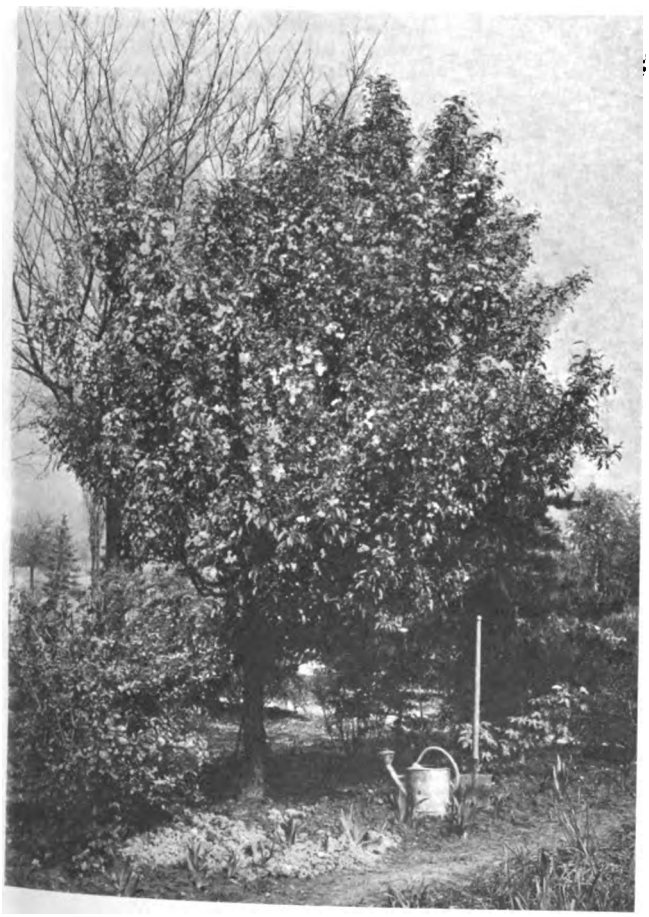
the plants named in this article room should certainly be found for wormwood—known to fame as the basis of absinthe—tarragon (not hardy everywhere), St. John's Wort, hyssop, "fresh costmary and healthful camomile," pennyroyal (which will nestle among the stones) and true saffron, Crocus sativus, still used although far less than for both flavouring and colouring; while if more annuals are admitted, they should include anise, carraway, coriander and dill.

K. E. HEAD.

PLANTS NEW AND NOTEWORTHY

THE "tea" apple tree is a Chinese introduction of Mr. Wilson's, who consumed the tea made from its leaves while in the wilds of China. The tea made of the leaves of Malus theifera is not of such a high quality as the best Indian tea, but can, perhaps, be used as a substitute in case of emergency.

The tree, as the accompanying illustration shows, is, when grown in a European climate, a rather strong grower and can attain a height of 12ft. to 15ft. Two points make it an interesting addition to existing decorative trees. First,



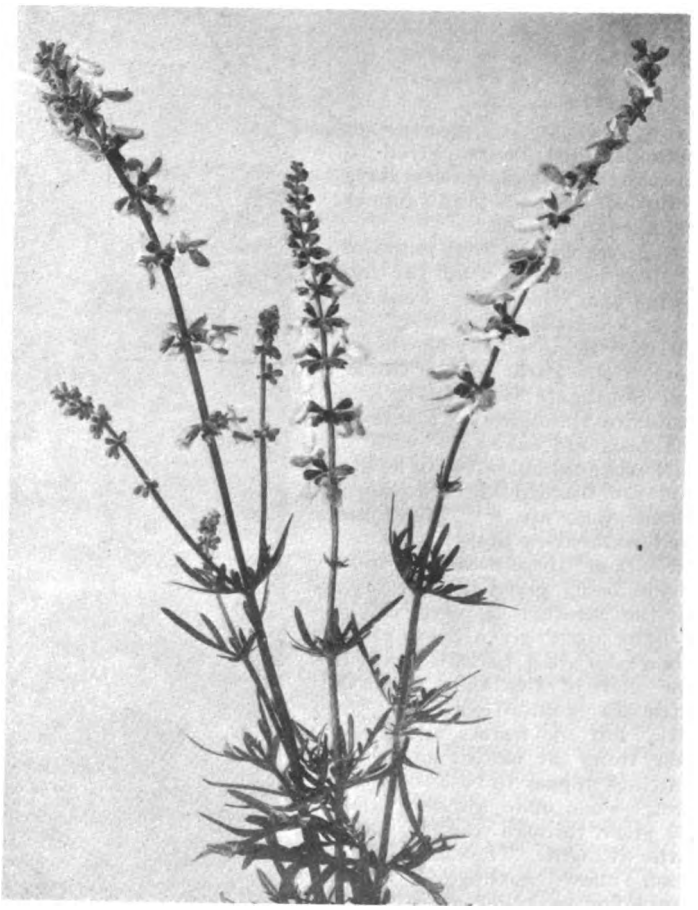
THE "TEA" APPLE TREE FROM CHINA, MALUS THEIFERA.

the flourish that is always at its best in May, the flowers look like those of a prunus, large, of a lovely white colour slightly suffused with pink and very freely produced. These flowers possess the peculiarity of being fragrant, which is rare in apple blossom. Then the fruits are very attractive in autumn. They are of the size of a large pea, borne at the end of long pedicels, much in the way of those of Malus baccata, a related species. They are bright red in the case of the tree here figured —introduced under the number 1129 of Wilson—but sometimes yellow or orange in the case of trees introduced under other numbers. They remain on the tree from August, when they begin to take colour, until October and November.

The tree is readily propagated by seeds, or, if one wants to gain time, by budding or grafting on any ordinary apple tree stock. Its culture is very easy as it grows in any soil and position, provided it gets a fair share of sun. It is perfectly hardy and requires no special care. Perhaps not a very strong grower at first, it soon makes a head once it feels at home. The habit, in all cases, is rather stiff and compact.

Salvia Jurisici is a plant from the Balkans described some years ago by Dr. Kosanin, of Belgrade University. It grows in the plain of Ovce Polge, between the towns of Koumanowo and Stip, in northern Macedonia, in association with Adonis flammea, Onopordon illyricum, Inula Oculus-Christi, Peganum harmala, etc.

In cultivation the plant has proved most attractive for the rock garden, grown either as an annual or as a perennial. In the rock garden of Messrs. Ph. de Vilmorin, at Verrières, for



A MOST ATTRACTIVE ANNUAL FOR THE ROCK GARDEN SALVIA JURISICI.

instance, where it was grown from seeds received from Dr. Kosanin, it was a lovely picture both this year and last year in the late summer. It reaches a height of 1ft. to 1ft. 6ins., and bears a profusion of violet blue flowers, slightly varying in shades. The flowering period is long, owing to the fact that side shoots are produced that keep on sending up new flower spikes.

A characteristic of Salvia Jurisici is the quantity of hairs on all its parts. The hairs are close, very thin and long, the stems square and the leaves sessile, formed of nine lobes, the terminal one distinctly more developed. Flowers are verticillate, their lower lip conspicuously keeled and most villose, measuring about one third of an inch in length; the upper, less developed, trilobate, villose only outside.

The propagation of the plant is very easy, as seeds are freely produced. These seeds, sown in March, give a beautiful show the same season, in August and September, precisely at a time when the rock garden is rather poor in flowers. When grown as a perennial, the plant will flower somewhat earlier and is best in a well drained and warm position.

THE RAISING OF BEDDING PLANTS

AN ARTICLE BY AN EXPERIENCED AUTHORITY ON THE GENERAL ROUTINE TO BE FOLLOWED THROUGHOUT THE YEAR IN ORDER TO RAISE BEDDING PLANTS SUCCESSFULLY.

MUCH has been written in various books on the above subject by men of wide gardening experience, but as no two persons employ the same methods, perhaps my system would be a help to some, and draw from others a helpful criticism. One often reads articles in weekly gardening papers from a southern grower, but the information is seldom of much use to anyone north of the Trent, therefore I thought my experience for the past five seasons might be helpful for the northern counties.

To begin with, our glass at Levens Hall—of which the mere mention of the name conjures up visions of topiary work—is not structurally adapted for raising bedding plants, so that unorthodox methods must be employed to raise the 30,000 plants necessary to furnish the beds for a summer and autumn display.

August sees the first batch of cuttings being taken for the following year's blooming. Pentstemons I usually take first, the varieties being chiefly Newberry Gem, Balls Park, George Home, and Southgate Gem. The side shoots of the flowering plants in the beds are taken off with a heel when about 4ins. in length and are dibbled in cold frames about 3ins. apart. These are well watered in and kept close for about three weeks, a light shade being given if necessary. If the weather is very bright a light spray given every afternoon is of great benefit. About the end of the third week a little air is admitted during the day, but the frames are closed last thing at night, until the cuttings appear to be "on their feet," when more air can safely be given through the day and a little at night. The cuttings will soon show by flagging if too much air is being given, or if they can stand without shading. I believe in keeping the frames closed and shaded until there is no fear of a cutting flagging, for once that occurs the cuttings will take weeks longer to root so that a lot of valuable time will be lost. On the other hand, as soon as the cuttings are able to stand having the lights pulled right back during the day, the better they will be for that treatment, as it is fatal to coddle cuttings which have to spend the winter in cold frames. Ivy geraniums are ready about the end of August, and these are struck in boxes placed in the next row of cold frames to the pentstemons, and receive the same treatment for the first four or five weeks, after which they are placed on shelves in a cool greenhouse and are kept fairly dry at the roots after September. My favourite variety is Chas. Turner, but I grow a few of Mrs. Hawley and Sir Percy Blakeney. A batch of heliotrope is put in towards the end of the month, but these are struck in boxes which are placed in heated pits. I usually find room for them in a frame which has grown a crop of cucumbers, placing the boxes on the old hot-bed. A good watering in, slight shade, and a spray over every day is all they require for the first month, when they are ready for potting up in sixties. They are then returned to the pits for a fortnight and afterwards brought into the little melon house, which is usually just finishing its second crop. That brings us now to about the middle of October and our first taste of frost. Begonias, dahlias, Lobelia cardinalis and Salvia patens are lifted from the beds and brought into the sheds to be dealt with. The begonia bulbs are rubbed over to clear as much soil off them as possible and are then laid thinly on the floor and on the border in the vinery to dry. As soon as they are perfectly dry they are stored in deep boxes with plenty of dry sawdust, and put in a frost-proof loft for the winter. Dahlias are lifted and laid under the solid staging in the carnation house, where they usually winter very well. Lobelia cardinalis is boxed up as lifted, a little old potting soil being worked among the clumps. They go into frames which have a single flow and return pipe running through as they keep better if on the dry side. It is nearly impossible to keep things on the dry side in cold frames during the winter months in this part of the world, so I find it best to make use of the heated frames. Lobelia cardinalis, unless kept fairly dry in the winter, makes very thin growth in the spring, and never grows into good plants in summer. Salvia patens I treat on similar lines. During November and December there is very little actual work among bedding material but a lot can be done in preparation for the turn of the year. Boxes are all overhauled on wet days by the outside staff; all pots washed and put into their proper sizes; loam, leaf-mould and sand stored under cover. The houses are all well washed down and given a coat of paint, and cracked and broken glass made good. The frames are also looked over and repaired so that, as far as possible, everything is ready for the spring.

FINE SPECIMENS OF THE DOUBLE WHITE ANNUAL LARKSPUR.

January is the time to sow for the first batch of seeds, and a start is made with antirrhinums. I usually grow about twenty varieties of tall, intermediate and dwarf types. The chief varieties in the tall section are Harmony, Salmon Rose, Orange King, Vermilion Brilliant and Yellow. Intermediates: Bronze King, Empress, Queen of Bedders and Sunset; and Yellow Prince for a dwarf. About January 14th I sow one box each of the tall and intermediate varieties in seed boxes about 4ins. deep. I always use new loam, with plenty of good leaf-mould and lime rubble, just covering the seed with a sprinkling of fine sand. Towards the end of last year the boxes were made up with soil which should be watered with boiling water about an hour before sowing. After the seed is sown, the boxes are stood on the evaporating troughs in the vinery. The boxes are covered with glass and shaded with paper. As soon as the seedlings appear, the glass and paper are removed and when they are large enough to handle they are pricked off into boxes filled with loam, leaf mould and lime rubble, with a sprinkling of bone-meal to each box. They remain in the vinery until they are about 4ins. high, and are then transferred into the heated frames, and the boxes raised on staging, so that the plants are about 6ins. from the glass. This moving usually takes place about the end of February or beginning of March. At first they are kept close and sprayed over every morning with luke-warm water. A week of this treatment is usually sufficient to get them over the slight check of removal from the vinery.

Digitized by Google

A little air is given after the first week in frames, increasing this until, by the end of March, they are ready for cold frames. Very little air is given at first, but in about a week they can stand plenty of air by day and a little all night. Early in April the boxes are removed from the cold frames and stood along the paths in the garden, but frame lights stood on pots are used to protect them at night for about a week or ten days. The end of the month the beds are all raked over and made ready for planting which usually takes place early in May if the conditions are suitable.

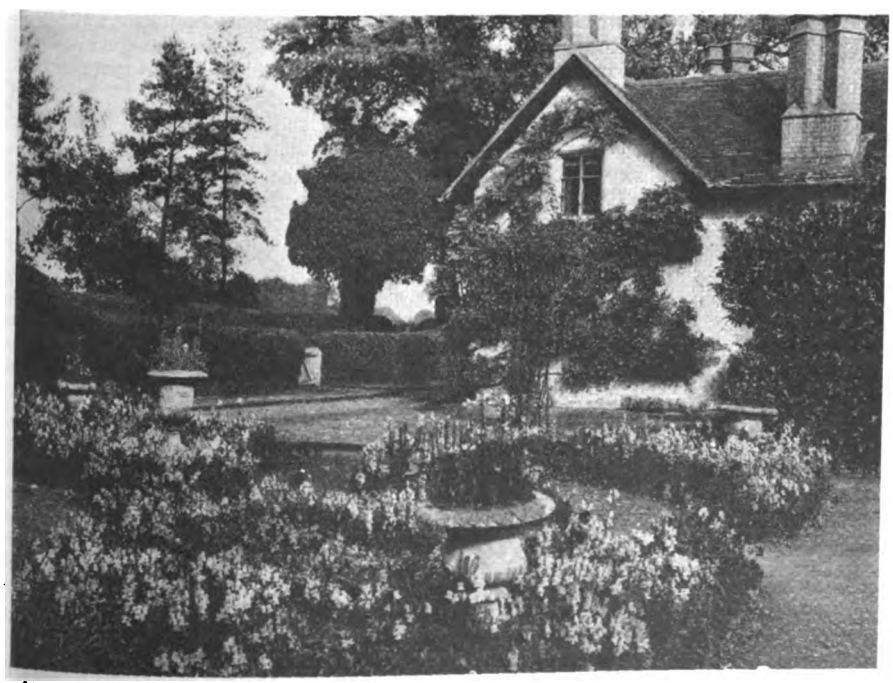
A week or ten days after the first batch is sown I make a further sowing of tall, intermediate and also the dwarf Yellow Prince. These are sown in boxes about 5ins. deep, as they sometimes come along a few days earlier than I can handle them, but they take no harm if the boxes contain plenty of good soil. This second batch is usually pricked off into cold frames about the end of March, so in order to make room for them I lift all the pentstemons with a trowel and have them laid in thinly on a warm border. They seem to like the change for they grow into nice sturdy plants and are ready for the beds early in April.

After the pentstemons are removed, the soil in the frames is forked over and given a covering of sand, and the second batch of antirrhinums is pricked off about 3ins. apart each way. At first they are kept close, but are gradually hardened off until, by the middle of May, the lights are left off day and night, and the end of the first week in June sees them planted out in the beds. During the past five seasons I have noticed the plants out of boxes do far better than out of frames. I may mention that at no stage of their growth are they stopped in order to make them bushy, as they are well furnished with bottom growth at planting time, and early in July the centre spike is showing colour. In a favourable season most of the centre spikes are used for house decorations and the side shoots then soon rush into a full blaze of colour. Another advantage in blooming the plants early is that one is able to detect the rogues and if these are pulled out, the remainder have a good chance of filling out, so that when the plants are in full bloom one is assured of having a bed true to colour. Many varieties are easily rogued in the seed boxes or when pricking out, and again at planting-out time.

MIGNON DAHLIAS, WHICH ARE SOMEWHAT UNUSUAL BEDDING PLANTS.

Two boxes of ageratums are sown along with the first batch of antirrhinums. These are also sown in fairly deep boxes and placed on the pipes in the vinery. Not until the leaves touch each other after being pricked off 3ins. apart in boxes of leaf-mould and sand, do they come out of the vinery and then only into a greenhouse with a night temperature of about 5° lower. When removed to the heated frames they are given the warmest end and stay there until the middle of May with a little air on all day, and are then transferred to cold frames, as the sun usually has sufficient power to keep them warm at night if the frames are well exposed to the sun and not too much air left at night. About June 20th they are planted out in beds, but a week previous to this they are left day and night without lights in some sheltered corner. Fibrous rooted begonias are sown about the third week in January, in pans containing leaf-mould and sand. As soon as the seedlings are large enough to handle they are pricked off into shallow boxes containing leaf-mould and sand in equal parts with just a little well dried cow manure rubbed through a fine riddle. They are then gradually hardened off ready for planting out time. Delphinium Azure Fairy and Blue Butterfly are sown about January 21st in boxes which are placed in the vinery. I find they make better plants if potted in sixties instead of being pricked off into boxes.

Salvia splendens is sown about the same time, putting the seed pans into a little forcing house, and as soon as germination takes place, the seedlings are kept going with plenty of heat and moisture. As soon as possible they are potted into "thimbles," and afterwards into sixties. When the pots are filled with roots they are fed with liquid manure and about the end of April are moved into forty-eights. By this time the cuttings of ivy geraniums, fuchsias and heliotropes are ready for potting up, and are stood pot thick in the heated frames for a time. The ivy geraniums and fuchsias are planted out in forty-eights, but I usually pot the heliotropes into thirty-twos. They make fine plants and are in flower by the time it is safe to bed them out. The boxes containing stools of Salvia patens are brought into the vinery to encourage growth early in January. The growth



FINE BEDS OF ANTIRRHINUMS FROM SEED SOWN IN JANUARY.

Digitized by Google

is taken off as cuttings, with or without a heel, and dibbled into boxes. A piece of glass, with a sheet of paper for shade, is put on top of the box. Although I was always taught that glass over cuttings should be dried at least once a day I never touch the glass over my salvia cuttings for a week, and have no difficulty in securing a 95 per cent. strike. Cuttings of Salvia patens may be put in up to the first week in March.

Blue larkspur, annual scabious, salpiglossis and nigella, are sown towards the end of February. In about three weeks they are ready for pricking off into boxes and are then moved into heated frames. Lobelia Blue Stone is sown about this time, but as the seed is so very small, it is sown on top of fine sand, care being taken to see that the pans are well soaked previous to sowing. Anagallis, alonsoa and another lot of lobelia are sown about a fortnight later. Early in March Lobelia cardinalis begins to claim attention. The boxes are given a good watering to encourage the lobelia to make good growth. Towards the end of the month the clumps are taken out of the boxes, and all the strongest shoots cut off with a knife, taking care to leave a bit of root to each shoot. They are planted out into a cold frame which has previously been enriched with well rotted manure. I have only tried three varieties here, Firefly, Lord Ardilaun and Queen Victoria. The last named is by far the best in colour and size of foliage and length of flower spike. Early in March the begonias are showing signs of growth and it is as well to have them laid out thinly in a frost-proof shed or a cool, dry greenhouse, as the little shoots are very easily broken off if they are handled much by having to turn them out of boxes of sawdust. Early in April is soon enough to put them out into frames. The bulbs may be laid on about 3ins. of rough leaves and just sprinkled over with leaf-mould. This treatment is good enough for Begonia Caltonii and Worthiana, but the dwarfer Dr. Deliuel, Evelyn Tavenent, Le Flamboyant, M. Essyer and President Savoy are best grown on in small boxes on the staging in a warm vinery. I am afraid space will not allow of much more on the subject from me, but I have tried to give as near as I can the dates for sowing various plants for bedding as carried out at Levens. Bedding plants appreciate good culture, and the best one can do for them is not too good if one wants a blaze of colour during the summer. F. C. KING.

BOOKS ABOUT PLANTS.—III

DEALING WITH GROUPS, FAMILIES OR GENERA.

I NOW come to a slightly more advanced stage, to books which deal with some specific plant or group of plants. It may be imagined that these books are meant for specialists, but every keen gardener, even though he be only a beginner, is a specialist in embryo. It is impossible to like all plants equally, and sooner or later his judgment will crystalise and his preferences will appear along certain fixed lines. It is then that these books on individual plants are so useful. I should mention here that before the war there was a series of small volumes on individual plants called the "Present Day Gardening Series." These are practically all out of print, so they are not mentioned individually.

I will try to give a selection of books on a few subjects:

CONIFERS.—"A Handbook of Conifers" by Messrs. Dallimore and Jackson, published by Edwin Arnold. A new book and the most concise and complete that has yet appeared. It contains every conifer, whether it is in cultivation or not. There is an American book, published by Macmillans, called "The Cultivated Evergreens," which also includes broad-leaved evergreens, but mostly consists of conifers. For those who are restricted to dwarf varieties there is a volume specially devoted to them called "Dwarf and Slow-growing Conifers," by J. Murray Hornibrook, and issued by *Country Life*.

RHODODENDRONS.—The two great books on this most popular genus are "Rhododendrons and Their Various Hybrids," first and second series, by J. G. Millais, and published by Longmans Green. They are very complete, but are rather large and so expensive. For those who wish a smaller volume, there is "Rhododendrons for Amateurs," published by *Country Life*.

PRIMULAS.—The most valuable contribution to this genus is the report of the Primula Conference held in 1913 and published in the Journal of the Royal Horticultural Society for 1914. A more localised book is "European Primulas," by J. Macwatt, published by *Country Life*.

SAXIFRAGES.—For rock garden enthusiasts Messrs. Irving and Malby's book on "Saxifrages or Rockfoils" is a necessity. It is published by Headley Brothers and is most complete in its information.

IRISES.—For this most important genus there are two books, both by W. R. Dykes, which say all that there is to be said about irises. He has made a life study of them and his knowledge is world wide. The large, folio volume, called the "Genus Iris," published by the Cambridge University Press, is really a work for the specialist as a large portion of it is botanical; for the amateur I should suggest "The Handbook of Garden Irises," published last year by Martin Hopkinson, which gives all the information that anybody outside the ultra-specialist can require.

ROSES.—First and foremost comes Miss Willmott's famous work on the "Genus Rosa," in two large quarto volumes, which is now published by Wheldon and Wesley. This is a magnificent book and is illustrated by Alfred Parsons, R.A. Probably the most important book on the rose for the amateur is "Roses: Their History, Development and Cultivation," by the Rev. J. H. Pemberton, Vice-President of the National Rose Society. This is a very useful book and fulfils all the requirements of the amateur. Another useful little book is "All About the Rose in Simple Language," by Sir J. L. Cotton, Bt., published last year by Andrew Melrose, Limited; while yet another is "Roses and How to Excel with Them," by R. V. Giffard Woolley, a *Country Life* Publication.

LILIES.—Although these flowers are so popular this is a between-season for books on the subject, for Mr. Grove's first book is out of print, as is Mr. Elwes's big monograph on the lilies. There are, however, two new works in course of preparation, which, I believe, are to be announced shortly.

BULBS.—There are two new books on the subject, one by the Rev. J. Jacob, "Hardy Bulbs for Amateurs," published by *Country Life*, an exceedingly useful book which includes notes on all bulbs which are usually grown, with lists of selections. The other, "A Handbook of Crocus and Colchicum for Gardeners" is by E. A. Bowles, and published by Martin Hopkinson. This is a most complete work and is invaluable for all gardeners who are interested in these two genera.

CARNATIONS.—"Perpetual Carnations," by L. J. Cook and published by *Country Life*, should supply all the information necessary for the amateur.

CHRYSANTHEMUMS.—"The Culture of Chrysanthemums," by W. Wells, another *Country Life* book, is very useful for their successful treatment.

DAHLIAS AND PEONIES.—For these we have to go to the United States. "The Amateur's Book of the Dahlia," by Miss C. H. Stout, is published in this country by Heinemanns, and is an admirable book, while "Peonies in the Little Garden," by Mrs. Edward Harding, and published by the Atlantic Monthly Press of Boston, supplies all the information necessary for their raising.

TOWN GARDENING.—This is a subject which is not well supplied with literature. For actual planning of public gardens we have to go to an American book which is called "Landscape Gardening," by O. C. Simonds, and is published by Macmillan. In this are several chapters which are useful to town architects. There is a volume called "Town Gardening," by Mary Hampden, one of Thornton Butterworth's "Home Garden" books, which is only partially successful; but this is a difficult subject and requires long experience. There is, however, a most excellent book on trees in towns, called "London Trees," by A. D. Webster, published by the Swarthmere Press, which is full of information of the greatest use to all town planners. M. C. E.

CORRESPONDENCE

DESTRUCTION OF SNAILS AND SLUGS.

SIR,—I should be extremely obliged to your correspondent, A. D. Richardson, if he would give fuller particulars of his experience of the use of powdered alum for the destruction of slugs. Does powdered alum remain effective after rain if broadcasted (after the style of dusting soot or lime, the old-fashioned way), or has it to be renewed after every shower? Would the price be prohibitive in dressing a two acre kitchen garden? Your correspondent advises making a strong solution by dissolving a lump of alum in boiling water and saturating refuse heaps. How much alum to, say, ten gallons of water would make a strong solution? Last season I tried soot, lime, Vaporite, Terafumite and Bentley's Slug Destroyer, with very little success, but was fairly successful with a home-made wash sprayed on seedlings outside every third evening. The wash was made up as follows: 1 gill Spidacide, 1 pint quassia extract (double strength), 1 handful of soft soap, 1 handful of yellow sulphur and 3 gallons of warm water.

I came to the conclusion hand-picking was the most effective way of dealing with the pests. With a strong darning needle and a tin with a little Vaporite in the bottom, six "hands" and myself could average 800 slugs an hour *each*, and putting in three hours a day managed to account for 15,000 a day in the kitchen garden alone. We kept it up for over a fortnight, but still the slugs appeared as numerous. Nothing came amiss, for after all weed seedlings had been consumed in addition to the usual vegetables, such as lettuce, cabbage, cauliflowers, broad beans, peas, parsnips, beet, carrots, onions, leeks and celery, hundreds of slugs could be seen crawling up the pea sticks and gooseberry bushes, and feeding on the green leaves of the latter. The same damage was done among annual flowers and herbaceous stuff. I should be pleased to give powdered alum a trial, but I think I shall try ducks. It would be interesting to have the opinion of readers of THE GARDEN on this question.—F. C. KING.

SEED POTATOES.

SIR,—An interesting contribution by "Clydesdale" on page 28 calls for a few special comments. It is not many years since those who possessed even adequate garden space invariably neglected planting anything but the earliest potatoes, being content to rely in the main upon farm produce for the bulk of their supplies. Nevertheless, the conditions of things as we find them to-day, notably, high prices, disease, national security against new methods of warfare, not to mention the desirability of rotation in cropping, demand that bigger areas be allotted for the culture of the humble potato. "Clydesdale" over and over again makes use of the term "small" when advocating the selection of seed, but it is not always easy to convey to others even an approximate conception of what is really implied by the use of such a term, far better give it in avoirdupois. I find a tuber of 1½oz. to 2oz. best calculated to obtain desired results, and yet in the selection of my "seed" I would never think of either *limiting myself to this size or even picking them indiscriminately*, because, how is one to tell when they are all mixed in a heap whether one is retaining for next season's planting tubers from a poor root calculated to give a poor return or a typical eightyfold? Just as careful gardeners scrutinise at the season of flowering their strawberry plantations for any blind plants, and there and then grub them up and consign them to the flames so as to avoid any possibility of future stocks becoming barren, so, when potatoes are being lifted, then is the time to select, and only from roots which are above the average both in weight, shape and condition. It must be apparent that under this method of culture best results are attained. This cannot be easily accomplished on farms where potatoes are grown for profit, but there is no reason why this specially selected systematical collection should not be carried out by the private owner of a garden. Last year I planted Scottish seed on land which has been meadow over fifty years, yet, in spite of attacks from wireworms, no one could wish for any better edible potato.—E. E. P.

LACHENALIAS.

SIR,—Lachenalias are among the easiest of bulbous plants to grow. They require no artificial heat whatever. To be kept close to the glass in an unheated greenhouse, from which frost is excluded, is all they require to be grown to perfection. Pendula, a delightful red-coloured Christmas flowerer is the earliest

LACHENALIA PENDULA, THE BLOOMS IN THIS SPECIMEN APPEARED IN NOVEMBER.

of all the species and varieties to bloom. Glaucina closes the season in April. This last is very sweet and is reminiscent of the old-fashioned red cytisus. There are now a large number of hybrids which carry on between these. The public is greatly indebted to the Rev. J. Jacob for his additions to this beautiful group, by such varieties, to mention only a few, as Siam, Monte Carlo, Pega, Rutland, Leiden, etc., also for several unnamed varieties which are to be brought before the public in the near future, some of which promise to eclipse even the best of those now in commerce.—W. MAUGER.

RHODODENDRON NOBLEANUM.

SIR,—If I had referred to Mr. Bean's "Trees and Shrubs," ii, 370, before writing the note about this valuable hybrid in THE GARDEN of the 10th inst., I should have avoided the error of attributing its origin to Messrs. Standish and Noble of the Sunningdale Nursery. The name "Noble" seems to have misled others besides myself, for the error appears in some quite recent books. The truth is that the original cross (which has been frequently repeated elsewhere) between R. caucasicum and R. arboreum was first made by Michael Waterer of Knaphill in 1832. A certain Mr. Noble was so much impressed by the beauty of the first blossoms that Michael named it after him.—HERBERT MAXWELL, *Monreith*.

LABELS AND LABELLING.

SIR,—Some time ago there was a discussion about labelling in THE GARDEN. It would be a great advantage to buyers if nurserymen supplied their plants—especially trees and shrubs—with more or less permanent labels attached to them. The only firm that does this, so far as my experience goes, is a Portuguese one. This nursery uses small, pliable zinc tie-on labels with the name written or stamped thereon in indelible ink. The extra cost of using such labels must be a very small one, while the advantages to the buyer are very considerable. Given all things equal I would personally always deal with a firm that saved me the trouble and anxiety of having immediately to re-label the plant.—COLLINGWOOD INGRAM, *Kent*.

METROSIDEROS IN BRITISH GARDENS.

SIR,—In Mr Haddon's most interesting article on New Zealand plants in THE GARDEN of January 3rd, the statement is made that "great trees of Metrosideros tomentosa and M. robusta ablaze with scarlet blossoms must be a marvellous sight, but M. lucida is the only species likely to succeed at all in most gardens." I should be very interested to know whether this is confirmed by the experience of others who have tried to grow this magnificent family in Cornish or Irish gardens. Here in Cormwall I have come to suppose that M. robusta is an easier plant to grow than M. lucida, although lucida, the Southern Rata, comes from a colder climate and might therefore be expected to be the hardier of the two. With me robusta stands the full blast of the Atlantic gales unhurt, in a position where no other evergreen except Blue Gem veronica, Escallonia macrantha and a few other plants such as Pittosporum crassifolium will survive. It does the same even on the most exposed headlands in the Scillies and thrives on St. Michael's Mount. I believe it does equally well in a good many Irish gardens. But M. lucida is less often a success. I only know of one really fine specimen about here, the one figured in the Rev. A. Boscawen's article in the R.H.S. Journal last January. Here it evidently has need of a more sheltered spot than it has had, and a much more sheltered one than robusta. I think I am right in saying that it is not a success in the Scillies at present.

I write this in the hope that others may be encouraged to try M. robusta, for it is certainly one of the noblest of all flowering trees. As for M. tomentosa, I do not know of anywhere where it is yet established and a success on the mainland, though it thrives amazingly in the Scillies; the best chance, evidently, is to grow it on with winter protection until it is large and has made hard wood and mature leaves, for the young leaves are very sensitive to frost. The plant will stand any amount of wind here as on its native headlands, and it will grow in the barest minimum of soil. I have seen seedlings of it on the face of a rock or in chinks of a wall where one would have supposed nothing but pennywort could survive. When it comes to the end of the food available in one chink, it sends out long red trails of root in search of more food in another chink. So, among various ways in which I am trying it, I have planted it in very stony soil, and also plastered it on to a steep rock face that is curtained with moss and weeds.

Digitized by Google

M. diffusa, the creeping species, must surely be, what Dr. Cockayne calls it, one of the treasures of the New Zealand flora. I know few more delightful plants. In its own country, I believe, it stands full exposure to the sun, but here it seems unable to survive except in permanent shade. Its immature leaves, very sensitive to frost, make a lovely pattern up a tree trunk or a mossy rock; little round leaves like those, say, of a shrubby bog pimpernel (Anagallis tenella). The mature leaves are more like those of Eugenia Ugni, the edible myrtle. And the flowers, are umbels of rose-scarlet brushes, each brush gold-tipped.—Z.

WINTER WORK AND PLANTING

BY EDWIN BECKETT.

IT always seems to me that someone made a mistake about the official commencement of the winter season to cause it to arrive at the end of December and last until March, for the period which we designate by that name certainly appeals to one as being half over by the time Christmas arrives. It is, therefore, necessary to adjust one's perspective somewhat when considering the work that can be accomplished during the winter season. It may appear a quiet time, but, in a good garden, where the working details are always going with a swing, there is a great deal that can be accomplished during the dull days of winter, in preparation for the coming spring season of busy activities.

Probably the prime occupation is the ground preparation work by means of trenching, which should be carried out during the days of late autumn and early winter, on the lighter soils, but on the heavier grounds should be deferred until the days of later winter so as to prevent the climatic influences, notably heavy rains, from beating down the soil and forming it into a sticky, tenacious mass once again. This year it is a very important point, for the rains that we have recently experienced have been heavy enough to pack practically any trenched ground. Open dry weather periods, and especially frosty spells, arriving before the desirable trenching time, should be fully utilised for wheeling into position the manure which is to be incorporated at the time of trenching, and in speaking of these two items, I would urge the real importance of properly manuring ground, for vegetables cannot be expected to thrive in soil that is deficient in their proper foods, and another fact to be emphasised is the importance of real deep trenching: by this is meant getting well into the subsoil and bringing it up to the surface, so as to rotate the soil from period to period, affording that below the surface one year the chance of being acted upon by light and air the following one, and doing this work by trenching will afford a properly worked root run, well down, so that the plant can work to find its food—always a beneficial factor in a plant's life.

Probably the operation that calls for as careful review at this time of the year as the foregoing is the question of planting. We will consider this general question under three separate sections: Herbaceous Plants, Trees and Shrubs, and Fruit Trees. Dealing with the first group, the winter period does not affect this to so great an extent, for the aim should be to arrange for this work in the early or middle part of autumn, rearranging or replanting the borders soon after the dormant period of the plants is arrived at. Borders require replanting about every third year, and this should be thoroughly carried out, not doing it by half-measures. The plants should all be lifted and heeled in on a spare piece of ground, the border then trenched, incorporating food in the shape of spent manure, leaf-soil, etc. Do not employ rich food for the majority of plants, as this will only encourage rampant growth, with the possibility of adversely affecting flowering. Here it is necessary to add a caution as to one or two groups of plants. Peonies, hellebores (of the Christmas rose section) and iris require separate treatment, the correct time for moving these being late summer, owing to their curious rooting characteristics. If, for any reason, this replanting work was deferred at the autumn period, and it is still required to be done, then it should be held over now until the late winter period, arranging to do it then, during open weather, just prior to the plants becoming active for commencing their early spring growth.

In the tree and shrub plantations, open weather in winter is a very suitable time for effecting the planting and transplanting of all the deciduous items, but go steady about the evergreen sorts, for some of these strongly resent being shifted at inopportune times. Among the latter are such as yews, conifers, and hollies. These plants shed their foliage, though some folk seem to think that they do not, and as transference from one place to another gives their growth a greater or lesser check, then the aim should be to move them at such time as their growth is at its highest activity, and this may be considered as at the period when the plant is thrusting forth new foliage and growth. If the moving is accomplished then, any check that the plants receive which causes old foliage to be affected, is overcome by the young healthy foliage ridding the plant of its dying leaves, and, root activity also being present, the moved plant is the more likely to get over its handling and make steady progress. If this work can be carried out in showery weather, so much the better, for the overhead moisture greatly assists the plant by keeping the top growth in good moist condition, a part where it requires it even more than at the root.

Before moving trees or shrubs, have, as far as possible, holes prepared for their reception, the bottoms of which should be well broken up; but the excavation should not be too deep, for deep planting is very harmful, and a frequent cause of plants taking on a sickly appearance, and oftentimes of their dying off. Soil and manure should never be placed round the stem of a fruit tree or flowering tree such as a thorn, crab, etc., as it is a grievous and most harmful habit.

Heavy topped subjects should be supported by stout poles or stakes, to obviate the possibility of further disturbance to the roots during heavy winds, such as would be caused by the swaying of the top-burden, and even to prevent uprooting during gales.

The question of fruit trees was left to the last because, even though it may be considered a trifle late for such planting work, yet even now much can be done, and it is desirable to force home the need of first-class work in this case. It is as well to consider one's trees from the economic standpoint, and where a tree, either wall, orchard, or under glass, has proved a consistent failure under good treatment, then no mercy should be shown it, and if not young enough for the system of "crown grafting," it should be removed from its place and replaced by another that will give its yield. Planting should be done in careful manner, and if the ground is heavy and liable to waterlog, then the trees should be planted on a slight, artificially formed mound, above the surrounding level. This has been pointedly illustrated on the heavy soils during the recent flooding weather, where ground has been saturated by the heavy rains, and one has had the pleasure of seeing the trees on their mounds, standing comparatively dry, like island sites, in the midst of the surrounding water-strewn level ground. Again it should be added, "stake thoroughly," for fruit trees, above all, require this very necessary support.

There are many more items that can occupy the busy and attentive gardener during the winter period, such as the preparation of sites for hedges where required, for these, too, benefit from the prior careful preparation of the soil; the formation of new gravel walks, and the setting in of drainage where the formation of pools of water denotes that it is required, or the attention to drains that already exist if this warning sign is exhibited; and the final word is, perhaps, again necessary: to watch newly planted stuff after frosts, to make sure that the soil has not been disturbed and roots exposed thereby, and to suggest the placing in position of protective material, where convenient to do so, around such plants, before the arrival of frost, if such threatens. It is most important that the roots should not be exposed, otherwise the plants receive a severe check, which in many cases is never got over.

SIMPLE GARDENING

DIGGING SHRUBBERIES AND HERBACEOUS BORDERS.

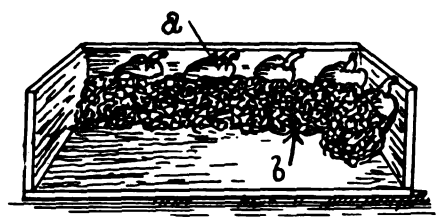
OWING to the long spell of wet weather it was not possible to deal with this work satisfactorily before Christmas. Shrubbery borders should receive attention first, now the weather is drier, especially in gardens where the soil is of a stiff, clayey nature. The owners, in these circumstances, need not worry because the digging could not be done at an earlier date, as much better results will follow if the soil is turned over now. In the case of new shrubberies where large deciduous trees do not cast their leaves so that the latter collect under the shrubs, the soil should be dug and left in a lumpy condition until the month of April. The lumps will crumble at the touch of the rake then and the border will look clean and fresh during the greater part of the summer. No digging should be done among shrubs where it would interfere with the roots of the latter. In the case of old shrubberies the actual digging should be confined to the outer edges of them, and if partly rotted tree leaves are collected round the stems of the plants they should be neatly spread out and covered with some loose soil; only a small quantity is needed to keep the leaves in position till they are rotted, then the shrubs will benefit. It can now be clearly seen how much ground the bulbs occupy in herbaceous borders and the workman can avoid doing any damage to them; also to many herbaceous plants which are pushing up new shoots. A judicious application of rotted manure would do a lot of good to the plants.

PARSNIPS AND BROAD BEANS.

Parsnip seeds are slow in germinating. They are sown at an early date, too, when the soil is cold, so due allowance should be made, and early germination cannot be expected. Of course, soils vary, dark coloured ones are warmer than light ones, but if the latter are of a sandy nature or otherwise very porous, they become warm much sooner than the dark heavy loams. The parsnip requires a long time in which to grow, and full-sized roots can only be produced by the timely sowing of seeds in soil found to be in a suitable condition at the time. No trouble will be met with on sandy soils, but there may be on heavy ones. The latter should be treated as follows: if the ground has been deeply dug or trenched the surface portion only will need preparation. Fork up the top 6ins. or so on a fine day, doing this early in the morning, about noon use the iron-toothed rake to reduce the lumps to a powdery condition and then open drills 18ins. apart and nearly 2ins. deep. Scatter some wood ashes in the drills, then drop a few seeds, about 9ins. apart, in isolated clusters, not generally along the entire drill. Scatter some old, dry soil on the seeds before finally filling the drills with some of the original soil. Rake the surface in the same direction that the drills run and do not tread on the surface more than can be avoided. The earliest broad beans result from an autumn sowing, of course, but quite early gatherings are obtained from plants raised from late winter sowings. I advise readers to try the following method. Instead of opening drills, after the ground is prepared, and sowing double lines of seeds, plant the seeds with a hand trowel 2ins. deep in single rows 18ins. apart. Every plant will grow sturdily and bear heavy crops. Sow on the level ground.

HOW TO GROW EARLY POTATOES IN WARM BORDERS.

Potatoes will be dear during the spring owing to the ravages of disease last year and the resultant scarcity. Those cultivators who possess "sets" of early varieties in sufficient numbers to permit of experiment, should make a selection of some of the most forward tubers



and place them in a box about 6ins. deep; three-parts of the tubers being buried in leaf-soil or fine soil from flower pots, such as will encourage the growth of roots quickly. The boxes may be placed in a frame or a greenhouse and the tubers sprinkled with tepid water several times each week. There should be a space of 3ins. between the tubers so that they can be lifted in due time with the soil adhering to the new roots. In the meantime, any warm border outside, such as one at the foot of a wall or fence, or one on a sloping bank facing south, should be prepared for the growing plants. It is important that the soil be made as fine as possible. When ready transfer the plants—growing sets—to the new border, planting them 2ins. deep, and provide rough litter, leaves or branches for covering if frosts come. New potatoes will be available one month earlier than in the ordinary way of growing them. Old heaps of rotting leaves and soil rubbish may be levelled and an early crop of potatoes grown on them. I have so grown them for many years. Potatoes will thrive in pure leaf-soil. At *a* the tubers are shown partly buried in soil *b*; *c* shows roots and soil, *d* haulm growing and *e* the principal runner roots. All these must be taken care of.

PLANTING IVIES.

Ivies are grown throughout the country, more generally than any other climbing plant, if we include those growing in a wild or semi-wild state. Perhaps it is because the plants are so common that they are so much neglected. In a wild garden or plantation the ivy is not trained or cultivated; in a garden it should be well treated and looked after, then the plants are objects of beauty as well as being useful. In a Lancashire garden, some years ago, various kinds of plants were tried as edgings to a long carriage drive leading under large trees growing on both sides of it. All these plants failed; then ivy was tried. I carried out the work and, in doing so, mixed old lime rubble freely with the soil. The plants were pegged down, grew satisfactorily and formed a very pleasing edging which entailed little trouble to keep in order.

The plants are useful for clothing walls, old buildings and banks, but if a careful selection be made the results may be much more pleasing than they are. In every case where the soil is deficient in lime some old mortar rubble should be added. A collection of these plants trained to stumps in some suitable recess in the garden is very interesting. Silver and golden-leaved varieties should predominate with a judicious mixing of green-leaved ones to show up all to the best advantage.

GLOXINIAS AND TUBEROUS BEGONIAS

Sometimes the old corms are kept in their flowering pots through the winter and very frequently numbers of corms rot, especially if they have been placed too near to the hot-water pipes under stages. Others are wintered in boxes and these are often the best corms at this season. It is now time to subject the corms to a gentle heat and some moisture. It is very interesting to watch the new shoots grow around the hollow cup-like surface of the old corm. Of course, there is a right way to start the new growths, and the amateur who wishes to do this should procure several shallow boxes and place a thin layer of sifted leaf-soil in the bottom of each; then press the corms gently into it and fill up the spaces between, also with leaf-soil, level with the crowns, but not burying the latter. Apply water through a rosed watering can once; more water in this form will not be needed till the corms are potted separately. Semi-darkness will not be harmful at first, but after the stage when the new shoots are 1in. long full daylight is essential at this season.

GEORGE GARNER.

BOOK REVIEW

ONE of the most comprehensive attempts at a real biology of the flowering plants has just come into our hands. This volume is a valuable contribution to a series of interesting biologic works dealing with the various branches of natural science. The present volume is "The Biology of Flowering Plants," by Dr. MacGregor Skene, Lecturer in Plant Physiology at Aberdeen University (Sidgwick and Jackson, Limited, London, price 16s. net). Like its predecessors, it is a genuine attempt to correlate all the scientific facts, morphological and physiological, which are known at the present time regarding the flowering plants and their relation to their environmental conditions. The plant is treated as an indivisible entity, a living unit, which if divided would perish—which view is, naturally, a purely biologic one. The author, in addition, presents to the reader the more modern idea of biology—its intimate association and close linkage with the function of the organism *in toto* depending on the proper functioning of each of its component parts—that is, he approaches it from the purely physiological side. Undoubtedly it is the outward expression of the view which has been looming darkly on the botanical horizon for the last twenty years. In these days the physiologist finds himself at his zenith, having by carefully compiled and accurate experimental data deposed the old *régime* of botanists who were essentially morphologists—the men who held to the far-reaching theories of last century. But he is rather apt to forget the pioneer work carried out, often laboriously, by the older botanists, in these days of increased specialisation, when the subject has been split up into so many branches, each bristling with unforeseen and difficult corners requiring careful negotiation. The great argument against the older workers was that they had no experimental evidence by which to substantiate their theories, and consequently the age of experiment is with us now in many cases proving how entirely false these old ideas were. This may seem to lead nowhere, least of all to a criticism of this book, yet it has a bearing which will be realised by those who read it. The volume, to be a biology, is perhaps too physiological, although it is realised it is a moot point how much constitutes a sufficient amount on which to base biologic knowledge. More space might have been devoted to the study of structure and its intimate correlation with function, which is so well pointed by Haberlandt in his "Physiological Plant Anatomy," and also by Goebel. Some day we will witness the inevitable reactionary swing of the pendulum to extreme morphology, and while such a thing is to be deprecated, it is bound to happen if the picture be entirely obscured by a physiological view. The volume is valuable in so far as it tends to bring out the general trend of biology, and as such it is strongly recommended. The facts are set forth clearly and concisely with a genuine aim to show their relationships. The many scattered threads of the subject are gathered together and woven into a delightful and readable book which gives the reader a clear insight into the wide confines of botanical science. Such a volume is to be welcomed. It serves as a check to over-specialisation in any one branch. The links which bind these separate studies are clearly shown, and also how these apparently isolated facts all fit into their appointed places, rendering the story more complete as time goes on. The subject matter is treated under six heads, viz., (i) The Soil and the Absorption of Water and Salts; (ii) Assimilation and Transpiration, which leads on in natural sequence to (iii) Special Modes of Nutrition as found in Saprophytes, Parasites, and Symbiotic Relationships; (iv) Mechanical Problems; (v) an interesting chapter on Reproduction and Dispersal; (vi) Development, wherein are discussed such controversial questions as germination, conditions and mode of growth, and the vegetative and reproductive phases. One of the valued assets of the book is the very complete bibliography of all the literature to which reference has been made in the text. It is a most extensive and broad list, and shows the care and thought the author has given to the selecting of his facts and their compilation. As a work of reference the volume will prove of the greatest possible assistance, there being over 500 references to literature. Such a compilation of scientific facts entirely untrammelled from a mass of unnecessary detail is worthy of the highest praise, because it is not there without much effort, laborious toil and thought. There are numerous drawings in line throughout the pages and many of these are original and well executed. To the botanist it is recommended as worthy of a place on his shelves; while those more interested in general horticulture, although perhaps too advanced in some aspects, will find much to interest and instruct them in the author's presentation of such a wide subject. G. C. T.

Trials at Wisley.—The Royal Horticultural Society will carry out trials at Wisley this season as follows: Potatoes (second early varieties only, but including varieties suitable for salads), turnips and garden swedes, peas (early varieties only). Varieties for trial should reach the Director, R.H.S. Gardens, Wisley, Ripley, Surrey, on or before January 31st, 1925. The necessary entry forms may be obtained on application to the Director.

The Sale of Seed Potatoes.—A firm of Scottish seed potato merchants was recently convicted of an offence under the Seeds Act, 1920, in respect of the sale of a consignment of 2 tons of Sharpe's Express seed potatoes with an incorrect description of the variety. The Seeds Act, 1920, and the Seeds Regulations, 1922, require, in the case of a sale of seed potatoes, that the seller shall make a statement in writing to the purchaser at, or before, the time of sale or delivery, containing particulars as to the class, variety, size and dressing of the potatoes. The name of the variety in this connection is not taken to be incorrectly stated if it is true in respect of 97 per cent. of the total quantity sold. In the case in question the seed potatoes were estimated to have contained approximately 30 per cent. of "rogues." The defendants pleaded guilty and a fine of £5 was imposed. A pamphlet (Form No. A, 64/H.D.) containing a summary of the Wart Disease of Potatoes Order, 1923, and of the Seeds Act, 1920, and the Seeds Regulations, 1922, so far as they affect the sale of seed potatoes, may be obtained free of charge on application to the Secretary, Ministry of Agriculture and Fisheries, 10, Whitehall Place, S.W.1.

Importation of Bulbs into Switzerland.—Instances have been brought to the notice of the Ministry of Agriculture and Fisheries during the last few months, in which consignments of bulbs from this country have been delayed entry into Switzerland owing, it is stated, to the absence of a permit from the Swiss authorities. The Ministry is informed that consignments of bulbs as well as of other plants must be accompanied by the consignor's declaration and official certificate in the form prescribed in the Phylloxera Convention, and a translations of these documents into French, German or Italian must be furnished. The sworn declaration accepted by some countries as sufficient compliance with the requirements of the Phylloxera Convention is not accepted by the Swiss authorities. In the absence of such declaration and certificate, the consignment will be admitted only after a permit for its importation has been obtained by the Swiss importer from the Federal Department of Public Economy. The issue of the necessary certificate by the Ministry involves the examination of the premises on which the bulbs or plants were grown, and a fee of 2 guineas is payable in respect of such inspection. After the premises have been examined and passed, any number of certificates can be issued during the following twelve months, after which a further examination will be necessary. A charge of 1s. is made for each certificate issued.

Prohibition of Importation of Potatoes from the United States of America.—The 1924 crop of potatoes in the United States of America has been so plentiful that export markets for the surplus are being sought and small quantities have already been sent to this country. Unfortunately, the potato fields over large areas of the States are infested with the destructive Colorado beetle—a pest of which the importation into this country must be guarded against as far as possible. It will be remembered that the Colorado beetle established itself during recent years in a small district of France and the Ministry of Agriculture and Fisheries then felt compelled to prohibit by Order the importation of potatoes from that area, for so long as the pest exists. The importation of potatoes from the United States is attended with equal risks, and the Ministry feels it necessary similarly to exercise its powers under the Destructive Insects and Pests Acts and to prohibit the importation of potatoes from the United States of America. An Order entitled "The Colorado Beetle Order of 1924" has accordingly been issued, under which the importation into England and Wales of potatoes grown in the United States is prohibited. The Order comes into operation immediately, but provision is made for the admission of any consignments that may already have been shipped.

CATALOGUES RECEIVED.

We have pleasure in bringing to the notice of our readers the New Season's Catalogue of Messrs. Fidler and Sons, Reading. Although not published on a grandiose scale, it is comprehensive and includes all varieties of real practical value and worthy of cultivation, and should prove of service to the amateur when he comes to make his selection of flower and vegetable seeds.

A Birmingham firm, Messrs. Simpson and Sons, also present their 1925 Seed List. Much useful information is given throughout its pages, and a unique feature is the special cultural directions which are given to growers of potatoes and strong reasons why Scotch seed should be used. The culture of sweet peas is also dealt with concisely but yet accurately. Two pages are devoted to Sweet Pea Colour Schemes for table and garden decoration, while another is given over to a chat about varieties. These have been written, respectively, by Messrs. R. F. Felton and Norman Lambert, and should prove of the utmost value and interest to the raiser of sweet peas.

Other seed catalogues which have come to hand are those of Messrs. Daniels, Wymondham, Norfolk (Vegetable and Flower Seeds), and Messrs. Hawkins, 408, King's Road, Chelsea (Vegetable and Flower Seeds), with a useful section devoted to garden tools and accessories.

We have much pleasure in bringing to the notice of all growers the Annual Wholesale Seed Catalogue of Messrs. Cooper, Taber and Co., Limited, 90–92, Southwark Street, London, S.E.1. It is a comprehensive list and includes several novelties and specialities for the year. It is a list all growers should possess. We understand that they are also publishing a retail catalogue which can be had on application.

VOL. LXXXIX.—No. 2777. FEBRUARY 7, 1925

Price Threepence. Yearly Subscription, Inland, 17s. 4d.; Foreign, 17s. 4d. Registered at the General Post Office as a Newspaper and for Canadian Magazine Post.
Editorial Offices: 20, TAVISTOCK STREET, COVENT GARDEN, W.C.2. *Offices for Advertisements:* 6–11, SOUTHAMPTON STREET, STRAND, W.C.2.
Entered as Second-class Matter at the New York, N.Y., Post Office.

THE BEST CONTRIBUTION TO OUR PAGES.

LAST April I announced that THE GARDEN would give an order for £5 on any advertiser in our pages as a prize to the amateur contributor who sent in the best note during the year. This year the prize is awarded to Mr. R. B. Cooke, Kilbryde, Corbridge-on-Tyne, who sent in a most excellent note on the hardiness of shrubs on Tyneside, which was published in THE GARDEN, November 29, 1924. The information given in this note is of the greatest use to all gardeners on the East Coast and in the North. The collection of shrubs mentioned, although not large in numbers, comes from every part of the world, and the information given about them is short and very much to the point.

FORCED FLOWERS.

At this time of year most of the flowers used in house decoration are forced, and many that are bought in the shops are not only vigorously forced, but have to travel long distances to market. I bought a bunch of tulips the other day and had to keep them in a vase in my office until I took them home at night. By the end of the day they were so flagged that they had flopped right over on their long stems. On reaching home I cut an inch or so off the stems and slitting them placed them in warm water. In a quarter of an hour they were standing straight. Now this is not a note to teach the readers of THE GARDEN what they all know, but to point out a fact that is not so universally recognised, and that is that forced flowers will last double the length of time if the water is changed regularly every day, particularly if the water is not taken straight out of the tap. The physiological reason for this I do not know, but it is a fact that is worth noting. I have kept these tulips in a hot room for over a week and they are nearly as fresh as on the day I bought them.

OSMANTHUS DELAVAYI.

I have drawn the attention of our readers several times before to the great attractions of Osmanthus Delavayi and without hesitation I do so again, for it is not spreading through the country with the speed that it should. People are always commenting on the extraordinary way in which two trees, rare in their day, Sequoia gigantea and Araucaria imbricata, were planted in almost every garden. The plants were insufficiently advertised, if they were advertised at all; yet they were quickly scattered throughout the country and seemed to catch the eye of the public more easily than they do now. Mr. Bean speaks of Osmanthus Delavayi as one of the best of the newer Chinese shrubs. It is hardy, easy to grow and easy to propagate; it is neat in its growth, charming in bloom, with its clusters of small white tubular flowers and with the added advantage that they are fragrant. It grows equally well as a graceful bush in the open, against a wall, or as a hedge. And yet with all these attractions it has not caught on as it should. The popularity of plants in our gardens is difficult to explain, why one plant will be scattered broadcast in two or three years and another, just as attractive and as easy to propagate, will hang fire. Osmanthus Delavayi illustrates a case in point which seems contrary to the old proverb which says: "Good wine needs no bush" unfortunately, however, its goodness is taking a long time to be discovered despite the fact that it has been brought to the notice of all shrub lovers many times before. It is to be hoped that its merits will soon be realised and that it will gradually take up its rightful position as one of the most outstanding shrubs in our gardens which has come from the Far East.

OUR SEED NUMBER.

The next issue of THE GARDEN will be devoted to annuals. I am sure that this number will be of great use to our readers, because annuals, from their nature, are constantly changing in popularity and it is exceedingly difficult for the garden lover to keep in touch with the latest developments among what, after all, are still the backbone of our gardens. Among special articles will be "Some Favourite Annuals," dealing particularly with clarkias, godetias, stocks and China asters; an article devoted to zinnias, which make such violent splashes of colour even on the dullest day; another on "Some of the More Uncommon Annuals" deals with such as are not often enough seen in our gardens. Then there is a note on the novelties in the sweet pea world which proves what strides this most popular of annuals is now making towards refinement. Another interesting contribution is that on "Annuals for the Rock Garden," which shows how the rock garden can be assisted during the summer months, which is usually its off season. Then there is an article on colour in the garden from an artist's point of view. And so the tale goes on. E. H. M. C.

MECONOPSIS in a SCOTTISH GARDEN

BY A. H. HARLEY.

THE AUTHOR HAS BEEN EXCEEDINGLY SUCCESSFUL IN GROWING THIS FASCINATING GENUS AS IS SEEN BY THE ILLUSTRATIONS, WHICH ARE ALL OF PLANTS GROWING IN HIS GARDEN.

IT is surprising that so few people grow these beautiful flowers. Although most of the species are biennials, they are as easily grown as the majority of annuals.

In the drier climatic conditions in the south some difficulty may be experienced in growing these meconopsis, but in Scotland, especially in Perthshire, and farther north where the climate is more moist, there should be no difficulty in growing them.

My plants have no protection whatever and stand hard frosts and wet weather during the winter better than most biennials. I sow the seed about the end of February in heat, in pots, on a surface made fairly firm. They germinate very freely in a short time, and after having produced a true leaf are pricked off into boxes in a compost of loam, leaf-mould and sand, and are kept in slight heat till established. The boxes are then placed in a cold frame to harden the plants off, after which they are planted out in May.

Meconopsis, having tap roots, must not be allowed to stand too long in the boxes or they will get stunted and never make satisfactory plants. They want as long a growing season as possible before flowering. Most of the plants will flower the following year; but those that do not, make great growth and throw up a large flower spike the third year and generally produce the finest flowers. Meconopsis Wallichii and M. paniculata bear handsome persistent foliage during the winter in distinction to M. simplicifolia, which forms a large resting bud.

The other species mentioned die down in late autumn and show no sign of growth during the winter. Precaution, therefore, must be taken that they are not disturbed by any movement of the soil round about them. In cases where the soil is poor or inclined to be dry, a liberal addition of well rotted manure is beneficial; this should be placed well beneath the surface of the soil.

Those which are in fairly common cultivation are:

MECONOPSIS INTEGRIFOLIA, of which I have two forms. The illustration shows the large-flowered form, and one of my plants last year had thirty-eight flowers on the one plant. The other form I have has much smaller flowers, more cup-shaped; this sets very little seed, whereas the large-flowered form seeds very freely. These meconopsis come into flower in April and keep on flowering until the end of May; the cold weather we sometimes get during these months does not affect the flowers. This, I consider, the best of the early-flowering species, deserving of being grown in moist ground in any garden. The flowers on well grown plants are sometimes 7ins. in diameter or even more, being of a light yellow colour, and are produced in very large numbers. The foliage is dense, in the form of a rosette, from which the inflorescence grows up in early spring. I have a form growing under the name of M. brevistylum, but at present I cannot detect any difference between this plant and integrifolia. This species is a native of western China.

M. SIMPLICIFOLIA (Bailey's form).—The blossoms of this species spring straight from the neck of the stock on a single stem, and are quite the most gorgeous of the single-bloomed meconopsis, with flowers of dazzling sky blue, the colour being a darker blue in the opening buds on the back of the petals. This is a monocarpic form collected by Major Bailey in 1913, on the borders of Tibet, and first raised in the Edinburgh Botanic Garden. It is a very popular meconopsis and under cultivation appears to be quite distinct from the type plant of the species. It is also a free seeder.

M. SIMPLICIFOLIA.—This species, with me, is perennial, and some of my plants have been in cultivation for the last six years and have flowered and produced seed annually on stalks which do not lengthen out as in Bailey's form. The flowers are purple and not nearly so pretty as Bailey's form. These two forms flower in May and June.

M. GRANDIS.—This species is also a perennial and I consider it one of the most showy in cultivation. In my

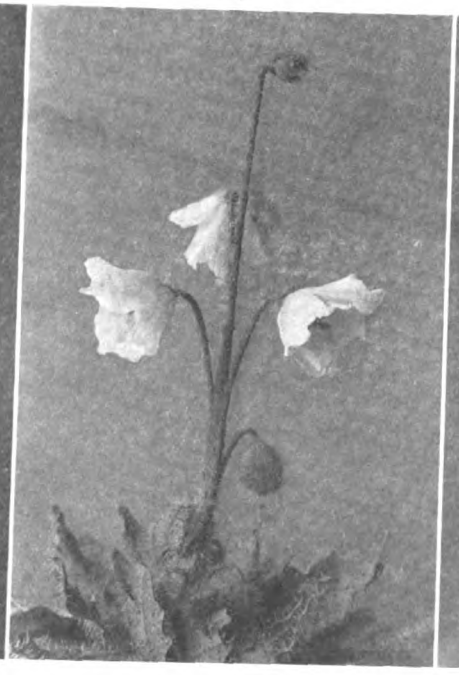
THE BEST OF THE EARLY FLOWERING SPECIES, M. INTEGRIFOLIA.



A WHITE FORM OF M PRATTII, M. PRATTII ALBA.

A ROBUST SPECIES WITH YELLOW FLOWERS, M. PANICULATA.

experience this species has proved itself a shy seeder, and is in consequence very seldom seen in our gardens. It is a good grower and, with care, those who possess plants are not likely to lose it. My plants have set no seed during the last three years, although the blooms have been hand fertilised. The flowers vary in colour from rich violet and clear blue veined with violet to duller slatey tones, 4ins. to 5ins. across, and are borne on stems over 3ft. high. Flowers in June.

M. PANICULATA.—This species is a robust grower, 5ft. to 6ft. high, with stout stems and has pendent yellow flowers. The stems have foliage with yellowish hairs. It commences to flower at the top, flowering from apex to base of stem. This species makes an excellent plant for growing in a rhododendron bed, coming into flower after the rhododendron blooms are past. It will continue flowering for four or five weeks, coming into flower with me in August. This species is biennial and seeds very freely.

M. WALLICHII.—This is a very robust grower as well as one of the most desirable, and one that is probably most often seen in gardens. Well grown plants should attain a height of about 6ft., commencing to flower at the apex, and the lower flowers opening over a period of six to eight weeks. The flowers are very variable in colour, ranging from pale blue through all the shades to pure white, and from slate to claret colour. The most attractive, I consider, are those having light blue tints. I have several times sown seed saved from the white forms, but the resultant seedlings show great variations in tints of the flowers, and very few come true to the parent white. For the last few years I have sown seed saved from the best coloured plants and have got improved colours, but up to the present I find it impossible to get rid of the slates and clarets. Now I seldom trouble to sow seed of this species in pots. From the number of plants growing in my garden, I secure a large quantity of seed in the autumn. This seed, in the following spring, I scatter, preferably in beds where rhododendrons are growing. Here it germinates very readily, and in the autumn this method gives me a large number of sturdy, healthy plants, which I transplant into positions where they are wanted to bloom the following summer. This species produces its blooms in August and September, and is the latest to flower; but, unfortunately, is also a biennial.

M. PRATTII.—Grows 15ins. to 18ins. high; variable in colour, some of the flowers are a pretty shade of blue and others showing purple tints. The stems, foliage and seed pods are very prickly. Prattii, like most of the other species, is a good grower and reproduces itself in quantity from self-sown seedlings if the soil is not disturbed by hoeing or raking, and is allowed to become fairly firm on the surface upon which the seed falls. It is a native of western

THE "HAREBELL POPPY" M. QUINTUPLI NERVA, WITH LAVENDER BLUE FLOWERS.

Digitized by Google

China. I have a white form of Prattii, which, among meconopsis, stands out very conspicuously from the other members of the genus. The flowers of this are pure white and come true from seed. Both flower in August, and like the type, are biennials.

M. RUDIS is very similar to Prattii, with light clear blue flowers, but can be distinguished from Prattii by the black spines on the leaves. It flowers at the same time as Prattii and is biennial. I have another species under the name of rigidiscula. It is very like Prattii, but grows taller, over 2ft. high, and is very prickly to handle. Flowers same time as Prattii and is also a biennial.

M. QUINTUPLINERVIA, has single bell-shaped, nodding flowers of lavender blue, produced singly on slender stems about 18ins. high. The late Mr. Farrer gave it the name of the "Harebell Poppy," and considered it a "gracious and lovely thing." It is a native of the Kansu-Tibet border, at an elevation of 9,000ft. to 13,000ft., where it is found in great profusion in the alpine turf. In cultivation this is a very pretty species, but perhaps not quite so showy as some of the others, but, fortunately, is of a perennial character, and with me it increases very quickly, and single plants I got three years ago are now forming a clump of 18ins. diameter. I find this species does not require such a damp position as that required by Wallichii, but seems to prefer a well drained stony soil. This species blooms during May and sets seed, but not with the profusion of other species. Compared with others, the capsule is rather small and therefore does not contain a large quantity of seed. Seedlings I have raised from my plants vary in size of bloom and shade of colour, and if seed is sown in early spring I find some of the seedlings flower the same year.

M. LATIFOLIA.—This is a native of Sikkim and Bhutan, where it grows at a high elevation. This is one of the few meconopsis that like a dry situation, and I consider it one of the most beautiful species I have. The flowers are a pretty shade of Cambridge blue, and are very attractive. It has been called the Kashmir Poppy. It seeds so freely that self-sown plants are often found springing in the crevices of the rock garden, and these often produce the finest plants. In this position it develops stout stems and large numbers of flowers on same. It commences to flower at the end of June, continuing over a considerable period. I find it does not succeed in the damp positions that are suitable for many other species. My plants have been growing in the same situation for the last five years, a corner of the rock garden where it seeds very freely and sows itself. This species is usually biennial, but individual plants may not flower until the third year, in which case they are exceptionally strong specimens and the flowering stem may reach the height of about 30ins. and produce flowers in great abundance.

THE CONSTRUCTION OF A LAWN

BY REGINALD BEALE.

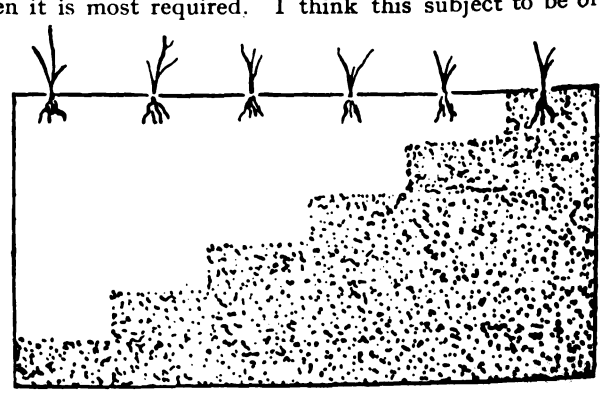
IT is no easy matter to produce a really first-class lawn, nor is it simple to explain in black and white how it can be done and at the same time keep within the limits of a series of short articles. From my experience the best results are obtained when the work is ordered in such a way that the ground is ready for sowing by mid-August. The soil at this time of the year is at its maximum warmth, and if the ground is ready the seed can be sown at the selected moment, and that is as soon as the summer definitely breaks. Seed sown under these conditions should germinate in less than a week, and the warm autumn rains should make it grow so rapidly that it will require mowing several times and be well established before the winter sets in. It will also stand a better chance to smother out any weeds that may be lying dormant in the soil when they appear in the spring.

Equally good results can be obtained in the spring, provided that it is open and genial, sowing the seed from March to May according to the season. If the weather is favourable, with sunshine, showers and warm still nights, the young grass will simply jump out of the ground and quickly form a turf. As, however, we frequently experience a month or six weeks of cold parching wind at this time of the year, there is always a chance of trouble, because grass seed will not germinate evenly or young grass thrive under such conditions. If the season is cold or late, the soil temperature will be low, so a slow patchy germination may be expected and weeds will certainly cause trouble.

A lawn, if sown between the middle of August and the end of September, should be fit for use by the end of the following spring. It can be sown later, up to mid October, but every day's delay slows up the germination and adds to the risk of failure. A spring sown lawn, given favourable weather, should be fit for moderate use by the end of the summer.

The construction of a new lawn can roughly be divided into five operations—digging, manuring, preparing the seed bed, seeding and after-treatment. As a general rule the ground should be dug one spit deep, turning the soil well over and at the same time breaking up the large clods and picking out any stones, weeds, roots and other rubbish the soil may contain. Grass being a shallow rooting plant makes it quite unnecessary to work the soil to a greater depth, unless the old turf is to be buried, in which case it should be trenched two spits deep. A pleasure lawn need not be levelled horizontally unless it is required for games. This question will be dealt with later on in the construction of a lawn tennis court. At this point drainage should be considered and, if necessary, a system of drains put in. Should the soil be too light and poor or too heavy to carry a fine, close turf, as is sometimes the case when dealing with very sandy or heavy clay soils, an effort should be made to procure sufficient light loamy soil to cover the site to the depth of at least 2ins. If the soil is deficient in lime, it should be applied in the form of pulverised chalk at the rate of 1lb. to the square yard and worked in.

Manuring is the next and most important operation. I cannot too strongly recommend my readers to give it very careful thought, because no matter how good the soil may be reputed, the results will be both better and quicker if it is well manured. The best general manure to use is fresh peat moss, stable manure, old well rotted short straw manure and Carter's Complete Grass Fertiliser. The peat moss and rotted straw manure should be spread over the surface at the rate of one load to every 100 square yards of the surface, and forked or dug in in such a way that the bulk of it remains within 2ins. or 3ins. of the surface. If the Complete Grass Fertiliser is used, broadcast it over the surface at the rate of 2 oz. to the square yard and rake it in. Some maintain that manure, if used, should be buried at least 6ins. deep, while others hold that it should not be used at all for fear of making the surface hollow and the grass grow coarse and rank. I have proved over and over again that the closer the manure is kept to the surface the better and quicker are the results, because the young grass plants can reach it quickly and receive the desired food when it is most required. I think this subject to be of such



importance that I do not apologise for stressing it by means of a sketch. The shaded part is an effort to represent the manure mixed with the soil varying in depth from nothing to 6ins.

Digitized by Google

Which of the little plants are likely to grow fastest and thrive best, those that have rooted straight into it or those that have to struggle down several inches before they reach it? There is no fear of the quantity recommended making the soil hollow if it is carefully mixed with the soil, and the suggestion that it makes grass grow coarse and rank is a fallacy. It may, and I hope will, make the grass grow robustly for a time, but the mowing machine will soon cure that. If a mixture of coarse grasses is sown, a coarse turf will result; but if only the very finest grasses are used, a turf of the finest quality will be produced.

Prepare the seed bed by breaking up the clods, removing all large stones and weed roots with an iron-toothed rake; then roll, rake and tread the ground until the surface becomes quite firm, fine and true, and when walked upon hardly shows the imprint of the foot. Too much care cannot be given to this part of the work, and if it is gone over two or three times, whether it wants it or not, so much the better.

In order to produce a close, dense turf of the finest quality within a year from the date of sowing, given normal weather conditions, the seed should be sown at the standard rate of 1oz. to the square yard, or at the maximum rate of 2oz. when more certain and earlier results are desired. It goes without saying that if the seed is sown thickly, the ground will be covered almost from the start with a thick mat composed of a multitude of little grass plants, which, being mutually protecting, will daily increase in strength and form a close matted sward (see Fig. A) and to a great extent smother the weeds, which will surely be present in quantity. If, on the other hand, it is sown thinly, a thin crop is produced (see Fig. B) which may be damaged or destroyed by a short burst of hot sun or cold wind. The weeds will have an equal chance with the grass,

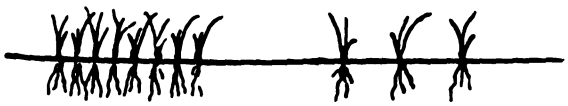


Fig. A. Fig. B.

and in any case one has to wait for the young grass plants to grow and spread until they intermingle with one another, mat and form a turf.

Sow the seed on the raked surface, choosing a calm, dry day, otherwise much of the seed may be blown away and lost, or, should the soil be wet, it will stick to the operator's boots and so spoil the finish. In order to obtain an even distribution divide the ground into strips about 3ft. wide by means of pegs and string and the seed into as many portions as there are divisions. Sow the seed by hand with the back bent, taking care to spread it as evenly as possible, and if you doubt your own skill in this direction, divide each portion of seed into two parts and go over the ground twice. The seed must now be covered to a depth not exceeding a quarter of an inch, and the most simple means of doing this is lightly to rake the surface in two directions, taking care not to bury it too deeply. The ground should then be rolled and cross-rolled with a light roller.

The young grass should appear above the ground in five to ten days if autumn sown, and fourteen to twenty-one days if spring sown. When it is about 1in. high, roll it with a light roller, a wooden one preferred, and a few days later cut it with a sharp, free-acting machine set rather high, or if a skilled man is available, it is better to make the first cutting with a sharp scythe. In any case do not make the fatal mistake of letting it grow 3ins. or 4ins. long before mowing, otherwise it may send out stiff bents and grow long and thin instead of tillering out and covering the ground, and so cause no end of trouble. From the time of the first cutting the lawn should not be rested from the mowing machine so long as the grass is growing, and a well kept lawn should be as closely shaven and as bright and green on Christmas Day as it is in June.

The choice of the quality of the seed should be governed by two factors, the type of turf required and the nature of the soil upon which it is to be grown. If the soil is of a heavy, sticky nature and there is no intention to alter its mechanical condition by the incorporation of sand, fine breeze or charcoal, use a mixture containing rye grass. Such mixtures germinate freely, grow quickly, and more or less hide any coarse grass that the soil may contain. Mixtures composed wholly of the finest grasses without rye grass are better suited to light, well drained soil, but they are more difficult to grow, because they are slow both in germination and growth, and coarse natural grasses show up like weeds in contrast with the fine velvety turf.

THE GREEK WINDFLOWER (ANEMONE BLANDA)

FROM the mountains of Greece comes this lovely species, which is about the first to open its charming flowers, and this before winter has left us.

It grows about 6ins. high and has flowers which measure 2ins. across, those of the type being of a beautiful deep blue, and there are charming shades among the varieties of pale blue, pink, deep rose and pure white, all of which are highly desirable for adding welcome colour to the garden in the early days of the year.

Although this species bears a great resemblance to the Apennine anemone, it is quite distinct from that plant, the former having a round tuberous root, whereas the latter has a creeping rhizomatous root and flowers several weeks later.

A very distinct variety of the Greek windflower and a very lovely one is A. blanda var. scythinica from north Kurdistan, which has pale blue and white flowers, the inside of the petals being pure white and the outside pale blue.

A warm sheltered border, the soil of which is a light rich loam, warm raised positions on the rock garden, and sunny slopes offer the surest means of success with this early flower.

With me it increases freely by means of self-sown seedlings in a long narrow border which faces south and south-west, and which is protected by a 6ft. wall. Naturalised in the grass, it survives, but does not increase to any appreciable extent.

E. MARKHAM.

THE BEAUTIFUL BLUE FLOWERS OF ANEMONE BLANDA EXPAND IN EARLY SPRING.

LILIUM AURATUM

BY A. GROVE.

HAPPILY there is no difficulty in telling the story of L. auratum, for, unlike L. candidum, Martagon and one or two more of the genus, the early history of the plant in this country is not covered by the dust of centuries. Much of its history, indeed, is to be found in the earlier numbers of THE GARDEN, for the founder of the paper has always placed lilies in the forefront of hardy plants, and given every encouragement to their cultivation wherever and whenever the opportunity has presented itself. As far as cultivation in this country is concerned, auratum is a modern lily, for though odd plants had reached Europe earlier in the century, it was unknown to gardeners generally before Messrs. James Veitch and Co. introduced it to public notice at the exhibition of the Horticultural Society in South Kensington, on July 2nd, 1862. Messrs, Veitch had received the bulbs from J. G. Veitch, who explored parts of Japan and China for his firm in 1860–61, and at about the same time Standish, the nurseryman, had also received bulbs from Robert Fortune. The lily naturally created a great stir in horticultural circles, and Dr. Lindley wrote a panegyric on it in the *Gardeners' Chronicle* at the time. Since then importation of the bulbs has been going on without a break except for the war years. When the treaty ports were opened in 1859, L. auratum, known to the Japanese as Yama-uri—the hill lily—grew in greater abundance on the lower slopes of Fusi-Yama than elsewhere. In a letter to THE GARDEN in 1878 (Vol. XIV, page 560), "E. H. W." wrote that "The soil that covers the crumbling igneous rocks to a varying depth consists of decomposed leaf soil, mixed largely with the detritus of this volcanic rock, that sparkles with particles of mica, and is excessively porous and friable. This lily grows on hill sides where there is perfect drainage, in a soil free from lime, in a climate that is both hotter and wetter than our own in summer, and in winter is dry and bright, with occasional sharp frosts of a few days' duration. Another point to be noticed is that this lily abounds at the edges of woods, where the dwarf bamboo, which in Japan takes the place of grass, effectually shields the stem and roots from the sun's rays, while the upper part of the stem with the broadest leaves rejoices in the sunshine." In an interesting account in THE GARDEN (October 7th, 1882, page 316), Maries, who collected plants in Japan for Messrs. Veitch in 1877, and to whom we owe Hamamelis mollis and Styrax Obassia, among other species, was a little more precise. "L. auratum," he wrote, "was growing on all the exposed grassy slopes near Fusi-Yama to an elevation of 4,000 feet, but always in tall, rough grass from 2 feet to 4 feet high. I seldom saw this lily in or under trees, but always in grass and among low bushes and always in peaty, leafy mould with pumice underneath, and not more than 3 inches of soil on the ground. . . . The mountain road to Fusi-Yama is a mass of auratum in June and July; every patch of open ground is covered with it. . . . Very often one sees a bulb of L. auratum sticking on the black earth by the mountain track. I have never seen above 25 to 30 flowers on a wild plant of L. auratum, and it seldom grows above 4 feet high, while in some places in England it often reaches more than three times that height."

In so far as the Japanese thought anything of the plant at all, they regarded it then as an edible root and nothing more. Probably because it is not so amenable to cultivation and is not increased so readily, L. auratum, as an edible bulb, has not the vogue of L. tigrinum—a common vegetable of the Japanese, and regularly cultivated as a field crop: but until the bulbs became more valuable for export than for food, they were sometimes cultivated in plots as a crop much as we cultivate onions. The Japanese have never prized the flowers, which conflict with their canons of beauty. To them the diminutive L. medeoloides—the wheel lily—represents the acme of refined elegance, and so they had no qualms about digging up the bulbs of L. auratum to supply the demand which sprang up for them in England and the United States soon after the port of Yokohama was opened to foreign trade. That was the beginning of the export trade in lily bulbs which grew and grew till it embraced all known Japanese species and varieties as well as some from China and Formosa, and has reached such huge proportions as threaten ultimately to leave Japan denuded of wild lilies. The extent of it may be gauged by a statement in the catalogue of the Yokohama Nursery Company for 1912, that over fifteen million bulbs were then annually exported: and though the trade fell to modest proportions during the war, and has since been seriously crippled by the catastrophe which overwhelmed Yokohama in the autumn of 1923, it will doubtless reach pre-war proportions in time.

Except for a minute proportion raised from offsets of cultivated, collected bulbs, every bulb of L. auratum shipped from Japan is a wild one, dug up by collectors whose business it is to find all the bulbs they can and, having found them, get them down to the merchants in Yokohama. It is many years since the last of the wild lilies was dug up on Fusi-Yama and in the neighbourhood of Yokohama, and then, to satisfy the ceaseless demand, collectors had to go further afield. Gradually, as locality after locality was stripped of bulbs, fresh ground had to be broken until now collectors have to seek for L. auratum in the northern part of the main island. Presumably the process will continue until the species ceases to exist as a wild plant, and then the Japanese must either give up the trade in these bulbs or raise the lily from seed.

Such varieties of L. auratum as virginale, cruentum, rubro-vittatum, Wittei and pictum are not hybrids, as is so often supposed, but natural forms propagated solely by offsets, and as that method is comparatively slow, the varieties in question are seldom available in quantities. Alive to the ease with which L. auratum and other Japanese lilies are raised from seed or by scale propagation, Western cultivators find it difficult to understand why an intelligent race like the Japanese perpetuate the system now in vogue, with its primitive methods and prodigal waste; but probably the low cost of collected bulbs and the fact that they can be turned into money in about a year, are the governing factors. It will hardly be believed that before the war (1913) the Yokohama market price of bulbs of L. auratum, 8ins. to 9ins. in circumference, averaged 1d. apiece.

When dug up by collectors, the bulbs are thrown into receptacles, of which the commonest is the ubiquitous American kerosene tin, loaded on to carts and trundled down through the long journey to the nursery gardens in and around Yokohama. Their condition on arrival at their destination depends in great measure on the weather, for if the bulbs are harvested in a wet autumn the mortality among them, even on the comparatively short journey to Yokohama, is severe. Once there, such as are not decayed, bruised or damaged beyond recall, are graded and then planted out in rich soil. As the stems appear and grow up, the ground is usually earthed up round the roots, just as potatoes are earthed up in this country, the process having for its object the rapid fattening of the bulbs for market, for they are sold by size: the larger the bulb the more floriferous will it be. In this connection we must remember that wild bulbs usually throw four to three flowers; and multi-flowered stems are comparatively rare. Writing to the *Gardeners' Chronicle* on February 10th, 1883, Mr. Bruère reported the receipt of a bulb 22ins. in circumference and 2lb. 3oz. in weight, from Messrs. Protheroe and Morris. One season is usually sufficient for the fattening process, and in the autumn of the year after they have been planted the bulbs are lifted and thrown into baskets, all offsets, of which each bulb usually produces several, being saved for cultivation in the same way as the bulbs. The latter are taken to the warehouse compound, where they are shorn of their roots, cleaned and graded, all obviously diseased or damaged bulbs being discarded. Incidentally, the latter are sought by the poor, who esteem them as a vegetable. Then the bulbs are enveloped in plastic clay till each resembles an apple dumpling, and as soon as the clay is all but dry they are packed in the familiar cases, the interstices between the bulbs filled in with dry, powdered clay and the cases shipped to their destination. Originally we were the best customers of the Japanese bulb merchants, but for many years past the bulk of the supply has

Digitized by Google

gone to the United States, where L. auratum, speciosum and longiflorum have always been appreciated.

The clay envelope had its origin in the mortality among the earlier consignments of bulbs, for at one time the losses were so serious as to render the export unremunerative. Bulbs of L. auratum are subject to a fungus disease (Rhizopus necans), which probably originates in the rich, heavily manured soil of the Japanese nursery gardens. In the days before clay was used to isolate the bulbs, the inclusion in a case of a single diseased bulb was sometimes sufficient to infect the contents of the case—anything from fifty to two hundred bulbs—and render them useless. Consignments were always sent at buyer's risk, and having paid for the shipments by bill of lading, the importer was left without remedy in the not infrequent event of a consignment arriving in an unsaleable condition. Various methods of packing were tried, such as sandy earth, charcoal and sawdust, but all failed, and a lack of co-operation between the parties involved did not help matters. Under the most favourable conditions, passage of the Red Sea, especially at the comparatively slow speeds prevailing in the 'seventies, must have been a severe trial to the bulbs.

(To be continued.)

THE ST. DABOEC'S HEATH

THERE are not many of the dwarfer ericaceous shrubs which can claim so many attractive attributes as the subject of this note and few are more worthy of being more widely grown. Its comparative scarcity in gardens may possibly to some extent be due to the popular misconception that this heath, being a "peat plant," demands a peaty soil, whereas it will thrive abundantly in any light or medium lime-free loam. It is not even very fidgety as regards moisture, for many of our best groups are growing in the light, gritty loam of banks so sloping that they have had to be propped-up by boulders or low retaining walls. Full exposure it enjoys, but it does not object to the partial shade of deciduous trees.

Daböecia polifolia is a native of some parts of western Europe, including Ireland. The type species has rose-purple, egg-shaped flowers, often ½in. long, on erect spikes, 6ins. or more in height, the little ovate leaves being a dark glossy green above with white undersides. There is a good form known as D. atropurpurea with flowers that tend to more of a mauvy-crimson hue, a remarkably fine variety, and then there is that curious affair, var. bicolor, or versicolor, which bears white, blush and purple-and-white blossoms all on the same plant. But the pick of the basket is unquestionably the variety alba, which was discovered in Connemara. This is not only more vigorous and more prolific than any of the foregoing, but the flowers are larger and ampler, lovely globes of snowdrop whiteness strung on upright racemes which often exceed 8ins. in length. The foliage of this form is also of a brighter, fresher green than that of the others. And this exquisite thing will begin to flower in May and continue in full beauty until the first frost of autumn. The only things that ever mar the chaste and delicate purity of the blooms are the bees, especially those little black fellows, which are demoralised enough, or intellectual enough —which you will—to pierce the corollas and so filch by illegitimate, back-door means, the nectar which they cannot otherwise reach. The result is that a sharp eye will notice that the white globes become pitted as if punctured by a rusty needle. (Who says that there are no rebels in Nature's well ordered realm who reck not to defeat her most cherished designs ?)

A PLEASING PICTURE IN THE WOODLAND WITH DABOECIA POLIFOLIA IN FOREGROUND.

When planting D. polifolia in our light loam we usually give the plants a fairly generous application of leaf-mould, working this about the roots, and the clumps are set deeply so that the soil comes well up to the foliage. They are not firmed in too hard and the heavier the soil the lighter should be the pressure and the more leafy material is required. Once planted this heath never gets any attention beyond an occasional clipping over in spring whenever this seems desirable by way of encouraging a compact and shapely growth. A distance of at least 24ins. should be allowed between each clump when grouping, but half of that will do when the plants are to form an edging. The height does not often exceed 2ft. This shrub is sometimes listed as Erica Daboecii, or as Menziesia polifolia. It has other aliases which are, happily, getting forgotten. A. T. J.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants ; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

PLANTING RETAINING WALLS AND BUTTRESSES

BY DR. R. LLOYD PRAEGER.

THIS IS ALWAYS A PROBLEM TO GARDENERS AND IN THIS ARTICLE DR. PRAEGER DESCRIBES THE BEST METHODS AND THE BEST PLANTS.

THE mania—for so many people will call it, and so it really is with some enthusiasts—for sticking plants everywhere is, to my mind, wholly commendable. If you do not do it, nature will, provided that the place in question is one where plants can grow at all. Furthermore, nature will choose those plants which she considers most suitable for the site, quite irrespective of their artistic qualities—the ubiquitous grasses, most successful of all races of plants; good serviceable things like daisies and brambles and couch-grass; or others with aeronautical tendencies like dandelions and groundsel and willowherb, whose flying seeds enable them to surmount every barrier and to perch in impossible places. Many of these cheerful vagrants are dear to every true lover of plants: also to the gardener—when they are in their proper place. But on the whole, the gardener prefers making his own selection of plants, even when he attempts the colonisation of unusual sites for horticultural effort: and he properly rejoices when he converts an old buttress or wall-top into a blaze of blossom.

There is often a considerable amount of art required to achieve success in such enterprises: nowhere is a careful reconnaissance—an intelligent study of the ground and the conditions—more desirable. If it is a retaining wall, what does it retain? Is it an earth slope which sends a plentiful supply of water into the wall? Or has the back of the wall got drainage in it, to remove percolating water? How does the wall face—north, south, east or west? A lot depends on this. And again, if you propose to use choice things, the question of climate comes in—notably as regards rainfall, temperature and sunshine. It can never be too much hammered into the enthusiastic beginner that Lancashire is not Devon, nor is Devon Essex, any more than clay is sand, or sand loam. So first of all study your site as you would the environs of a badly bunkered golf ball, especially as regards aspect and moisture; and to do this satisfactorily you must see, or at least envisage it in both summer and winter weather: according to your mature diagnosis you will plant it with anything from sempervivums to lady-ferns.

A DRY WALL WITH A WESTERN ASPECT AND MANY CHOICE INHABITANTS.

In planting a wall of any kind, there is one outstanding question, the answer to which will at once determine the nature of your work, and often the measure of your success. This is the obvious question—is the wall you wish to plant already in existence, or is it about to be built? If the latter, then all is well, and you may sail straight in. But if the former, the problem is more difficult, and a good deal of care must be taken. This is because of the difficulty in arranging properly the roots of plants in a wall already built. Especially if the situation or aspect is a dry one, it is most important that the roots of what we plant should be combed well back, that they may have access to the moister soil behind. This is easily done if we plant at the same time as we build, and this plan is very much to be preferred. But fate often decrees otherwise. There stands our wall already, and we have to make the best of it.

Success in this case—indeed, in either case—will much depend on the way in which the wall is built, and the nature and shape of the stones employed. These should be as long as possible in proportion to their height, as this diminishes the number and height of the vertical joints, which are a source of trouble, since it is by means of them that the earth is always trickling away. The upper surface of the blocks should be flat or even a little concave—not convex—so as to retain water which falls as rain, and pass it into the wall. All stones should, of course, be laid with a backward slope, to assist the same object as well as to ensure stability. The stones should be laid so as to break joint, the end of each stone being as far as possible over the middle of the one below.

The best spots for planting will be at the base of the vertical joints as thus arranged, in other words at the centre of the upper face of the stones. There they will have a good solid bed, and moisture will come to them from the joint overhead. In practice, of course, we shall have to put up with whatever building materials are available, and things will not work out so ideally: but the principle remains.

As to the plants to be used, these will depend entirely on what kind of wall we wish to plant. The subject may be anything from a little old buttress of a potting shed to a new 30ft. retaining wall which we wish to hide with a screen of trailers and shrubs. Let us consider the former case—an old mortar-built buttress. We can in the first place take a hint as to its suitability for planting from the weeds which it harbours. If devoid of vegetation it must be either very dry or very barren, and we shall proceed to scoop out holes as deep as possible, choosing spots at the base of the vertical joints. Make up a rich compost with plenty of leaf-mould (which holds moisture well); fill the bottom of the hole with it. Then insert your plant carefully—young, not old—working the roots well down, and then fill the hole in stages, tamping the stuff in as you go with a blunt stick. For dry conditions such as we have assumed above, autumn is the best time for planting, as a spring drought might well prove fatal if we delayed until that season. If our wall has a bank of damp earth behind it, or a northern aspect, we shall have less difficulty in getting the plants established, which is the main trouble when planting has to be done subsequent to building. When the two proceed simultaneously, there is no trouble. When a course of stones has been laid (sloping backwards as already specified), cover them with an inch or so of good compost. Lay the plants on this at the centre of selected stones (the distance apart varying according as the plants will ultimately be large or small),

Digitized by Google

see that the roots are well spread and kept well back, lay on a little more compost, and then the next layer of stones, breaking joint as already indicated.

As to the plants to be selected, we may first of all go back to our old dry buttress. For such a place no plants can beat the sempervivums, which can endure almost unlimited drought. They are so well known and so easy to plant as to need no comment. Their cousins and fellow-succulents the sedums prostrata, Polygonum Brunonis, PP. vacciniifolium, and Emodi, creeping thymes, Veronica incana. If cushions are desired, Saxifraga sancta and its invaluable hybrids apiculata, apiculata alba, and Elizabethæ never look better than on a wall—the sancta blood has a vigour about it not possessed by any other of the kabschias. Acantholimons will make fine clumps, notably A. glumaceum, as will many of the erodiums and Silene Schafta. Our old friends, Arabis albida, Alyssum saxatile,

A WALL GARDEN IN SPRING WITH A MASS OF BLOOM OF ALL SHADES AND TONES.

are to some extent impostors, in view of their fat leaves, for they do not really like very dry places, though they will endure them; there are very few of them that are happiest on a dry wall; most of them prefer rock-garden or dry-border conditions; a few (*e.g.*, S. pulchellum, and S. villosum) actually like a wet place. There are many plants more suitable than sedums for our dry buttress—pinks of sorts, onosmas, thrifts; silver-leaved things like artemisias and achilleas; subshrubs such as Pyrethrum densum, micromerias, santolinas, Cheiranthus alpinus, æthionemas; Anthyllis montana loves a dry spot, as does Nepeta Mussini and those two excellent hawkweeds, Hieracium gymnocephalum and H. villosum. Campanula Portenschlagiana, which has none of the characteristics which one associates with plants capable of resisting drought, does surprisingly well on a dry wall; and if you want a big bold thing, Othonnopsis cheirifolia will make a waterfall of glaucous leaves and golden flower-heads in impossibly waterless places. In view of the half-vertical position of the plants over each other, discretion must be exercised when planting, lest a bushy thing is so placed as to keep all the rain off some treasure immediately under it.

Following on these, there is a wide choice of plants which like fairly dry positions. If you want things that will drape the wall with curtains of foliage and flower, there are acænas of many sorts, the lovely aubrietias, Androsace lanuginosa, Dryas octopetala, Fragaria Daltoniana and F. lucida, Gypsophilla the rock roses and candytufts are invaluable when a bold effect is desired—they all ramp upon a wall. If we go to the other extreme and wish to try very choice things, we can break our hearts over Conandron ramondioides, Jankæa Heldreichii and the lewisias perhaps less often on a wall than in other situations.

Where moister conditions prevail, we can decorate with mossy saxifrages of many kinds, red, pink and white; the waldsteinias are vigorous, easy and attractive; and this is the place for the lovely ramondias and haberleas if we desire choice things.

Where the area to be planted is large—say a retaining wall 20ft. high—the use of many of the plants enumerated above will prove ineffectual, giving only a finicky effect. Something bolder is needed. The more robust rock plants—arabis, alyssum, aubrietia, waldsteinia, othonnopsis, etc., will help, but trailing or prostrate shrubs will often be needed. Of the former, vitis (ampelopsis) of many species is always available, producing a fine mass of colour in autumn to make up for its inconspicuous flowers. Ivies and honeysuckles can be used with good effect, and also cotoneasters—C. horizontalis is lovely in autumn, with its scarlet leaves and berries, and many of the prostrate kinds will be found useful. Wichuraiana and other vigorous rambling roses may be used with excellent effect. These are best planted on the top of the retaining wall and allowed to hang down, as in this way they can be manured

Digitized by Google

and otherwise attended to. The others mentioned should be planted *in* the wall, or at its base or top, according to their proclivities for climbing or hanging. There rises before my mind a vision of high retaining walls in the Canary Islands, supporting banana fields, and planted along the top with ivy-leaved pelargoniums, which hung down, a solid sheet of pink bloom a dozen feet deep. But our much-abused climate does not permit this kind of thing. Where you have to deal with a wall which is really damp and does not get much sun, ferns may be used to great advantage. They delight in such a situation, and there is such a variety of beautiful forms to choose from that a discussion of them would require a separate article.

SECATEURS AND OTHER GARDEN TOOLS

I TAKE a great interest in all garden tools, especially such as are used in pruning. For a long time I looked with suspicion upon secateurs of all kinds, thinking them to be very inferior to a pruning knife. However, experience proved that a good pair of secateurs beat a knife on several counts. One is that when on a ladder pruning wall trees one has a much longer reach with them than one has with a knife—if able to use one's left hand the space pruned without moving the ladder will be double that which can be covered with a knife. Again, once the action of secateurs has been mastered the work can be far more quickly done. This has been proved in nursery work over and over again. But—and it is a very important "but"—the secateurs must be good ones, handy to use, capable of making a clean cut, and not readily put out of order; also with blades which will take and keep a good edge for a reasonable time. I have tried endless patterns of this useful tool, but have found very few really good ones, lots of really bad ones, many indifferent. In one or two cases where a good pattern has been secured, a further supply was unobtainable. One excellent pair came from a Sheffield firm, but on trying to get another lot they were found quite different and very inferior. The fact is the English makers are quite out of the running in competition with other countries in the manufacture of secateurs. They will not take the trouble to find out what is the best form to adopt, and the steel they employ is not as good as that used by the best French makers. Perhaps a really good garden tool of any sort is wasted upon many amateur gardeners, because not one in ten takes any proper care of garden tools; their spades and hoes are perennially rusty, their knives and secateurs ditto, and probably, when required, a long hunt will ensue before they are unearthed from some hole or corner where they were put when last used. It would save a great amount of time, annoyance and hard work if the gardener would make up his or her mind to have a place for each and every garden tool in a dry building: point one. Point two: keep a piece of greasy waste or rag in the place where tools are stored, and after using spade, hoe, hedge shears, or other steel tools, wipe them dry, and then rub over with the greasy rag, before hanging them on nails or hooks on a dry wall. If this be done regularly the tools may be kept as bright as silver with very little trouble, and when required for use they will be in perfect condition at a moment's notice. Before winter sets in such tools as hoes, which will not be required for months, should have a coating of vaseline, which is a better protection than oil. I know that this is a counsel of perfection and not easy to keep up, but I assure my readers that it is well worth trying, even if one should at times fall somewhat below the high standard aimed at. Neglected, rusty tools must either be scoured with emery-cloth and oil—a nasty, grimy job—or have gradually to be cleaned by work; and all the time this is being done nearly twice the labour is being expended that would have been put into the work with a clean, bright tool. Not only so, but in the case of a rusty hoe the work will not be so satisfactory. This is a long digression from the subject in hand, but the point I want to bring home is this, it is useless to spend a lot of money on good tools if one does not keep them in order. One rusty spade is about as good as another rusty one, but an indifferent bright spade is better than a good rusty one, while the best pattern if kept bright will easily beat all others!

To return to our secateurs. The careless gardener would do well to stick to cheap patterns, for if he should buy the best they will soon be ruined, and two or three pairs may be had for the price of a high-class pair. On the other hand, to the person who loves his tools and delights in their smooth and efficient working, I would say, have nothing short of the *best*, and take every possible care of them. They will outlast any of the cheaper articles and will always be a pleasure to use. Not enough is made of the pleasure of work: if one be in fair health and does not try to do too much at a time, garden work should be a pleasure in itself, irrespective of the results obtained.

I can safely say that of all the many secateurs I have tried none has pleased me so much as those lately advertised in THE GARDEN by Mr. C. A. Jardine. They are called the "Guienne"; they are made in France by French workmen and are sold literally by the million at home and abroad. They are by no means cheap, in fact, some would call them very dear, but when one finds them cutting green wood like a pat of butter, one forgets the cost in the delight of work well and pleasantly done. J. DUNCAN PEARSON.

EARLY SPRING FLOWERS AT VINCENT SQUARE

WITH the advent of the second Show of the year at the Royal Horticultural Society's Hall, Vincent Square, on January 27th last, the early spring flowers presented themselves, bringing with them a dash of colour and fragrance which raises one's hopes for what is to follow in the later seasons of the year. It was, indeed, a gay and festive scene which met the eye on entering the hall. Spring flowers were there in plenty, and we realised perhaps for the first time that we were really leaving winter, with its dull gloom and fog, behind once again.

Perhaps the most outstanding exhibit, and one which commanded attention, was that of a magnificent collection of forced bulbs comprising hyacinths, tulips, freesias and daffodils, arranged by Messrs. Sutton and Sons of Reading with their customary skill and taste. The group was an extensive one, and the effect in the mass was striking, while the quality of the individual blooms was excellent. Hyacinths, perhaps, were the prominent feature, and of these the graceful cynthellas were predominant in shades of blue, pinks, whites and yellows. Roman hyacinths were conspicuous by their absence. It may be said in passing that apparently the stock of this class is low and, at present, growers are doing their utmost to increase it. For general decoration the multifloral hyacinths will be found to be of great value, as their large-flowered spikes, carrying many flowers, look exceedingly well in vases; and then, again, their early-flowering quality gives to them an especial recommendation. In tulips there was a wide selection offered in all shades. Among the many varieties which were on show were a few of note, such as William Copeland of a delicate lilac shade, Fireball, Proserpine, Vermilion Brilliant, La Reine, Montresor, Duc Van Thol and many others too numerous to mention. The numbers of these forms bring home to one the enormous amount of time and labour which has been expended on this flower, and it is indeed gratifying to witness the success which has attended the efforts of the hybridist and the raiser of tulips. It is a flower which will never lose its place in our hearts, partly owing to its bright and varied colours and also partly to its season of flowering. Freesia Excelsior was also in good condition, along with Crocus La Majestueuse, while a few well grown plants of Iris reticulata having a dark tone were interspersed throughout the bulbs along with palms, asparagus and ferns.

One always associates early spring with primroses, and on Tuesday last one was not disappointed. Messrs. Carter and Co. provided a really fine show of varieties of this valuable plant for this time of the year. Their variety of P. malacoides Princess Mary predominated, and of the several varieties of this species which exist Princess Mary is distinctly one of the best. That this has been recognised is clearly evidenced by the fact that it received an award of merit in 1922 and is still to the fore. In this variety the flower-stems are much taller and bear more numerous whorls of substantial flowers of rosy mauve colour. It has a better constitution than most varieties of this species. Numerous forms of P. stellata lent a distinct and subtle colour to the stand. The colours of such varieties as Carter's Crimson King, Holborn Rose, Carter's Salmon, Carter's Fairy Queen combined with a graceful habit and elegance were much appreciated and admired.

Digitized by Google

For greenhouse decoration at this season of the year P. stellata and its numerous varieties are really invaluable, few flowers being able to provide such a wealth of colour and bloom as this useful species.

The exhibits of the earliest blooming rock plants showed what brilliance they can display, especially when given a little protection from the rough weather. In the open, although invincibly hardy, the earlier ones are too often beaten down, muddied and discouraged by the storms of the new year, but in a cold greenhouse they give a wealth of subtle colour and scent that is being more and more appreciated.

Messrs. Waterer made a picture with Iris Sind-pers and Pulmonaria angustifolia rubra, pale aquamarine and old rose, against a dark background of dwarf conifers. Iris Sind-pers retains the wavy petals and most of the strange colouring of its parent I. persica, but is larger and more vigorous, and it seems as though it may take the place that persica has held so long, though so precariously, in the garden. In another part of the exhibit the creamy white of Narcissus triandrus albus made an interesting combination with the dark red, waxy berries of Pachysandra terminalis. A number of iris species were shown, the two yellow Junos, bucharica and orchioides, beside a mass of dark violet reticulata and a well flowered clump of Iris stylosa.

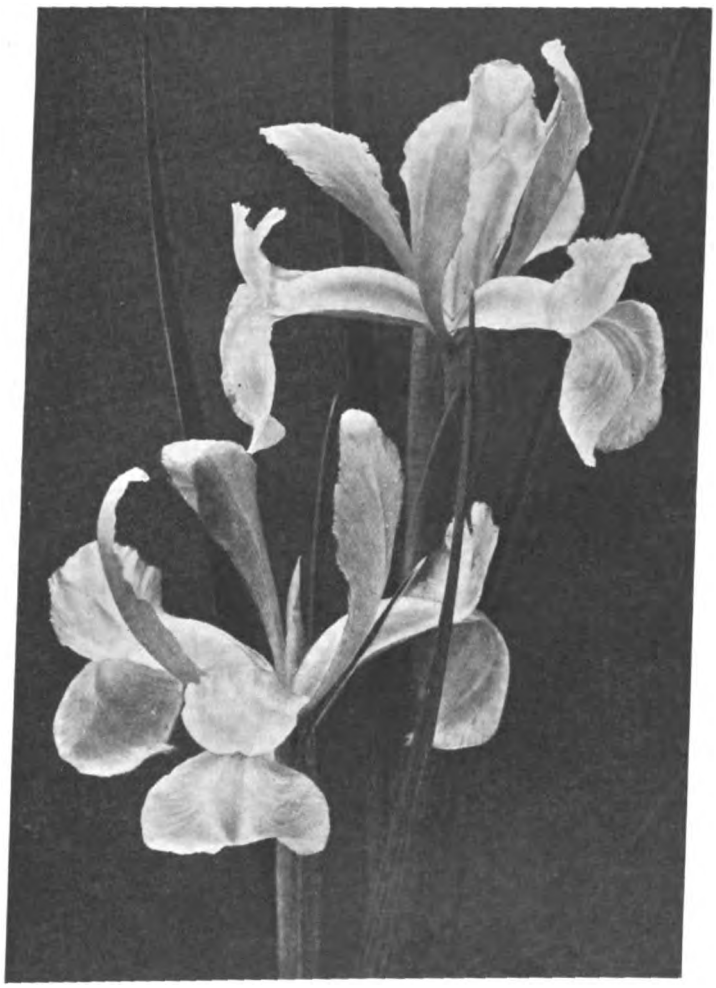
Messrs. Barr's collection was less conspicuous, but especially interesting in detail. They showed the new varieties of Crocus chrysanthus raised by Mr. Bowles, Snow Bunting, pallidus and a small pale type, all exquisitely formed globular flowers boldly feathered in blackish purple on a creamy or yellow ground. Crocus Adami was another newcomer to the garden, the bluest and one of the rarest of crocuses, that seems rather reluctant to open its long violet-blue buds. Crocus corsicus, rather like a minute Imperati, should find a place in the miniature rock garden. Another good plant was Iris stylosa var. speciosa, darker and slightly larger than the type, with a distinct peacock's eye on the fall.

Good specimens of Galanthus Elwesii showed their superiority to the common snowdrop in their large massive flowers, heavily marked with green, swaying on tall stems. This species seems to have become scarce since the war, and it is good to see it back again. A pale yellow hybrid of Helleborus orientalis, though rather greenish in tone, combined well with the deep purples and gave promise of the really pure sulphur yellow that would be a great acquisition to the group.

The exhibit of Messrs. Cutbush brought out the full value of some of the early-flowering shrubs. Cydonia superba var. Warleyi, in dull orange red, was grouped with a fine woody specimen of Hamamelis arborea, covered with its brownish yellow flowers, and the frosty white and dark green of Andromeda polifolia. They are three choice shrubs, and hamamelis has the special attraction of a curious, woody scent, faintly reminiscent of patchouli. A clump of the fine red form Brilliant of Tulipa Kaufmanniana was also shown, but its colour will be fuller in the open next month.

Messrs. Cheal showed a large group of the vigorous and beautiful Crocus Sieberi, with C. biflorus pusilla and Eranthis cilica, neater and more distinguished than the common winter aconite, with large pale yellow flowers and fine cut foliage.

An exhibit which excited much enthusiasm among those who are artistically and botanically inclined was that arranged by Miss Willmott. It consisted of a very fine collection of crocus drawings by Mr. Champion Jones. They were well executed, combining grace of line and botanical accuracy which is rarely found in drawings of this class. The exhibit deservedly gained a silver medal. A rapid survey of the drawings brought the realisation of the many wild species of this genus which can be had in flower in winter even around London.



THE BLOOMS OF IRIS WEDGEWOOD. A NEW EARLY FLOWERING VARIETY.

By the fine exhibit of rhododendrons of Messrs. Gill and Sons of Falmouth the mildness of the Cornish climate was again brought home to one. The blooms were in good condition, hybrids of L. Nobleanum, specimens of Cornubia with deep blood red flowers. This latter is a hybrid of R. Thomsoni, and it maintains all the good points of this species. White trusses of R. argenteum were present, but were showing the effects of their long rail journey. It is pleasing and stimulating to catch a glimpse of trusses of rhododendron bloom at this time. It is a genus which as the years go on will probably come more and more to the forefront of the horticultural world, and the pioneer raisers of the family deserve every credit for their untiring efforts to prove its worth in our gardens.

Among the other exhibitors were the following:

Carnations.—Messrs. Allwood Brothers, C. Engelmann and Stuart Low and Co.

Cyclamen.—Messrs. Stuart Low and Co., Caledonian Strain Floriculturists.

Fruit.—Messrs. J. C. Allgrove, Messrs. Waterers, and Westmacott Co., Limited.

Greenhouse Plants.—Messrs. L. R. Russell, Limited.

Orchids.—Messrs. Stuart Low and Co.

Rhododendrons and Hippeastrums.—Messrs. R. Gill.

Roses.—Mr. Elisha J. Hicks.

St. Brigid Anemones.—Messrs. Reamsbottom and Co.

Shrubs.—Orpington Nurseries Company.

Shrubs and Alpines.—Messrs. Bakers, J. Cheal, Carter Page and Co., William Cutbush, G. Reuthe, Skelton and Kirby, and F. K. Wood.

Artists.—Edith A. Andrews, Maud Angell, N. Blacklock, Agnes Foreman, Winifred Walker, Ellen Warrington and Mrs. Russell Walker.

Coloured Photography.—Messrs. T. B. Latchmore and Sons.

Garden Architects.—Mr. Percy S. Cane and Miss Evelyn N. Cowell.

Garden Books.—"Country Life," Limited.

Garden Contractors.—Johnstone Garden Contractor Company.

Horticultural Sundries, Tools, etc.—Alice L. Barker (bowls), Ashstead Pottery, Limited (china bowls), Chase Continuous Cloche Company (adaptable plant protectors), Carter (labels and insecticides), A. Everitt (gardening gloves), Thomas Gunn, Limited (tools), House and Garden Sundries Company, Limited (rubbish destructor and sundries), J. Jardine (Médoc and Guienne secateurs), London Garden Florists (bowls), Radium Fertiliser Company (fertilisers), Mrs. E. Torkington (Wizard plant labels), "Socleano" Limited (labels), Fraser, Treleaven and Wilkinson, Limited (flower-pots), Charles H. Pugh, Limited ("Atco" motor mowers), Miss Moutray Read (aprons), Walkers (fruit tree protectors), H. J. G. Wood (Willmott plant supports), William Wood (sundries and tools) and Ymagynate Pottery (china bowls, etc.).

NEW & RARE PLANTS.

IRIS WEDGEWOOD.—This hybrid is an early-flowering variety for market purposes. It was evident from the blooms shown that the plants are of good habit and growth. The flowering-stems varied in height from 2ft. to 2½ft., and carried a single large flower. The flowers were of varying shades of blue, blue-purple in parts fading to more delicate tints, stained with yellow down the centre of the falls. In this way, probably, the blooms lacked vividness. Nevertheless, it is a variety with undoubted merits as a decorative plant. It was obtained by crossing Iris tingitana with an early-flowering form of Iris xiphium, and while the hybrid has retained the robust and hardy constitution of its Spanish parent, it has not lost the early-flowering character of the other. It will prove a useful variety for obtaining cut flowers at this season. Award of merit. Shown by Messrs. Lowe and Shawyer, Uxbridge.

Digitized by Google

CROCUS CHRYSANTHUS BUMBLE BEE.—Unlike so many other forms which have been raised by Mr. E. A. Bowles, and which bear the varietal name of a bird, this one bears the name of an insect, and it is indeed aptly described. It varies from the type in being a yellow form with a greyish throat and tube. The interior is of a satiny yellow, while the outer segments are suffused with purple or brown. It is a dainty form and when half open the inner segments resemble the golden bands found on the body of a large bumble bee. Award of merit. Shown by Mr. E. A. Bowles, Myddleton House, Waltham Cross.

CARNATION HERCULES.—Well shaped blooms of a scarlet colour and of good substance borne on tall, stiff and wiry stems were the characteristic features of this variety. The calyx has no tendency to burst. Unfortunately, there is little fragrance in the flower. It is a variety which should prove useful from a decorative point of view, especially for the table, as its colour is one which will give good effects against a white background. Award of merit. Shown by Mr. George Carpenter, Byfleet.

ORCHIDS.

CYPRIPEDIUM MRS. WILLIAM PICKUP (Alcibiades × Thisbe).—A vigorous plant bearing a large flower of very pretty qualities. The dorsal sepal flushed with purplish rose colour, stained on the basal area with brown, and having the upper part pure white, the margin being effectively crisped; lateral petals and labellum well developed, honey yellow in colour, tinged with reddish brown. Shown by Dr. F. Craven Moore, Victoria Park, Manchester. First-class certificate.

AWARDS OF MERIT.

ODONTONIA NESTA (Odontonia Gladys × Odontoglossum St. George).—A promising seedling with an erect spike of three medium-sized flowers, in formation showing the miltonia habit, derived through M. Blueana, a component of the former parent. Segments blotched with crimson-rose, the broadly developed labellum having some brownish markings on the basal area. Shown by Messrs. Charlesworth and Co., Haywards Heath.

ODONTOGLOSSUM CERAMIC (Watsonii × eximium).—This handsome hybrid carried a spike of fourteen large flowers, the broadly displayed sepals tinged with yellow, the petals whitish, and all the segments effectively marked with chocolate red blotching. Shown by Messrs. J. and A. McBean, Cooksbridge, Sussex.

BRASSO-CATTLEYA BIANCA VAR. AURAMINE (B.-C. The Baron × C. Mendelii).—A useful addition to the Brassavola section. The two flowers borne by this plant were unusually large, white, except for a slight tinge of pink, the expansive labellum deeply fringed at the margin and with an orange-yellow throat. Shown by Messrs. J. and A. McBean, Cooksbridge, Sussex.

SANDER MEDAL.—In commemoration of the valuable services rendered to horticulture by the late Mr. H. F. C. Sander, the firm of Messrs. Sanders, St. Albans, presented to the Royal Horticultural Society the Sander Medal, to be awarded annually for the best greenhouse novelty of the year. For the year 1924 it has been awarded to Mr. G. F. Moore, Chardwar, Bourton-on-the-Water, Gloucestershire, for raising Cypripedium Doris Stanton, exhibited on December 2nd, when it received a first-class certificate.

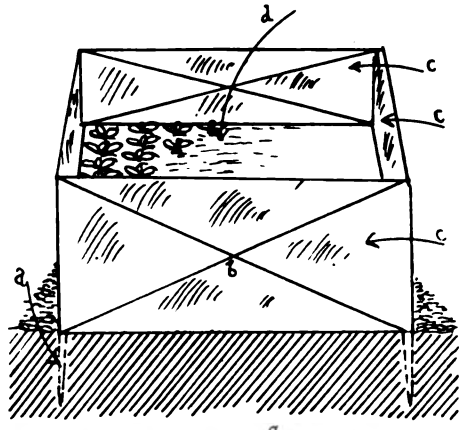
SIMPLE GARDENING

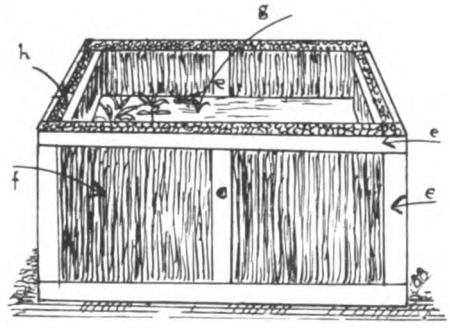
FORCING STRAWBERRIES.

THE first ripe strawberry is always much appreciated, especially if we grow it in our own greenhouse. Of course, the only way to ensure success with the plants is to pot good runners in due time, as soon as runners are available after the fruit is gathered in the open beds. Such potted plants have been wintered outside and are now available for forcing. I refer to gentle forcing, as plants subjected to heat earlier in the season are now bearing fruits which will soon be red. We will presume that only fifty plants in pots are to be forced; these should be subjected to the artificial heat of a greenhouse in various batches to prolong the supply of ripe berries, and not all at one time. A nice strong plant, possessing a plump crown, will bear at least half a dozen large, and as many medium, sized berries. First, see that the drainage is clear and that all weeds and side shoots are removed before the pots are placed on the shelf in the greenhouse. From the time that the plants are placed under glass to the date of ripening berries, the soil must never be allowed to become dry. Directly the young berries are formed, weak liquid manure should be applied at every watering, but clear water only after colour shows. When in flower tap the trusses daily with the fingers. On every fine day syringe the foliage to prevent the spread of red spider. Bring in the succession batches every fortnight.

SIMPLE SHELTERS.

In a few week's time it will be necessary to transfer many plants from greenhouses and warm frames to cooler quarters. I am referring, mainly, to summer bedding-out plants, to spring-rooted cuttings, seedlings of half-hardy annuals, young onions, leek and cauliflower plants and to the various batches of chrysanthemum plants which would soon spoil if retained much longer in a greenhouse temperature. The difference in temperature between that of the greenhouse and the open air is too great for the well being of young plants at the season of the year referred to—mid-February to mid-April. Amateur cultivators do not, as a rule, possess any spare frames with





glazed lights to devote to the kinds of plants above referred to and they will find the simple plant shelters, as shown in the sketches, very useful for the purpose. In one of the largest gardens in this country a huge straw frame was used for many years with great success. Every spring it contained many hundreds of plants and, during the summertime it provided just the right shelter needed by the roots of azaleas. It is made of dressed straw, firmly packed in a framework. A more temporary plant shelter is one of canvas stretched to stakes as shown at *a*; *b*, cross laths; *c*, *c*, *c*, canvas; *d*, plants. Letters *e*, *e*, *e*, *e*, show framework; *f*, straw; *g*, plants; *h*, shows the ends of the closely packed straw cut off level, the straw sides being 4ins. thick. Mats or canvas would form a suitable covering at night.

CALCEOLARIAS, CINERARIAS, PRIMULAS AND CYCLAMEN.

The three last-named kinds of plants are now flowering profusely in our greenhouses and conservatories and the first-named will augment the display in the course of a few weeks. Rotted manure is often included in the potting composts and, in some manures, especially that taken from pastures where cattle graze, white grubs are found; some plants collapse suddenly just when they are approaching the flowering stage; this happens to calceolarias, but mostly to cinerarias and primulas. Many grubs breed in the compost, from a previous state, after the potting has been carried out, and eat the roots; one or more will enter the stem of the plant, eating its way upwards and directly the grub reaches the point just above soil level the plant droops and dies suddenly. These grubs are not always confined to cow manure, but may be found in various soils used for potting purposes. If a fine wire or a needle be driven through the stem of the plant in several places near its collar, the moment any drooping of leaves is noticed, when such drooping, distressed appearance is not caused by over, or under watering, the grubs may be killed in the stems. I have frequently killed them so and not damaged the plant by the piercing of the stem. The roots of these plants are soon injured by over-feeding, and amateurs are sometimes guilty of over-feeding through eagerness in attempting to beat records as regards big flowers. Always apply stimulants in a very weak state and not more frequently than twice a week. Calceolarias, from the present date to May, thrive well on a cool base. Old, well washed ashes or gravel will answer the purpose; spread them on slates where there are wood stages.

GEORGE GARNER.

CORRESPONDENCE

RHODOSTACHYS ANDINA.

SIR,—It may interest your correspondent, Mr. McMullen, that I have in a south garden here (East Cornwall) three plants which exactly tally with his photograph and description of his Rhodostachys andina. Mine have two botanical names, Pourretia or Dyckia frigida. They are in flower now (January 20) as they usually are at this time of year. They have been here for about twelve years, but I do not know where they came from, but think that they must be closely allied to the plant that he mentions. I have also in the same garden on a south wall Lassiandra macrantha and Luculia gratissima, the latter just coming into flower.—MOUNT EDGCUMBE.

SIR,—I was greatly interested in the excellen picture of Rhodostachys Andina which figured in your issue of January 17th. It is a very interesting class of plant and one that always arrests attention, especially when in flower. It is quite a small genus, six or seven species being described. They are natives of Chili, Columbia and Guiana. We have two large plants growing in the rockery in these gardens. They were given to Mrs. R. C. Bainbridge by the late Mr. Wyndham Fitzherbert, who was an interesting contributor to THE GARDEN. These plants have been in their present position about ten years and for the first time one of these plants produced two flowers last September and remained in bloom for a considerable period. The description given by Mr. McMullen of his plant R. Andina is precisely the same as those growing here. I sent a plant to the Curator of Kew, he named R. Pitcainiæfolia. I also wrote to Mr. W. R. Dykes, Secretary of the Royal Horticultural Society about it. His reply was that it rarely flowered in the open air in this country, although it had been reported to have flowered in the South of Cornwall. But at Tresco Abbey, Isle of Scilly, it frequently blossomed. The old inflorescences are still intact on the plant, but the leaf spikes surrounding it have resumed their natural green.—F. W. RICH, *The Gardens, Ffordleigh, Plympton.*

VEGETABLE SEEDS FOR A SMALL SUBURBAN GARDEN.

SIR,—Mr. J. Comber is quite right (page 38). I do not mind, in the least, honest criticism, and am always willing to reply to it. I only write from practical experience, an experience extending over forty years. Obviously, it is not possible to enter into all detail treatment is such short notes as those in "Simple Gardening"; detail treatment is embodied in articles which appear in THE GARDEN from time to time. I try to give a lead or guide to inexperienced cultivators, and intelligent readers will use their discretion as Mr. J. Comber does. Very few owners of small gardens will grow all the kinds named in the table referred to; each one will make a selection, growing those that are liked best. In the table one kind is named, but it does not mean that only one variety is to be grown; for example, several varieties of celery may be grown: this means as many packets, and the aggregate should not exceed half an ounce. The same applies in the case of broccoli and cauliflowers, several varieties of each to ensure as long a supply as possible. It does not follow that all seedlings raised are planted finally. Pea and bean seeds are often sown too thickly these resultant plants podding where raised; for this reason I say 1 pint of early pea seeds will sow a row 50ft. long and 1 pint of main-crop a row 60ft. long, as the latter require more space—this is a guide. But it is news to me that globe artichoke plants from seed will attain to a size sufficient to cover a space 6ft. wide in one season My plants measure about 2ft. in width after one season's growth. Seeds of these often fail to germinate sown outside, as amateurs generally must sow them, and from the 1 oz. of seed probably there would not be a surplus of plants available for the owner. I congratulate Mr. J. Comber on the excellency of his soil. One wishes to grow a score of plants of a certain variety of cauliflower, and one must buy a tiny packet of seeds of that variety, and in it, most likely, there are 400 seeds. Well, one cannot eat half a sheep without killing a whole one.—GEORGE GARNER.

BERBERIS NEPALENSIS.

SIR,—The illustration below of Berberis nepalensis may be of interest to many readers of THE GARDEN. The plant has formed a beautiful bush 10ft. in height and about 14ft. across, and when it was at its best was laden with 180 flower spikes. These were, on the average, about 9ins. long. The plant is now twenty-five years old and has kept its bushy habit remarkably well. It is growing in the garden of Mr. J. Ellet Lake, Glencoe, St. Leonard's, Exeter. It would be interesting to discover if any readers of THE GARDEN have seen a bush approaching this size.—PETER VEITCH.

A VERY STRIKING BUSH OF BERBERIS NEPALENSIS LADEN WITH FLOWERS.

COLOURS IN HYDRANGEAS.

SIR,—When I wrote to you recently (December 13th, 1924, page 837), regarding colours in hydrangeas, I relied entirely upon my memory, but upon referring to the work done by Professor C. H. Connors, Assistant Horticulturist of the New Jersey Agricultural Experiment Station, I find that the simple statement I made regarding the use of lime must be qualified so that your readers may not use too heavy an application of the wrong form. Too much lime, if in a caustic form, causes chlorosis, due to the precipitation of the iron salts in the soil solution, these iron salts being necessary to the formation of chlorophyll. Plants will become yellow and stunted in growth, also root injury results when heavy applications are made.

By taking a lesson from the pink hydrangeas grown in England in chalk soils, experimental work was conducted which demonstrated that the form of lime to use was important. Ground limestone, unburnt limestone, can be used in large quantities with safety—10,000 pounds to the acre have been used without any perceptible deleterious effects—but a slight excess in the soil of hydrated or slacked lime causes chlorosis. Caustic forms of lime may be used provided only enough is used almost, but not quite, to cause an alkaline reaction.—PARKER T. BARNES, *Harrisburg, Penn, U.S.A.*

ROSE TRIER.

SIR,—May I briefly supplement the article on Rose Trier appearing in your issue of January 10th, as "Claremont" seems to be at fault with regard to its origin and (judging by his remarks) the source and pronunciation of its name? As to the latter, I remember that many years ago, when I was discussing this particular rose with Mr. A. Paul in his old nurseries at Waltham Cross, he corrected me and gave me some account of its story. R. Trier is a hybrid musk, and was raised by P. Lambert and sent out three or four years after his masterpiece, Frau Karl Druschki. Although it is true that, as "Claremont" states, "this rose is always endeavouring to bloom," its *rightful* (his epithet) name has no connection with the English word try. P. Lambert christened his rose after the ancient town of Trères, or Trier (to give it its Prussianised form). I grew the rose for many years, but it never reached with me more than 5ft. to 6ft. in height. As is the case with several other so-called pillar roses, I fancy R. Trier is more beautiful and effective if grown as a large bush and allowed to develop at will, any necessary supports being given as required.—A. N., *Surrey.*

GARDENING OF THE MONTH

FLOWER GARDEN.

DAHLIAS.—Prepare site by bastard trenching the ground.

HERBACEOUS BORDERS.—If weather suitable, finish planting and renovation work. Replant delphiniums if overgrown. Top-dress old plants of Gypsophila paniculata with a compost of equal parts of loam, old mortar rubble and sand.

RANUNCULUS.—Plant at end of the month. Place claws downwards, cover with sand and 1in. of soil.

ROSES.—Hoe the beds. Give a dressing of manure to those beds which were not fed in the autumn. At the end of the month take down climbing roses and cut out dead and worn-out wood. Re-nail securely. Finish planting if ground is in good condition.

FRAMES.—Pinch out centre of violas and calceolarias. Remove decaying matter and stir the soil.

HARDY FRUIT.

APRICOTS.—Prune, train and top-dress, using compost of four parts loam, one part lime rubble and sand.

BUSH FRUIT.—Plant or transplant currants and gooseberries. Fork in between established plantations and mulch with farmyard manure. Take more cuttings if required. Net the bushes, if possible, or spray with quassia extract to keep off the birds. Make firm all autumn-struck cuttings.

CHERRIES.—Prune Morello cherries if not already done. Top-dress the borders.

FIGS.—Remove the protection if weather favourable. Prune and thin out superfluous branches.

GREASEBANDS.—Examine and replenish if necessary.

PLANTING.—Finish soon. Tread firmly trees planted during the autumn.

PRUNING.—Complete soon. Slightly prune autumn-planted trees which have rooted.

RASPBERRIES.—Cut back newly planted and autumn-fruiting canes to within 6ins. of the ground.

SPRAYING.—Continue using caustic alkali.

NUTS.—Spur prune and shorten the leaders. Keep the centre of the bushes open.

VEGETABLES.

HERBS.—Lift perennial kinds and transplant in fresh ground.

JERUSALEM ARTICHOKES.—Plant out in well prepared ground.

LETTUCE.—Plant out cabbage lettuce on a hot-bed.

PARSNIPS.—Sow on well prepared ground which was manured the previous season.

POTATOES.—Plant out sprouted tubers in a warm situation. Rub off weak shoots. Set up in boxes another batch for sprouting. Use early immune varieties.

RHUBARB.—Cover some of the crowns with pots or boxes. Place stable litter on top and completely cover with leaves. Divide and replant overgrown crowns in well manured ground. Plant 3ft. apart.

SHALLOTS.—Plant out as soon as ground is dry enough.

SOWINGS.—In the open ground on a warm border sow broad beans, onions, spinach, early round-seeded peas, early varieties of turnips and carrots. In frames in boxes sow early cauliflower, summer cabbage, leeks and Brussels sprouts. On a hot-bed sow carrots, turnips and onions. Scatter lime over the soil in each case before sowing.

SHRUBS AND TREES.

PRUNING.—At end of month cut back straggling branches of arbutus, clerodendron, euonymus, myrica and rhus. Cut back to the old wood at the end of February buddleia, Hydrangea paniculata, sambucus, tamarisk, Spiræa japonica and S. Aitchisonii. Trim slightly, to produce compact bushes, caryopteris, choisya, cotoneaster, hypericum, olearia, rhododendron, and stephanandra.

FLOWERS UNDER GLASS.

ACHIMENES.—Place rhizomes in boxes of leaf-soil and sand. When growths 2ins. long, pot up.

ANNUALS.—Feed those in pots. Sow in pans asters, larkspur, East Lothian stocks, verbena, salpiglossis, nicotiana, lavatera, Phlox Drummondi, Statice Suworowi, etc., and make further sowings of antirrhinums, sweet peas, alyssum and pentstemons. Prick off into boxes soon.

BOUVARDIA.—Bring out those resting. Shake out and pot up. Strike cuttings in mild bottom heat, using a peaty compost.

BEGONIAS.—Prick off into pans and return to propagating case. Later prick off again and place on a shelf in a temperature of 60°.

BULBS.—Keep temperature moderate, do not force too hard. Bring in potted gladioli from the plunge at the end of the month. Feed freesias after flowering and then dry off the bulbs.

CALCEOLARIAS.—Dust with tobacco powder to keep down aphis. Keep conditions cool. Start into growth those in store during the winter. Shift herbaceous calceolarias into larger pots.

CARNATIONS.—Take more cuttings, bottom heat essential for striking. Pot, in equal parts of loam and leaf-soil and little sand, immediately cuttings struck. Wash off sand attached to roots when removing from propagating case. Re-pot at end of month, using a compost of three parts loam, one part flaky leaf-soil, and little burnt ash and lime rubble. Pot border carnations.

CHRYSANTHEMUMS.—Take more cuttings. Strike cuttings from border varieties now in frames. Pot on young plants, using more loam at each shift. Keep temperature 50°–55°.

CINERARIAS.—Feed and fumigate. Stake the stellata section.

CYCLAMEN.—Keep fairly dry and temperature 50°–55°. Pot on when ready.

DAHLIAS.—Bring out from store. Set in boxes in a warm house. Sprinkle soil among tubers. Propagate by cuttings from the ensuing growths. Take cuttings with a small heel and place in a propagating case with bottom heat. Do not cover case with glass. Sow seed in pans and later transfer to small pots.

DIANTHUS.—Sow seed in pans, place in gentle heat.

FERNS.—Divide and repot. Slightly loosen the ball of soil.

FUCHSIAS.—Take out from resting place old plants, pot up and syringe. Take cuttings from the young growths, give them a little bottom heat. Pot on young plants in 6in. pots. Do not pinch.

GLOXINIA AND STREPTOCARPUS.—Sow seed, place in bottom heat of 65°–70°. Prick off when ready and guard against damp. Handle carefully as leaves are very brittle.

HIPPEASTRUMS.—Re-pot or top-dress. Pot up offsets and plunge in bottom heat of 60°. Water carefully.

HYDRANGEAS.—Pot on young plants. Start H. paniculata into growth. Prune hard back and introduce into heat.

LOBELIA CARDINALIS.—Take out of storage, divide, pot in small pots. Place in a heated pit and later remove to a cold frame.

PETUNIAS.—Sow in pans in a warm house, prick off when fit to handle and shade from sun.

PELARGONIUMS. — Strike cuttings from winter-flowering varieties and place in a started vinery. Give final potting to summer-flowering pelargoniums. Pot firmly. Pinch Regal type.

PERENNIALS.—Propagate by cuttings phlox, delphinium, aconitum, etc. "Hollow-stemmed" subjects need heat to strike the cuttings.

ROSES IN POTS —Prune hard back those potted last year. Ventilate carefully and guard against mildew. Spray with "Abol" to keep down pests.

SHRUBS FOR FORCING.—Keep temperature 55° at night. Syringe until flowering begins.

SUMMER BEDDING. — Agathea cœlestris: Strike cuttings now in heat. Abutilon: Shake out old plants, start into growth, and take cuttings from the young shoots. Heliotrope: Prune back spurs on standards, syringe and water and place in gentle heat. Salvia: Sow seed or strike cuttings. Acacia lophantha: Sow seeds in heat and prick out soon. Dracæna australis and Grevillea robusta: Sow seeds in heat. It will take two years before either of these are ready for bedding. Cineraria maritima: Sow in heat. Take cuttings of ageratum, verbena and eupatorium.

SWEET PEAS.—Pot on those sown during the autumn. Stand in a cool, airy house. Pinch back growths after a few days.

FRUITS AND VEGETABLES UNDER GLASS.

FIGS.—Thin young growths.

MELONS.—Top-dress seedlings. Prepare beds of fermenting materials over the pipes. Place a small quantity of brick rubble over this, then three layers of turf and on top a mound of compost consisting of loam, lime, rubble burnt ash and charcoal. Complete beds in the house two days before planting. Never let temperature go below 65° at night. Keep floor and walls damp.

PEACHES AND NECTARINES.—Keep atmosphere dry when flowering. Pollinate with rabbit's tail at midday. Fumigate with nicotine to keep down aphis. Syringe when flowers set and damp down. Disbud young growths as they come away. Remove all shoots pointing to the wall or to the front. Leave growths which break at the base of the present fruiting wood.

VINES.—Disbud growths of early vines, leaving two shoots at each spur. Cease syringing when growths 9ins. to 12ins. long, but continue to damp down. Raise temperature to 65°. When flowering keep temperature 70° at night and the atmosphere dry. Start the muscats by closing the house and syringing.

STRAWBERRIES.—Bring in another batch to form a succession. Discontinue syringing as they come into bloom. Pollinate artificially. Give soot water and artificials in weak doses.

ORCHARD HOUSE.—Start into growth by closing the house for one week. Do not excite the buds. In ten days raise the temperature to 45°. Syringe until the trees are in bloom. When flowering give dry conditions and more heat. Pollinate artificially.

CELERY.—Sow in boxes, place in warm temperature. Prick out in fairly rich compost and keep near the light.

CUCUMBERS.—Pot on, only half fill the pot. Top-dress in three weeks time. Keep temperature high and atmosphere moist.

DWARF BEANS.—Pot up in fairly rich compost.

MARROWS.—Sow in 3in. pots during the first week. Temperature 65° at night. Place near the glass when germinated.

MUSHROOMS.—Make up fresh bed.

POTATOES.—Top-dress and stake those in pots.

SEEDLINGS.—Prick off into boxes cabbage, cauliflowers, onions and leeks.

TOMATOES.—Prick off into boxes containing a sandy compost. Grow sturdily.

OUR SEED NUMBER

THIS is a special number of THE GARDEN devoted to plants catalogued in those elaborate lists issued by seedsmen throughout the country. For every gardener this is the most important time of the year, when these lists are p red over and the merits or demerits of plants and varieties listed are discussed, for, however much of a specialist you may be, these lists catalogue the solid backbone of a garden, the vegetables to eat and the flowers for massed effect and for house decoration.

I should like here to give credit to those to whom credit is due, the seedsmen, for it is largely owing to their zeal and skill and courage that our gardens are what they are to-day. No doubt this has been said thousands of times before and infinitely better said than I can, but I can speak from an amateur's point of view with the additional advantage of having had a peep behind the scenes. Few people realise the labour that is involved in a seedsman's business, the constant testing of seeds, the improvement of strains, the care taken in cleaning and packing the seeds, the organisation required for distribution, the long hours spent in making the catalogue as perfect as possible. I will state frankly that only a year or two ago I scoffed at the number of new varieties that were constantly coming on the market, but I see now that introductions of new strains are a necessity. For one thing people are inquisitive and demand something new, which brings one again to the question of supply and demand. Another reason, and the main one, is that the constant aim at improvement is the main antidote against slackness and retrogression, both in the plants themselves and in those who sell the seed. If the same varieties were placed on the market year after year, not only would there be deterioration in quality, which certainly occurs in plants of such complicated parentage as most of our garden vegetables and flowers, there would be little or no competition among the growers, which in time would just as certainly bring about carelessness in selection. As it is, our seedsmen have a right to feel proud of themselves, for the quality of the goods they sell is unrivalled throughout the world. Everyone who has friends living abroad hears of this again and again.

An American wrote the other day that, although he had travelled all over the world and was passionately devoted to plants of all kinds, those which lingered in his memory were the sweet peas, and the stocks, and the hollyhocks, and the roses, that he saw in this country. He said that they looked better and smelt better and were more satisfactory than in any other part of the world.

I think that is fair praise and that on the whole we are successful gardeners, but there is such a thing as having too much of a good thing. In gardening, as in everything else, it is the ordinary solid gardener, who works away quietly, who is the backbone of the profession. A friend told me the other day that she objected to amateurs showing at horticultural shows and refused to show plants herself, for it meant that unless the gardeners were exceptionally broad-minded and level-headed a plant or a few plants would be nursed and coddled to the exclusion of all others. There is a great deal of truth in what she says, for gardening should not be a selfish profession, still less a selfish hobby.

Annuals by their very profusion are accustomed to be treated too light-heartedly. To be a really successful raiser of annuals requires just as much skill and attention as any other plant in the garden, which is a point that is not often realised. Frequently, annuals are used as a last resort to fill up awkward spaces in gardens. Although they are useful in this respect, yet their use should always be part and parcel of the original planning for effect in a garden, and a generous amount of ground should be allowed for their cultivation.

I can only hope that this will be a more successful gardening season than 1924 and that we may catch an occasional glimpse of the sun. At any rate I wish everyone the best of luck with their gardens.

E. H. M. C.

NOTE

The Council of the Royal Horticultural Society have asked Fellows to give their opinion on the Sunday opening of Wisley, on a post card which is inserted in the book of arrangements. We hope that Fellows will not overlook this post card in the more congenial occupation of making their selection from the list of surplus plants, and will give as their opinion that Wisley shou'd be opened to Fellows on Sundays.

AMONG OTHER ARTICLES IN OUR NEXT ISSUE WILL BE:

MODERN LUPINS.

THE UPKEEP OF A LAWN, by Reginald Beale.

EAST LOTHIAN STOCKS, by W. F. Rowles.

HOW TO HAVE AN EARLY FLOWER GARDEN, by Helen Colt.

REPORT OF THE ROYAL HORTICULTURAL SOCIETY'S FORTNIGHTLY MEETING.

SOME FAVOURITE ANNUALS

IN a book on general gardening, written for the guidance of the novice, the writer warned his readers against the sowing of many annuals, which often, he said, have a brief season, quickly become unruly, tumbling over their neighbours and, especially, injure the more valuable perennials by trailing over them.

As may be imagined this was written well over a quarter of a century ago, when hardy annuals generally were the Cinderellas of the garden, and, unlike the heroine of the fairy tale, had no godmother to arrange even a brief hour of triumph. Slightly to paraphrase "'Twas true, 'tis a pity; 'tis a pity, 'twas true." But, here, the writer confused cause with effect. One can easily imagine the annuals of his day. Nearly always they were sown far too thickly and were rarely thinned. Under such conditions small wonder that their flowering season was short and that the plants tumbled about.

Given fair treatment there are many hardy annuals that are most valuable border plants, for they produce a succession of delightful flowers which add immensely to the border effect and they are also invaluable as cut flowers. But it is not sufficient simply to rake over a piece of ground and scatter a few seeds. The soil preparations should be just as thorough as for any other type of plant.

As a rule the best results are obtained when the seeds are sown in pans or boxes in moderate heat early in the spring—from the end of February onwards is a good time—and after having been pricked off singly, and duly hardened, are planted out permanently during the latter part of May. While

NO GARDEN IS COMPLETE WITHOUT CHINA ASTERS.

FEW PLANTS ARE MORE EFFECTIVE THAN GODETIAS.

under glass, abundance of fresh air should be given, whenever the weather conditions permit, otherwise there is a danger of the seedlings damping off.

When facilities do not exist for raising the plants under glass, excellent results may be obtained from seed sown in their flowering positions, provided the seed is sown thinly and the plants are rigorously thinned out at intervals until they are finally planted out quite a foot apart. From the middle of March to the end of April will be found to be the best time for sowing annuals out of doors for summer display.

Sowings for succession of bloom are often recommended; this is the counsel of perfection, but it requires more garden space than can usually be afforded. It should be borne in mind that seed-bearing is the end and aim of a plant's existence and that when seeds are formed there is no further need for flowers. Therefore, to prolong the flowering season, the seed vessels should be removed as soon as they are seen.

Clarkias and godetias are becoming increasingly popular, and as they have much in common, they may well be considered together. Both flowers fall naturally into two sections. The tall varieties bear their flowers in long, loose sprays and become 2ft. or more in height, while the dwarf type are of more formal habit, flowering in denser clusters, and these grow about a foot high. No one who has seen the long rows of dwarf godetias in the seed trial grounds at Reading, Raynes Park and elsewhere could fail to be enchanted with the glowing masses of satiny blooms of all possible shades of colour. Such plants as these are only to be obtained when each individual is allowed quite a foot of space. The tall varieties of both clarkia and godetia may be planted a trifle more closely together, though if their graceful sprays of lovely flowers are intended for cut blooms they should not be overcrowded, as the cutting tends to induce branching and consequently more dense plants.

Although they are closely allied, it will generally be found that the clarkias prefer a more moist situation than the godetias, though both will thrive in any good garden soil.

Formerly it was becoming the fashion to give varieties of annuals distinctive names, generally those of famous persons,

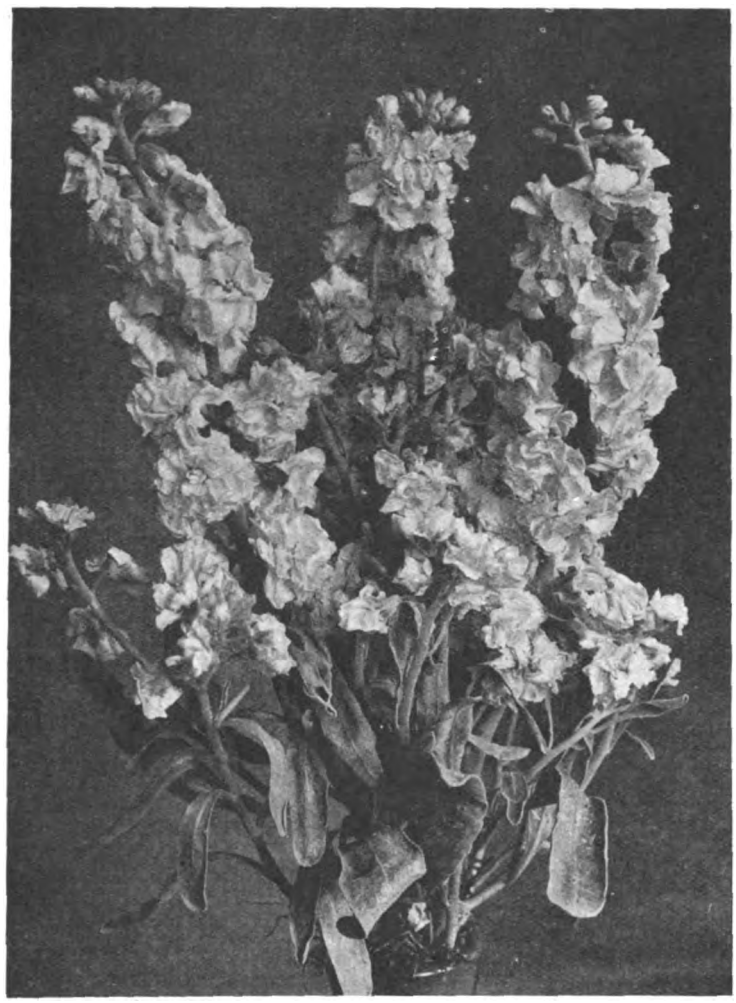
Digitized by Google

but more recently the saner method of listing the varieties under their colour name has become the vogue, and one may order the particular shades of colour required in full confidence.

Among recent novelties there are several clarkias well worth growing. Webbs' Double Rose is especially valuable and is even more beautiful as a cut flower than when growing in the garden. Carters' Brilliant Princess is another good double-flowered variety and its well formed flowers are of a clear warm rose colour. Among the pulchella varieties, which are dwarfer and bear their flowers in clusters, Sutton's Brilliant Rose stands out as one of the very best.

Godetias provide even a larger choice and with these the association of two such sorts as Sutton's Double Rosy Morn and the dwarfer single, Mauve Queen, will be found particularly charming. Carter's New Lavender is one of the loveliest of the newer godetias; its long graceful sprays are regularly furnished with single flowers of most charming colour. Lady Albemarle, which is sent out by Messrs. Robert Sydenham, is a large crimson godetia of the compact strain. A desirable novelty among the godetias is the Whitney azalea-flowered type which Messrs. Barr and Son have sent out. The flowers have beautifully waved margins and have much the appearance of those of the Ghent azaleas.

Although they have nothing in common, many people almost naturally associate stocks with asters, but while asters seem to succeed with nearly everyone, often the stocks are only moderately successful. This partial failure may nearly always be attributed to the lack of lime in the soil, and the best form of applying lime for stocks is as lime rubble. The ten-week stocks are mostly grown and these must be raised under glass to obtain the best results, although seed may be sown in the open ground towards the end of April. When the seedlings appear the very robust ones should be discarded as they are always gross, single-flowered plants of no beauty. It will be found that it is the smaller seedling which has leaves curving towards the stem that will produce double-flowers in good compact spikes. In the very best of strains there are bound to be a certain proportion of single-flowered plants if all are allowed to grow. When planting out stocks care must be taken to disturb the roots as little as possible, so that there shall be no check to their growth. Recently some new shades of colour have been introduced into the ten-week stocks. The Queen of the Belgians, a delicate silvery lilac, and Mauve Beauty, both listed by Messrs. McHattie and Co., are excellent examples, while Webbs' Snowdrift is one of the best whites. For earlier flowering one must grow the old-fashioned Brompton stock, which is a biennial. Messrs. Barr and Sons are offering seeds of the Old English Scarlet, Cottagers' White and the new White Lady among their Brompton stocks. These will be found to be of most delightful fragrance and appreciably earlier than the ten-week varieties.



FOR EARLY FLOWERING, THE OLD FASHIONED BROMPTON STOCK.

There are now a great many types of China asters to choose from; though the old favourite Victoria aster is still grown in great numbers by the market gardener because its dwarf compact habit permits it to be readily transplanted even while in full bloom. This type has immense colour value for the garden, but those who prefer more graceful flowers will grow the ostrich plume and the single-flowered Aster sinensis, both of which may be had in a variety of most charming colours. As wet weather asters none is better than the giant ray varieties, which also are excellent as cut flowers. The Southcote Beauty single asters are particularly graceful. Webbs' semi-dwarf Comet asters are also of considerable merit both for the garden and the house. For those who prefer taller flowers, Barr's tall chrysanthemum asters are to be recommended. They grow quite 2ft. high and are of branching habit. As with stocks, it is best to sow the seeds in a gentle heat at the end of March, pricking off the seedlings as soon as they can be handled and finally planting them out at the end of May. Where there are no glass facilities, it is often found that the single-flowered varieties do best when sown out of doors at the end of April. A. C. B.

THE NEW DAHLIA-FLOWERED ZINNIAS

ZINNIAS are one of the showiest and most brilliantly coloured of all the half-hardy annuals. In an open, sunny position planted in good clumps or masses the vivid colours of the zinnias afford a very effective display, lasting from July until well on into the autumn. Within the last few years these flowers have increased rapidly in popularity and have been greatly improved; new types have been raised and a large variety of most beautiful colours is now obtainable. The new dahlia-flowered zinnias which received the gold medal and an award of merit at the R.H.S. last July are exceedingly effective and can be used either for greenhouse decoration, in beds or borders, and are excellent for cutting. Fortunately, they are of easy culture, and treated in the following way give most successful results.

Sow the seed thinly in boxes about the first week in March in a mixture of old turf and well decayed manure, two parts old turf and one part manure. When the old rotten manure is dry enough to crumble up when rubbed between the hands, it is in perfect condition for mixing with the soil. A little sharp sand must be added to the compost to keep it sweet and porous. Place the seed boxes or pans in a warm greenhouse, keeping the night temperature as near 60° as possible, allowing it to rise a few degrees during the daytime. Give the boxes a good watering through a fine rose and keep the atmosphere moist. It will take from five to seven days for the seed to germinate. Gradually dry up the atmosphere and only water when necessary. As soon as the seedlings are large enough to handle prick them off immediately (using

Digitized by Google

the same mixture, as they damp very quickly, especially if the temperature is allowed to drop below 60°. The young plants should now be grown on in as light and airy a position as possible, guarding against cold draughts and over-watering. When they are about 3½ins. to 4ins. high, they should be strong and vigorous and ready for potting on into 3in. pots. It is advisable to keep to the same mixture, but pot fairly firmly with good drainage, as they make strong, fleshy roots and drink up abundance of water. From this stage there is not much fear of damping, as the growth is quite hard. In about a month or six weeks they will be ready for the final potting, which can be easily ascertained by turning out one of the plants. On no account must they be allowed to get pot-bound, for if this happens they form a premature bud. The aim must be to keep the plants growing on steadily. For the last potting use fresh loam, adding manure and sand in the same proportion as already recommended. This new giant dahlia-flowered zinnia is a very gross feeder, therefore it would be advisable to add a small 6o potful of Dobbie's Fertilizer or bone meal to every two bushels of the potting soil. Pot firmly and return the plants to a cool greenhouse. They will grow very rapidly in the new soil and make well shaped bushy plants about 18ins. across and 2ft. high. In hot, sunny weather they will require watering daily, and when the flowering buds begin to appear water every alternate day with weak liquid manure water and occasionally a little soot water. As a guide to beginners, during a spell of dull or wet weather it is a wise plan to rap the pots with the knuckles or a piece of wood. If the pots ring or sound hollow, the plants require water.

ZINNIAS IN VARIETY ARE INVALUABLE FOR A BRILLIANT DISPLAY OF COLOUR IN BEDS AND BORDERS.

The flowers open very slowly, but when fully developed are exceedingly handsome and of brilliant colours, ranging from cream, pinkish buff, rose, yellow, scarlet, crimson and orange and should be about 5ins. across and 3ins. deep. The blooms when cut last a long time in water and make an economical and handsome house decoration when arranged with their long stalks in glasses. Pot plants are equally effective, each individual bloom lasting about six weeks, thus every plant should give a brilliant display of flowers from two to three months and require no shading from the sun.

The zinnia, as well as being such a suitable decoration for greenhouse or conservatory, is also most valuable for planting out of doors in beds or borders. There is nothing, in my opinion, more effective than a large bed of dahlia-flowered zinnias either mixed or true to colour. The shades are so exquisite and brilliantly vivid that they attract the eye immediately

The seed for outdoor decoration should be sown about a month later than that for greenhouse work, as the zinnia grows very rapidly. By sowing too early they come on and are ready to plant out before all risk of frost is gone. They must on no account get a check while in the boxes, or they will run into flower, which will be detrimental to the constitution of the plant all through the growing season.

Anyone with a cool greenhouse sowing the seed the first week in April will have plants quite large enough to plant out the last week in May. The seed must be sown in light soil the same way as advised for pot work, but cover over the seed with a mixture of light soil and sand (half of each) if they are to be grown without any artificial heat. This will be a safeguard against damping, as the seedlings in their young stage are inclined to damp off. But if the house is kept on the dry side after the seedlings appear they will be quite safe, and after they are pricked off into the new boxes of fresh soil there should be no further trouble with regard to damping. The boxes should be placed as near the glass as possible and plenty of air given in the daytime in mild weather. For outdoor cultivation the plants break more freely if they are stopped once, say, ten days before planting out. They should be planted 18ins. apart each way for flower-beds and for planting in rows 18ins. from plant to plant and 2ft. from row to row. Zinnias do well in any good garden soil which has been dug in the autumn about 1ft. deep and enriched with a little farmyard manure. This should be forked over lightly in the spring and levelled. Light soil should be well tramped when in a dry condition in the same way as for an onion bed. After planting, it should be kept well hoed to prevent the ground from cracking until the foliage is large enough to shade the soil from the direct rays of the sun.

The zinnia comes into flower about the first week in July and continues to give a brilliant display till well on into the autumn. It is quite easily grown and anyone following the above instructions will be amply repaid. DONALD ALLAN.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its Readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2

SOME OF THE MORE UNCOMMON ANNUALS

FOR GARDENERS WHO WISH TO TRY SOME ANNUALS NOT OFTEN SEEN, THESE NOTES SHOULD PROVE OF VALUE. SOMETHING UNCOMMON CREATES AN ADDED INTEREST IN THE GARDEN.

"SOMETHING new" is ever the demand from the gardener, as from the rest of the world, and in the endeavour to satisfy this, fresh varieties of older flowers are pouring in a constant stream upon the market. An improvement in size or difference in colour, however, is only a variation upon the older, after all, and we would suggest that a far more hopeful avenue for exploration lies among the annual flowers and especially those that are not so commonly grown. Here, indeed, is a treasure-house, the key to unlock which consists of some yards of well tilled earth and a few shillings: for we will guarantee that you can obtain more "new"—new to you and your friends—flowers among the annuals than among any other class of plant. All annuals are divided into three classes—greenhouse, half hardy and hardy—and among each section we shall find species that just "fit the bill" as far as our present consideration is concerned.

Let us take greenhouse kinds first. These need a somewhat higher temperature than the half-hardy kinds—65° to 70°—and should be sown in February or March, great care being taken that they never receive a check. This may arise from two causes, lack of heat and attack by insect pests—due to lack of humidity in the atmosphere. These points should be well emphasised in the mind, because it is impossible to achieve success without adequate temperature and moisture where greenhouse annuals are concerned.

A quite unusual example of these plants that deserves to be well known is the tomato-fruited solanum, Solanum integrifolium—a rather tall-growing plant that makes a splendid display in a large house. The height is 3ft., and the flowers are followed by deep scarlet fruits shaped like the tomato, which last well on the plants as well as when the stems are cut for decorative purposes. A relative of this that might well be grown as its companion is the egg plant, Solanum Melongena, which may be regarded both from a decorative and a utilitarian point of view. From the decorative aspect the white variety is the most egg-like, but the Purple Round is the best for eating. The latter is very interesting and certainly crops earlier.

Still upon the subject of fruiting plants, do not overlook the gourds which, in a large house, may be used to great effect upon the roof and rafters. Especially striking among these is Lagenaria vulgaris, the bottle gourd, with its huge bottle-like fruits that hang so gracefully from among the handsome leaves. Another interesting form is Luffa cylindrica, the source of the loofah of the bathroom. This is a long tubular grower, which should be allowed to hang upon the vines until fully ripe and then cut and immersed in water until all the pulp has softened and can be washed away under a strong stream of water—there you have your loofah. Many of the small cucurbitas are also extremely decorative small gourds for roof coverings, and both these and the lagenarias may be grown outdoors by sowing later and hardening off. Hibiscus Manihot Sunset with its immense yellow flowers, 6ins. across, is another very handsome greenhouse annual of easy culture; while Torenia Bailloni with its bright golden blooms with brown throat is an unusual variant on the better known Fournieri.

Coming to the half-hardy annuals that may be raised in an ordinary greenhouse temperature by sowing in February and March, do not overlook the splendid new red miniature sunflowers, for these are most effective, both in the borders and when cut. The stems are long and the flowers produced in wonderful profusion, while the colour ranges from flesh pink to a deep coppery red. The height of the plant is 3ft. to 5ft., so that they are invaluable in mixed borders.

The tobacco is ever a popular flower, and grand subtropical effects may be produced with the variety N. sylvestris, which is certainly unusual. The foliage is of gigantic proportions, the flower stems reach a height of 3ft., and the long white tubular flowers remain expanded by day as well as night.

Calceolaria chelidonoides is a very easy plant to raise and makes a really splendid pot specimen of perfectly symmetrical form, smothered from base to tip with beautiful pale yellow flowers and pretty fern-like leaves that are perfectly distinct from the ordinary calceolaria. Sedum cœruleum is delightful as a pan plant and the seeds may be sown directly into this and, later, if required, the whole ball transferred to the open ground. The small fleshy leaves assume a lovely reddish tint when exposed to the sun, while heads of pale blue flowers form a very striking contrast. The Santa Barbara poppy, Hunnemannia fumariæfolia, though not strictly annual, responds to treatment as such and is a very beautiful plant. The foliage is greyish and finely cut, and the large orange flowers, that last well when cut, are superb.

Outdoors, the absolutely hardy kinds that merely require sowing where they are to bloom and subsequently thinning out freely to suitable distances apart, provide us with very large numbers of "unusual" flowers that are full of interest. A striking example of these of extreme brilliance is Venidium calendulaceum. This forms a dwarf spreading plant, half a foot high, with brilliant orange daisy-like flowers which continue to expand all through the summer and autumn. It is simply gorgeous for a band edging. One seldom meets Cerinthe major, a quick grower that soon begins to flower. The foliage is glaucous and the tubular yellow flowers are very attractive to bees. One is sometimes surprised to see a brilliant patch of forget-me-nots in the borders in August, and one wonders how a plant has so strangely missed its flowering season. There is only one species that will do this for us—Myosotis azorica—and the secret is to sow the seed in early spring and see that the little plants do not suffer from lack of water during summer. Flora's Paint Brush is a showy annual that makes no show in the border, although, when cut and placed in a small vase, it strikes one as a very vivid little flower. You will find this under "Cacalia" in the seed lists, and there are two species—

MASSES OF THE PALE BLUE FLOWERS OF SEDUM CŒRULEUM

Digitized by Google

one a vivid post-office red, the other orange-yellow. The stems are tall and thin, and each flower is exactly like a paint-brush that has been dipped in brilliant red or orange and held upright in the air.

For naturalising in steps or crevices between paved paths, a charming and unusual little annual is the violet cress, which has probably been kept out of general popularity by its botanical name—Ionopsidium acaule. The botanists persist in inflicting these terrors upon the lay mind, and annuals seem particularly favoured by their attention, as you will discover if you glance through a representative list; but, happily, we are not compelled to use them—or pronounce them. In this case the plant is a particularly charming one, forming dense tufts of foliage literally smothered with wee pale lilac flowers. It does better in damp and partially shaded places, and is apt to die out in paved paths if fully exposed to the sun, but in the angles formed by steps it is splendid. Equally good in similar positions, though capable of bearing more sun, is Leptosiphon hybridus. This does not exceed 3ins. in height, and rather resembles a mossy saxifrage, but with the cushions studded all over with dainty white, rose or yellow flowers. The seeds of this are extremely small, so that it is essential to make the surface soil very fine before you sow.

That old-fashioned favourite of the cottage garden, Impatiens Roylei, well deserves to be better represented in the present-day garden: though it must only be grown where there is plenty of space, for it is a rampant grower. The elegant pyramidal plant is topped by clusters of rosy red flowers at a height of 6ft. Even more effective is the variety White Queen. Nasturtiums with variegated leaves, dwarf and tall, are most striking where grown in poor soil—for this brings out the variegation in a marked manner. A wonderful grass that should certainly be grown is Coix Lachryma, or Job's Tears. The seeds of this are very large and sometimes used as beads. Calvary clover, Medicago Echinus, with its green leaves heavily blotched by a drop of "blood," and the wonderfully spined seed case that, unwrapped, forms a "crown of thorns," is a very hardy and most interesting annual. An annual anchusa is now obtainable, reaches a height of 18ins. and bears a profusion of valuable blue flowers for cutting. Loasa lateritia, though a climber, is dwarf—2½ft.—and bears striking orange flowers. The seeds should not be sown until early May.

For dry soils, Echium creticum may be recommended and will produce racemes of red flowers very freely. Among useful varieties for cutting in late summer is Rudbeckia bicolor superba. This covers itself with deep golden yellow flowers that are made even more striking by a central brown ring and disc.

Finally, do not miss Campanula macrostyla, one of the most "unusual" flowers of the family. This is not difficult to raise from seed, reaches a foot in height and produces cup-like flowers of a lovely lilac purple with darker veins, while, from the centre, a long style—from which the plant gets its name—protrudes in a striking manner.

H. W. CANNING-WRIGHT.

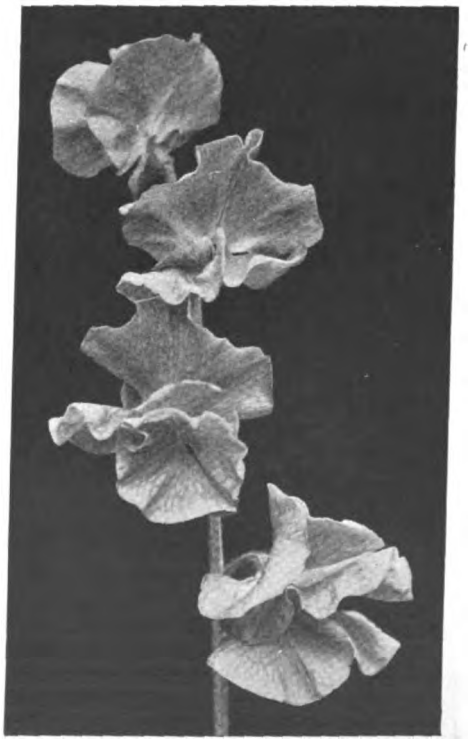
SWEET PEA NOVELTIES FOR 1925

So much has been done to develop the sweet pea that it would seem impossible to improve them further; and yet within the last year some new varieties have been produced which are actually superior to those already in commerce. What is needed more than new varieties is improvement of colour in those varieties which already exist; many suffer considerable damage by rain or sun. The blues turn pinkish mauve in wet weather, and the reds fade in hot sunshine. To the enthusiast new varieties are always acceptable; he hastens to obtain anything in the way of a novelty, especially if it possesses some unique point, such as a variation in colour or form. The exhibitor, too, is ever ready to experiment with new varieties, in order to find out if they produce by intensive cultivation superior coloured and larger flowers borne on longer stems than those which he has been lately growing.

Among the mauves there has been decided room for improvement, and we consider that the new variety, Mauve Beauty, raised by Messrs. W. J. Unwin, has achieved this. When carefully compared with the other mauves it is found to be of a clearer shade, cleaner and more uniform in tone. The mauve is deep and yet not in any way hard. This variety stands the weather well and is a vigorous grower, producing large waved flowers on strong stems. It is particularly acceptable on account of its sweet scent. Messrs. Unwin are sending out another novelty which is most attractive but by some people would be considered too pale in shade, the colour being silvery lavender-blue, which, although light, has a certain brightness owing to its fresh clear tone. This variety, named Blue Butterfly, is particularly useful for decorative purposes. Wembley, a beautiful new variety, soft lavender-blue in colour, was especially noticed at Chelsea Show last year. It is one of the best of Messrs. Bolton's sweet peas, and will probably be more popular than any other similar shade.

The most striking of all the new sweet peas is Pimpernel raised by Messrs. E. W. King and Co., Limited. Although it received an award of merit at the R.H.S. in 1923, it is not yet in general cultivation, as the stock has been limited. The vivid scarlet of Pimpernel is ideal, for even in the hottest sun it retains its brilliancy. This factor greatly adds to the value of the variety, for many of the reds fade in hot sunshine and so lose some of their charm.

The striped and flaked varieties have undergone considerable improvement during the last few years and are now being grown to a much greater extent, and more attention is being paid to the picotee-edged sweet pea. These types are fascinating and very effective for decoration. A good variety has just been introduced by Messrs. Henry Eckford. It is a giant white with a charming picotee edge of a rosy pink. The flowers are large and produced in fours on long, strong stems. This variety, called Betty, is very useful for general purposes, as it is of vigorous growth. A similar dainty variety, called Lady Gay, is being offered by Messrs. Unwin, and in some ways is superior to Betty, the flowers being more distinctive. The bright rose picotee edge is well defined and the wings and back of the standard are flushed and veined in the middle with rose. This variety should convince people who believe that only the self-coloured sweet peas are of real beauty, that there is much to be said in favour of the uncommon striped and flaked ones. Mrs. John Curwen, also raised by the same firm, is another variety which is distinctive in colour and gives a most pleasing effect. The ground of the petals is white and they are heavily flaked and flushed with pink. The large wavy flowers are sometimes produced in sixes and are borne on exceptionally long stems. Mrs. J. Curwen is excellent for exhibition and does not look muddled or poor in colour as do some of the flaked varieties.



ONE OF THE MOST STRIKING SWEET PEA NOVELTIES: PIMPERNEL, VIVID SCARLET.

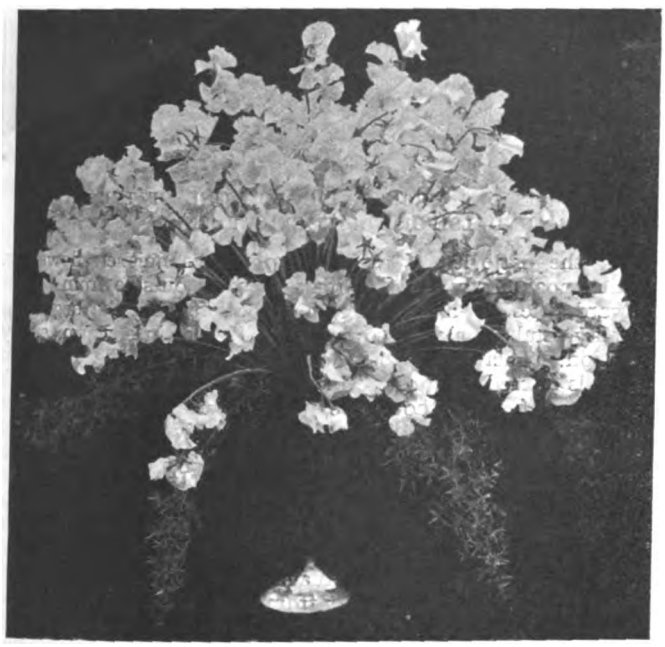
Remarkable in colour is the novelty Tom Sykes, raised by Messrs. E. W. King and Co. It received the first prize at the N.S.P.S. in 1924. This

Digitized by Google

variety should give great delight to the specialist, and is truly called a novelty. The standard is scarlet flushed salmon on a white ground, while the wings are scarlet-pink. The size and quality of the flowers are above the average, and duplex flowers predominate. Two good orange-shaded novelties are Mammoth and Guinea Gold —the former raised by Messrs. Bolton and the latter by Mr. J. Stevenson. Mammoth is a very rich orange verging on scarlet orange, and is very robust in habit. Guinea Gold is a delightful glowing orange which will appeal to many people for decoration. It will stand considerable strength of sun and wind. Both of these were selected varieties at the N.S.P.S. trials last year and received awards of merit. Another sweet pea raised by Mr. J. Stevenson is Coralline, a brilliant orange cerise, somewhat similar to Charming. It is vigorous in growth, large, and possesses a sweet scent.

Grenadier comes as a proof that varieties which were recently considered perfect have now been surpassed by a new introduction. Royal Scot was the best scarlet until Grenadier was put on the market by Messrs. Dobbie and Co., Limited. This new variety is fiery red, large and yet not coarse. The stems are of great length and the flowers freely produced. A good all-round variety also sent out by this firm is a rich ruby red. It is excellent in quality and has been named Ruby. Pamela and Sylvia have delightful combinations of colour and are two novelties raised by Mr. F. C. Woodcock. Pamela is a rich mauve shaded with rose over the standard, while Sylvia is a beautiful blue overlaid with a rose sheen. Both of these are of exhibition quality.

Of the new foreign varieties sent to us recently, Miss California, raised by Messrs. C. W. Morse, the American sweet pea growers, is undoubtedly the best. It received an award of merit at the N.S.P.S. last year and is one of the most charming and distinct of the pinks. It is a salmon shade of pink on a cream ground, the flowers are beautifully waved and borne on long strong stems. This variety is being distributed by the leading sweet pea firms in this country. A good many new varieties have been raised within the last year; some, however, will never stand the test of time, others are mere novelties and will pass out of notice as quickly as they gained favour, while a few promise to retain a position among the selected few.



SWEET PEA WEMBLEY, OF A SOFT PALE LAVENDER SHADE.

INTENSIVE CULTURE OF SWEET PEAS.

TWO GOOD WALL PLANTS

I WAS greatly interested all last summer in two plants growing on the south wall of my house. They are Penstemon isophyllus and the good scarlet form of Phygelius capensis. Both were planted in the summer of 1923 and trained up and tied in to the trellis on the wall. Penstemon isophyllus is not a very widely known species, and like so many of the family it is not always quite reliably hardy on a cold soil and in a cold winter. It is an unusually tall sort, extremely graceful, with long slender tube flowers of a charming soft, clear red which are marked inside with lines of deeper red, and it will go on producing these in loose spikes and with extraordinary freedom from early summer until late autumn. In the open border it will reach a couple of feet or more in height, but trained up my south wall it has more than doubled this. Its main stems have ripened in the wall-reflected warmth and become woody. The only attention it has had has been to cut away the rather bushy growth which developed at the base, so as to encourage top growth, and then as the plant grew I tied the branches in to the trellis.

P. isophyllus as a wall plant was purely an experiment on my part, but it has turned out, so far, a very successful one. What it may do if we have a real winter is another matter, for Stevenage is a cold place. But it will be interesting to see how high the plant may grow next summer, and I can see nothing to stop its reaching 6ft. or 8ft.

Phygelius capensis, surnamed Cape Figwort, is a first cousin of pentstemon, and like Penstemon isophyllus is a good plant all too little known. It is almost invariably grown in the herbaceous border, when it is far better grown up a wall.

As a border plant Phygelius capensis makes a forest of erect, glossy leaved stems about 2ft. high, each of which carries in late summer a whorled spike of orange-scarlet yellow throated blossoms, not unlike those of a pentstemon. Grown in the open border it is purely an herbaceous plant, the stems dying down to the root each winter. Excellent though the plant is in the border, it is infinitely finer when trained up a wall. It then grows much more rapidly. It is best to thin out all but three or four main shoots so as to throw every ounce of vigour into these. In the greater warmth which the wall gives they will ripen and become quite hard and woody, and will not die back as they would in the herbaceous border. My own plant ran up to 4ft. in 1923, and starting in the spring of last year, where it had left off the autumn before, it went on up to 9ft. For three months last summer it was covered with its immense flower spikes and was really a splendid sight.

There are two distinct forms of P. capensis in cultivation. In the commonest and most usually grown variety the flowers are rather a heavy, dull brick red, good, but not nearly so good as the coccinea variety, which is a lively vermilion scarlet.

CLARENCE ELLIOTT.

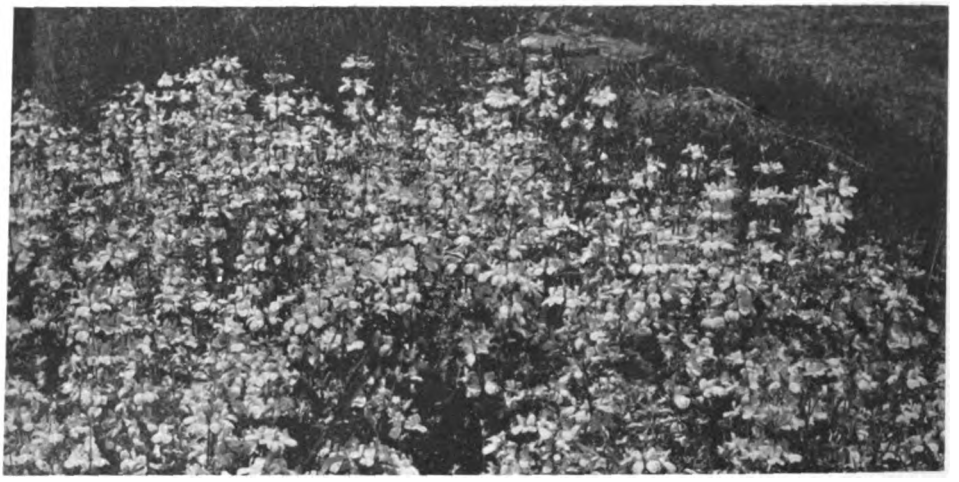
ANNUALS FOR THE ROCK GARDEN

FOR PROVIDING AN ATTRACTIVE DISPLAY IN THE ROCK GARDEN IN THE SUMMER MONTHS, MANY OF THE ANNUALS DESCRIBED IN THE FOLLOWING ARTICLE WILL BE FOUND INDISPENSABLE.

AMONG annual plants which can be grown from seeds each year the great diversity of form and colour is such that they play a most important part in the decoration of the garden, either in the form of masses in the flower border or in the rock garden. Many of them are easily grown and require little attention after the early stages of their existence, and these are among the more showy kinds. The effect produced by a broad stretch of the Caucasian poppy, China aster or eschscholtzia in full flower is a most striking one, but in the rock garden space is limited, so one has to fall back on the smaller and more compact-growing kinds. To produce the best effects many annuals require to be sown in the autumn, when they form small plants before winter, and in the following spring are ready to push forth their flowers directly the weather is favourable. By sowing both in autumn and in the following spring it is possible to have a succession of many of the individual kinds throughout the whole season.



THE GRACEFUL WHITE FLOWERS OF COLLINSIA BICOLOR, ONE OF THE MOST ATTRACTIVE OF ANNUALS FOR THE ROCK GARDEN.

The chief conditions required by annuals include fairly rich, well worked soil, and plenty of room for development. Many annuals are sown far too thickly, and are not thinned out early enough or sufficiently, the result being thin, weedy-looking plants with flowers inferior in size. Thinning should be done thoroughly, and as soon as the seedlings are large enough to handle. Sufficient room should be given to allow for the full development of each one that is left, and good sturdy plants will be formed. After this operation is performed little more attention is required except to keep the ground clear of weeds and watering in dry weather.

In the rock garden annuals may be used as a groundwork for bulbs, and for furnishing the bare spaces after the bulb foliage has died down. There are also many bare patches and corners which may be utilised for growing groups which will provide an attractive colour display during the summer months when the majority of alpine plants have finished flowering. While most hardy annuals may be sown outside from March onward, the half-hardy ones must be left until the beginning of May, and should be sown for preference in a warm, sunny position. There is plenty of choice among the numerous annuals offered by most seedsmen, but for growing in the rock garden preference should be given to the dwarfer and more floriferous kinds, of which a selection is given below.

A well known and charming little plant is Alyssum maritimum, commonly called sweet alyssum. It is only a few inches high, with sweet-scented white flowers in great quantity. A hardy annual, it comes up freely from seed sown in the spring, forming an excellent groundwork for taller plants. Very showy are the pimpernels (Anagallis), A. Monelli having large flowers which vary in colour from orange scarlet to rich blue, as in the case of our native A. arvensis. Although usually a biennial Erinus alpinus will flower the same year from seed sown early in the spring. It is a beautiful little plant for covering old walls and for establishing in the crevices of limestone rocks. The flowers vary from rose to white and are produced freely during the greater part of the season. Most of the eschscholtzias would be found too rampant for our purpose, but there is one species of dwarf tufted habit, E. cæspitosa, a charming little plant with rich yellow flowers. Emilia (Cacalia) flammea, the tassel flower, grows just over a foot high and bears tassels of brilliant orange scarlet flowers during the late summer months.

DIMORPHOTHECA AURANTIACA WITH ITS SOFT ORANGE FLOWERS GIVES FINE EFFECTS WHEN USED IN MASSES.

The campanula family provides two or three pretty hardy annuals: C. attica of very dwarf habit and flowers about half an inch in diameter, varying in colour from a rich bluish purple to white being the smallest. C. Loreyi is a beautiful species growing about a foot high and is for a long period covered in bloom. The flowers vary in colour from mauve-blue to white, and are 1½ins. across. Collinsia bicolor is a graceful annual growing about a foot high with rose purple and white flowers, while var. alba has pure white ones. Seeds sown in autumn produce plants which flower in May, while spring-sown ones flower freely in summer. The best species for sowing in autumn is

Digitized by Google

the blue-flowered C. verna. Both these plants come from California. One of the most brilliant annuals is Convolvulus tricolor (C. minor), which forms a spreading tuft about a foot high, covered for a long period with numerous deep blue flowers each having a white centre.

Dimorphotheca aurantiaca, the Namaqualand daisy, is a beautiful annual of bushy habit about 9ins. high. It has large daisy-like flowers of a salmon orange shade, with a black central zone. When the flowers are open in full sun it makes a very attractive group, one of the most brilliant annuals we have. A white-flowered kind is D. pluvialis, the flowers having a golden centre with the underside of the ray florets coloured a rich maroon. The erysimum family contains two good plants in E. Perofskianum (syn. Cheiranthus Allionii), about a foot high with brilliant orange yellow flowers, and E. linifolium (syn. Cheiranthus linifolius) with mauve-coloured fragrant flowers. The latter is really a perennial in suitable positions, but may be treated as an annual, and is very useful for naturalising on old walls. Downingia elegans is a very pretty annual growing to a height of 5ins. with narrow leaves with blue and white flowers not unlike those of a large lobelia. It is a native of California and belongs to the campanula family.

The gilias, also known as leptosiphon, are among the most charming of all annuals. Many of them form dense little bushes covered with numerous bright-coloured flowers. One of the smallest is G. aureus, with bright yellow flowers about half an inch in diameter on plants about 4ins. high. G. androsacea, with rosy lilac flowers, is slightly taller than the last, and of the same tufted habit. Gilia tricolor grows about 9ins. high and bears lavender-coloured flowers shading to white. All these are Californian plants and like a warm, sunny position. The violet cress (Ionopsidium acaule) is a charming little Portuguese annual about 2ins. high, forming dense tufts of violet-coloured flowers in early spring from autumn-sown seeds. Spring-sown seeds come up quickly and soon develop into flowering plants. A choice plant for the rock garden associated with even the choicest of alpine plants, it never becomes aggressive, and is particularly suitable for sowing in the crevices of paved walks or rugged steps. A good bee plant is Limnanthes Douglasii, either for sowing in autumn or spring. It is only half a foot high, with beautiful yellow flowers edged with white, and may be had in flower during the whole season.

Many of the toad flaxes (linaria) will be found useful for this purpose, as the annual kinds are all dwarf in habit and very floriferous. L. maroccana has flowers varying from dark violet to pink, crimson and yellow, all with a blotched lip. A. reticulata is a maroon scarlet with a golden blotch, while A. saxatilis is rich yellow. One of the most brilliantly coloured of all summer annuals is Linum grandiflorum, with glowing crimson flowers on tufted plants about a foot high. It is half-hardy, and should not be sown till April. The Virginian stock (Malcomia maritima), a well known favourite, may be had in various shades of colour, ranging from mauve to crimson and white. Matthiola bicornis, the night-scented stock, should be grown for its delicious perfume, which is specially noticeable after a shower of rain. A brilliant little half-hardy annual is Mesembryanthemum tricolor, with a more or less procumbent habit and ascending branches. The large flowers, 1½ins. in diameter, bright rose at the tips, shading to white in the centre, are produced very freely in a warm, sunny position.

Trailing, spreading annuals are the nemophilas from California, the best of which is N. insignis. Its flowers are over an inch in diameter, bright sky blue with a white centre, while there is also a pure white variety. N. atomaria has white flowers not so large as the above, with small dark spots. N. discoidalis is very distinct, with maroon flowers, the petals of which are edged with white.

Phacelia campanularia is one of the very best blue-flowered annuals, growing to a height of 6ins. or 8ins. and forming little tufts of light green foliage. The flowers are bell-shaped and of the most brilliant gentian blue colour produced in succession over a long period. For producing brilliant patches of colour very few plants equal the sun plant (Portulaca). It is a half-hardy annual, and should be sown towards the end of April in light, dry soil in a sunny situation. Numerous varieties in all colours are offered by seedsmen with both single and double flowers. For naturalising in odd corners in the rock garden Saxifraga Sibthorpii is a bright little plant with its rich yellow flowers, while a charming companion for it is the blue sedum (S. cœruleum). The latter is only half-hardy, of creeping habit, with dainty racemes of delicate lilac flowers during the summer months. Another blue-flowered plant is Veronica glauca, which is best sown in the autumn.

Many other choice annual plants might be mentioned which would be found useful, but from the above one could select sufficient material for use in furnishing all the bare spaces that occur now and then in the rock garden. By judicious arrangement of the plants also, a bright and continuous display of colour can be had in the rock garden over a prolonged period, which adds joy and considerable pleasure both to the raiser and the onlooker.

W. IRVINE.

NEMOPHILA INSIGNIS FROM CALIFORNIA, ONE OF THE MOST BEAUTIFUL OF SPREADING ANNUALS, WITH SKY BLUE FLOWERS.

GARDEN COLOURS

USEFUL ADVICE REGARDING COLOUR IN THE GARDEN. THE AUTHOR IS BOTH AN ARTIST AND A GARDENER.

IN the noble army of gardeners there are some regiments whose chief interest is in the individual plant; others whose first thought is for the effect of plants together in the garden. Neither regiment has any occasion to throw bricks at the other; but before I begin writing about garden colour I will try to pacify possible brick-throwers by saying that I agree that what little is written about garden colour is in large part tosh. (I except, of course, Miss Jekyll's famous book, and have not yet read Mr. Tinley's.) I agree, too, that the gardener who has no keen love for plants and their individual ways might as well take to house-painting: and I confess that if anyone offers me some marvel of a plant from Kamschatka or Peru I can hardly ever resist accepting it, even though I haven't the foggiest idea what company to put it in.

It is perfectly true, of course, that the Peruvian plant, if it happens to be so accommodating as to grow under the same conditions as the Kamschatkan, will generally look quite bearable beside it: but everyone who is not content with that hazard is to some extent a player of the colour-gardener's game.

The commonest defect in garden planning is certainly lack of simplicity; and this is specially true of the use of colour; and the problem of simplification becomes insuperably difficult if one piece of ground has to hold not only all the plants from Peru to Kamschatka, but also to combine those that flower from January to December.

"A blaze of colour all the year round." That is a common ambition for the whole of a mixed herbaceous border. But I am convinced that the best plan, even in a small garden, is to sort out the plants to some extent, so as not to waste the effect of their association. If you have Lilium croceum, say, growing near Clematis recta, they will make better effect than if they were apart; and if you bring a pure blue delphinium or anchusa into their company, you will find an added quality in each.

DELPHINIUMS IN THEIR MANY SHADES OF BLUE AND PURPLE.

Begin, then, I should say, by sorting out, and then go on to plant enough of one thing—or, at any rate, enough of one colour—to make a clear impression. To plant enough of one plant: that is always the difficult task. And it is remarkable how much of one good plant the eye can stand without finding it monotonous: Erica australis, say, or Rhododendron ciliatum, or Poet's Narcissus, or even aubrietia. One has also to learn what are the colours that really do hang together: for instance, Ceanothus Gloire de Versailles with Aconitum volubile and Clematis Perle d'Azur, or with Echinops humilis: Escallonia langleyensis with red valerian: or, at this moment, Rhododendron mucronulatum, with its gay rose-magenta, repeating the colour of Cyclamen Coum at its feet. Miss Jekyll has written of the effect of snapdragons with valerian of the same colour: the differing textures giving a pleasant effect as cut velvet does; and this is a very simple kind of colour harmony to look out for.

Then come the sequences of the same colour in varying tones. I am sure that is a kind of colour harmony not nearly enough considered. Take a spray of Thalictrum dipterocarpum, say, and put it against the velvety darkness of Clematis Jackmanni superba, or Sparks' Aconite. The depth of violet-purple in the one is beautiful in relation with the paler tone of the other. A great deal can be done in this way to give emphasis to the weaker colours—make them sit up.

With the mixing of different colours the game begins to get more difficult. Try, this spring, when the scillas and chionodoxas are out, picking a scrap of each flower available and sorting them into two or three companies. You will find, I think, that there is a series, culminating in the intense cerulean blue of Scilla sibirica, which does not mix well with the other pinker blues, such as hepatica or Anemone blanda. Keep these blues a little apart if you can; but there are plenty of colours that you can mix with either of them; the common primrose's yellow, for instance. Distinct from these there will be a violet series, including Iris reticulata and Crocus Tomasinianus; and so on.

Well, apply that principle to the summer garden. When the purple-blue Geranium platyphyllum is out, see what belongs to its company; the lupins and pallida irises, and the cool pinks and yellows of that season. And see where Thalictrum purpureum looks best: by itself, perhaps, with Lonicera syringanthus, or with spiræa, in some half-shady place. For there are many violet and purplish flowers that look best in shadow: magenta phloxes, for instance, and the bluer rhododendrons, such as Augustinii and hippophæoides.

When the delphiniums come, try the "matching" game again. (Yes, I know some people may smile if they find you at it, but it is a very good game all the same.) Some people like mixing all the purples and blues together, but, personally, I like to keep the pure blues, light and dark, separate from those touched with pink and purple. The purple delphiniums, such as The Alake, are in one series, and the pure sky blues, such as Blue Bird and Lord Lansdowne, in another: and the latter certainly require contrast, such as the clear yellow of tree lupin or Harkness hybrid mullein, to give them their full colour value. Do not be obsessed by a phrase such as the "blue border."

After the delphiniums come eryngiums, with their lovely equivocal blue: they are invaluable as a foil to the oranges and yellows. Try, for instance, the effect of E. Oliverianum of Alstrœmeria aurantiaca major, or Lilium pseudo-tigrinum, or montbretia, or Potentilla Friedrichseni (a valuable pale yellow shrub for the mixed border).

Then there are the plants that keep company with lavender, such as echinops and pink phlox, and Clematis Jackmanni superba, a plant which deserves a chapter to itself. Thalictrum

Digitized by Google

dipterocarpum is another plant to make plans for: and so is Salvia nemorosa, which makes a fine accent of strong colour in the company of silver asters and cool pink lavateras, hollyhocks, anemones and clematis. Buddleia and ceanothus, too, can be made the chieftains of new companies, grey-blue with pink and yellow, or purple and pink and grey.

I have not got to the brightest colours yet, the red-hot pokers and bergamot and pentstemon. But I must stop. One word more. There is a lot more to be done by studying the colours of leaves. Too often, for instance, the colour effect of beautiful grey leaves, such as Rosa rubrifolia, Senecio compacta, Teucrium fruticans or Cotoneaster pannosa, is wasted by being too much divided up.

Design is only one part of gardening: the kind of design I have been speaking of has the merit of helping one to appreciate and profit by the happy accidents. A PAINTER.

CROP ROTATION

BY EDWIN BECKETT.

WHEN one takes the opportunity in what may perhaps be a few idle moments, mentally to survey different aspects of horticulture, it is impossible not to be surprised at how little is really known of this great and important science, so necessary to life. It is forced home on us that the whole matter is practically even now only in its infancy, and that there is an enormous amount of research work due, if the world is to benefit in this matter, as it should. Crop rotation is one of the phases of which we really know but little yet, though no doubt, in generations to come, this will be a very important feature in the industry. It is as well perhaps to emphasise how little we know, as a whole, on these matters. Some time ago, I remember reading of a series of experiments that had been carried out, I believe in America, from an agricultural point of view, in connection with rotation work for cereal crops, and these had occupied not less a period of time than *thirty years*. Consider that period, and then see if anything like this has been done anywhere for horticulture. One of the determinations of this experimenting was to fix the fact that, generally speaking, the interval that should be allowed to elapse before a crop was returned to any particular area, was four seasons, and it was found that a lesser time correspondingly decreased the yield from the area. Now, though we may say that this was for cereals, yet the fact is just as important for vegetable crops, and though it may not be convenient to wait for four years before growing certain vegetables again on the same site, yet the example quoted emphasises the fact that the need does exist for some systematic dealing with vegetables in this way.

Let us for a moment consider the reasons for this changing about. There would appear to be two: the first being that crops will, to a greater or lesser degree impoverish the soil of the food constituents that they require, and for the process of allowing renovation of "Mother Earth" to be accomplished, other crops should occupy the position, such as will find their nutriment in other elements of plant life that is contained in the ground. Second, one must not overlook the fact that there are diseases that affect some plants and do not affect others, and therefore, should one grow crops that will be weakened by the absence of their proper food, they will the more readily fall a prey to their foes of disease, and, of course, this is the more urgent when it is found that a crop is affected by a disease, for it would be little short of madness again to use the same piece of ground where disease is present in active being.

It may be taken as an axiom that practically all vegetables dislike cultivation for two successive seasons on the same site, and I generally advocate that this repetition should be avoided for at least two years, so that two seasons intervene between the time when a plot is first employed for a crop, and the next period of cropping with the same thing, and as this requires a certain amount of plotting and planning to accomplish, it is to be recommended that a careful gardener, who is prepared to take the proper interest in this matter, should prepare a rough plan of his ground, setting out just what kinds he intends should occupy certain spaces over a period of say three or four years. This will avoid the possibility of recropping within too short a time, if the ideas set out are carefully worked to.

In furtherance of this idea, it will be found that certain crops afford a good follow on for earlier ones, on the basis of the suggestion previously set out, that one crop will leave or reject certain food elements, that the following one will utilise to its full advantage. For an example or two, we have stump-rooted carrots as an ideal follow-on after the early potatoes have been lifted, and when the carrots have been cleared after reaching the desired stage of maturity, then cabbage can well occupy the same site. Thereafter, needless to say, do not occupy the area with a further Brassica family member, for this is the same group as the cabbage, and they very strongly resent following one another, and frequently fall victims to "club-root" disease where this is attempted. Onions, however, would form an excellent next crop, and then, for the third season, something quite different, such as a leguminous crop could take possession of the site. Another excellent succession is formed by first planting celery, a crop which so greatly benefits the condition of the soil, and renders it in fine fettle for peas to follow. Then for the change of class again, either leeks or winter greens can occupy the site, such, when cleared being followed by a crop like potatoes. Several useful combinations can, after this manner, be worked out, and the usually harmful practice of succession thus be avoided.

Just a little modification of the idea is now desirable, for it is not an inflexible rule, as there are a number of crops, that even if they are a trifle adversely affected, yet may well be grown on the same site for a number of years, and especially if all due attention is accorded the soil by proper trenching methods, and application of manures and fertilisers. These are leeks, onions, shallots, carrots, horseradish and artichokes, both globe and Jerusalem. Potatoes too can also be grown on the same site in this way, but the attention in the way of trenching and food is even more necessary for these. In this way we have grown potatoes, on what is an ideal site for these, continuously, over a period of forty years, for exhibition work.

Reference has been made once or twice to plant food, and in the foregoing schemes for rotation, as set out, this point must not be overlooked in conjunction with the allied subject of soil movement. The requisite care, in the application of suitable manures, fertilisers, and above all lime, must also be properly considered and dealt with, as well as the working of the ground.

Just a final word in connection with the last remark. Some there may be who will find their piece of vegetable garden perhaps too restricted to give this matter of crop rotation full consideration, and to such folk I would say that, where it is really impracticable, they should resort to real deep trenching, the deeper the better, as a corrective and preventive of the evils referred to, bringing the sub-soil up to the surface; keeping in mind that the plants want proper food, suited to them and that "any old thing" in this way, will not do.

A PRETTY JAPANESE COLUMBINE

WHILE it has not the stature and commanding charms of the tall hybrid columbines so justly held in high admiration, Aquilegia flabellata, a charming Japanese species, has its own attractions and has a special value for those interested in their rock gardens, where the hybrids would be out of place. A. flabellata is a most attractive dwarf plant, which grows about 9ins., or, occasionally, a foot in height. It has pleasing leaves and pretty flowers, which are large for the size of the plant. They look well on the plant and form an attractive feature of the rock garden. Personally, I like to have it as dwarf as possible, and I can secure this by planting it on poor hard soil, with the result that it grows only about 6ins. high. The flowers are of a good blue, but there is a still prettier white variety, A. flabellata alba, which I have found come almost invariably true from seed. The typical blue form can also be raised from seeds, which germinate well if sown in spring, either in the open or under glass. It will thrive either in sun or shade, a good quality which helps greatly to make it more valuable to the many. S. ARNOTT.

CORRESPONDENCE

DESTRUCTION OF SNAILS AND SLUGS.

SIR,—Mr. F. C. King, on page 65, asks for opinions concerning ducks for ridding gardens of the above named pests. From my experience here, I say that the food of our familiar waterfowl first and foremost is the worm. We are often told to keep ducks to rid us of slugs, but I seriously think that no duck will touch them, if it can possibly find something more agreeable. When my man and I are digging, the ducks are usually there and hardly a single worm escapes. Often a slug is unearthed and thrown to my three or four ducks, but I have never seen one touched. Reluctantly, therefore, I hardly believe in the efficacy of ducks concerning snails and slugs. May I say they are fonder of a half-grown frog if it comes near enough.

As regard Mr. A. D. Richardson's powdered alum cure, like Mr. King I am sceptical. I strongly advise Mr. King, therefore, to cling to his practical means and not bother much over the more or less scientific ones. I do not say for certain that the duck when nosing about under leaves, weeds, etc., does not take an occasional slug, but I am convinced it prefers other delicacies.—R. MORTON.

SIR,—In your issue of January 31st Mr. F. C. King asks about ducks as slug-killers in a garden. I have had a pair of wild duck in mine for many years. I should be very sorry to part with them. They are quite the best "remedy" I know for slugs. The damage they do is very slight, and they practically rid the garden of slugs. They are very tame and ornamental. I think the ducks should be wild duck, or a similar size; the large, heavy duck might paddle the soil a good deal.—BASIL SPRAGGE, *Lockerbie, N.B.*

SIR,—My experience with these pests may be of interest to your readers. Living in Cornwall with a garden surrounded with loose walls and hedges, there are plenty of slugs to be caught. About six o'clock all last summer I placed small heaps of bran around the garden in those places where I had noticed the slugs were most troublesome. After dark I went out armed with a lantern, an old saucepan half full of ordinary salt dissolved in water and a pair of forceps. All I had to do was to visit the heaps where the slugs had forgathered to feed, pick them and pop them in the salt with the satisfaction of knowing that each one caught was really out of the garden for good. At this time of year I place the bran under a slate or a piece of board and collect up the harvest of slugs in the morning, this being less unpleasant than turning out of a night. As to the question of powdered alum, speaking as a chemist I see no reason why this should act in any way different from common salt, and most certainly would require renewing after rain.—EDWARD CAHEN.

SIR,—The encounters of your various readers with slugs are read by me with so much sympathy, and I hope my own experiences may be a help. When we made this garden some years ago it was overrun with slugs. We are on the very edge of Dartmoor, and they descended on us in thousands of every size and complexion and all equally ferocious. No snails, luckily. We had almost given up hope of delphiniums and other rather favourite plants, as the slugs sat by and ate shoots as they appeared, if not earlier. But one spring, just by chance, my husband turned about a hundred baby chicks two or three days old into our kitchen garden, where my flower borders mostly are, with a brooder for shelter. They set to work and cleared the whole garden in no time, and grew and flourished in consequence of so much food. Now we always put the first brood or two there. They do no harm, and it is delightful to see them turning up every leaf and hunting up all the insects. Nowadays there are no slugs at all of any kind, and very few woodlice or earwigs or any insects. Directly the chicks begin to scratch the soil about we move them out into runs and put in another lot. Incidentally, they cleared the garden of white stone crop which at one time threatened to smother everything. Many people hatch out a few chickens each spring and could do as we did. We tried ducks, but they did far more harm than good, but the tiny chicks hurt nothing.—NORA GILOART, *Devon.*

SIR,—A method of dealing with the above pests which I have found of service in reducing their numbers is, when pulling up the various members of the Brassica family when their season of usefulness has come to an end, to place the greenstuff in heaps on the ground on which they have been growing and also on other parts where it may seem desirable, chopping up such things as Brussels sprouts to make them lie closer together. These heaps, if left for several days, will attract numbers of slugs, which can be readily exposed by turning the vegetable matter over, when a thick coating of soot can be applied, which destroys them. It is well to use the soot very freely, as the slugs have much less chance of escaping than when a mere dusting is applied, and the soot can be spread about after it has accomplished its purpose in killing vermin, as it forms an excellent fertiliser for the soil. Kainit, or other potash salts or common salt, might be used in place of soot with good effect. Professor Cousins, in his most useful little book "The Chemistry of the Garden," says: "Soot, when fresh, is a useful garden remedy for slugs, and being a general fertiliser, is often of valuable assistance to the gardener. Dust the soil with soot until it is quite black." A good way is to apply the materials direct on the slugs when they are feeding either in the early morning or late evening.—R. W. DEAN, *Basingstoke.*

[A correspondent has sent us a copy of the *Gardening Bulletin* which gives a method of destroying slugs and snails. This is the method: "Take a half-gallon dipper. Fill it with bran. Pour the bran into a large bowl or tin. Add to the bran one teaspoonful of Paris green obtained from your seedsman. Do not use more than a teaspoonful. Ordinary painters' Paris green is useless. With a large iron spoon or other similar article carefully and thoroughly mix the bran and Paris green. Take plenty of time over this operation. Thorough mixing is essential. It will require a quarter of an hour to make the mixture thorough. Every small particle of bran will (if by thorough mixing it be given the opportunity) absorb a minute quantity of the Paris green. Choose a dry night for spreading the mixture, and spread it very thinly. Allow it to dribble thinly through your nearly closed fingers. One dipperful of bran should be sufficient for a quarter of an acre of ground. A little thought will enable one to see the reason why a thin scattering only is necessary. If thoroughly mixed, each tiny flake will, when eaten by a slug, destroy the eater. Slugs and snails are extremely fond of bran. If one could arrange for flakes of poisoned bran to lie on the ground at intervals a foot apart, it would be sufficient for our purpose."

A similar method has been sent in by "Nil Desperandum."—ED.]

BEDS OF ST. BRIGID ANEMONES.

ST. BRIGID ANEMONES.

SIR,—I enclose a snapshot taken in my garden last spring of St. Brigid anemones grown from our own seed. They are the most glorious colour and size I have ever seen. It would be interesting to find out whether any other readers of THE GARDEN have had such fine results.—D. BUCKNALL, *Co. Cork.*

Digitized by Google

NOTES FROM CONTRIBUTORS

PODDED PEAS IN POTS.

THERE is no doubt the growing of certain vegetable crops under glass is educative and interesting work, and in these days many people might make more use of empty glass structures by growing culinary peas. The variety Sutton's Little Marvel may not be the best for indoor culture, but certainly this kind is most suitable for pot work, and especially for those having little spare room under glass but who nevertheless wish to have pea pods for picking in April and May.

Some time in the first or second week of November is a good time to have the peas sown. Our practice is to crock a number of clean 4in. pots and to fill these to about 1in. from the rim with a medium fine soil consisting of fresh loam with which has been incorporated a little sand and old lime. Seven or eight peas are set in each pot and covered with ½in. of soil. This may seem a large number of seeds for a 4in. pot, but we have got to allow for a few plants in the batch damping off or getting damaged; then an 8in. or 9in. pot is not really well furnished with fewer than six or seven plants.

After germination and when the young plants are about 1in. high, place the pots on a shelf near the roof glass in an airy structure, but where safety from frost is assured. Careful watering throughout the dark days of winter should be made a rule; indeed, the watering of peas at all times should be most carefully done. About the middle of January preparations should be made to have the plants accommodated into 8in. and 9in. pots. The 4in. pots, although containing six, seven or eight plants each, should be repotted as one plant. A soil mixture of equal parts fresh loam and leaf-mould, with a little sand, old lime and wood ashes, should be used. The soil should be only moderately firmed in the pots; but one special point to bear in mind while the work of repotting is going on is to keep the old ball, *e.g.*, the mass of earth and roots taken out of each 4in. pot, slightly raised above the level of the fresh potting material surrounding it in the larger pot.

The staking of the plants should be done as soon as the stems have made sufficient growth, but certainly before they get bent over. By the middle of March the plants should have grown 12ins. high and be in flower; in fact, some may be more forward than others and even have tender pods 1in. long. If one looks carefully at these pods the small embryo peas—up to six in number—can be seen through the tender skin of the tiny pod.

Each individual plant will bear several flowers, but Little Marvel does not seem to produce more than one bloom per pedicel. The plants after being repotted were set on a strong shelf in the late peach house. Here good light and plenty of air were afforded, and here the plants produced their podded crop.—DAVID ARMSTRONG, *Midlothian.*

NANDINA DOMESTICA.

THERE seems to be a ready sale at Covent Garden market for sprays of this evergreen and at the beginning of the year the consignments from the South of France included a goodly proportion of berried branches which were eagerly snapped up by the West End florists. The erect racemes of bright red berries, which are a trifle smaller than those of the Fire Thorn, add materially to the decorative value of the shrub. Although it flowers freely in the warmer parts of the country I do not remember having seen any fruits on home-grown plants, though probably they have been produced occasionally during favourable seasons. Nandina domestica is an evergreen shrub for the more favoured parts than for general planting, though it would thrive as a wall shrub in many districts. The best and most vigorous plants are obtained from seed, but germination is not usually good in this country, so most of the stocks are raised in Japan and imported. Cuttings placed in a mild heat will root, but it is usually a slow process.—A. C. B.

THE MIMULUS AS A BORDER FLOWER.

AMONG the bright garden plants which are much too seldom grown are the many fine varieties of the mimulus or monkey flower. They are, perhaps, not of highest value for cut blossom, but in the border they certainly make a handsome show. Nothing particular need be said about their culture; sown in heat, transplanted when small and finally hardened off in the frame, they are ready for bedding in May. They flower almost as soon as they are put out and continue to increase and flower till frost stops them. I would point out that the mimulus revels in a damp soil and seldom does well in a sunny dry site. We have had them particularly fine these last two wet summers. The Rosy Morn varieties are easily best; they grow compactly and have beautiful salmon-rose flowers of large size. The Tiger varieties are blotched in a peculiar but pleasing and striking fashion. Then, of course, there are others to meet all tastes as regards colour.

Musk belongs to this genus; we grow it as an annual and as a perennial, but we would be grateful to any reader who could tell us where to get seed of the old sweet-scented perennial which we lost during the war.—LANARKSHIRE.

SCHIZOSTYLIS COCCINEA.

DURING the month of October, this plant made a fine splash of colour in the flower garden, producing a wealth of its spikes of crimson-scarlet blooms. It is a plant worth growing in quantity for cutting purposes, while it is also well adapted for pot culture, the flowers being protected from bad weather in a cool greenhouse come to full perfection. Known as the Crimson Flag and Kaffir Lily, it hails from South Africa, and is a bulbous plant of merit. It will succeed in any average garden soil, preferably a sandy loam, so heavy soils could be made suitable by the addition of leaf-mould and sand. In the front of a shrubbery border, a warm, sunny spot on the rock garden, and in cold districts at the base of a wall facing south, are ideal places for this delightful plant. In a few years the roots will become crowded, and then it will be necessary to lift and divide them. Such work is best carried out in the spring, and when dividing each piece should consist of five or six shoots. Replace 9ins. apart, and if placed in the same spot, enrich the soil with a dressing of partly decayed manure. A variety named Mrs. Hegarty has rose pink flowers.—T. W. B.

CROCUS SIEBERII.

SOON after the New Year has begun, in a mild winter with some sunshine, which we do not have too frequently, we eagerly look for the appearance of the dainty little Crocus Sieberii, which has been characterised as "a hardy mountaineer, anticipating all others." It is not really so precocious, but it is one of the best of the very early crocuses, standing rough weather better than some by reason of its greater substance and moderate size. Were it as large as the modern Dutch crocuses it would have a poor chance of surviving the trials of January and February. As it is, it is all the better for a sheet of glass above it to throw off snow, sleet and heavy rain, but it does not require this if we are disposed to run the risk of its beauty being prematurely destroyed by an unusual trial of endurance. It is very charming to see a clump or mass in a sunny border, on rockwork, or in grass, opening to the scant sun of January or February. Its beauty is great indeed, though of comparatively miniature type. The flowers are a bright lilac with a yellow base and an orange yellow throat and are remarkably pretty, either closed or open. There is a very rare and expensive variety, almost unprocurable, called versicolor, of varying colouring but delightful in every way. C. Sieberii itself is not expensive and may be procured in early autumn and planted about 2ins. deep in light soil in a sunny position. The planting should be done as early in autumn as possible.—S. A.

ANEMONE PALMATA.

ONE is accustomed to the most surprising variation in the anemone family as different species come to be known, but those who have not met this—which is sometimes called the cyclamen-leaved anemone—should be prepared for a very remarkable and most showy plant. It does not flower until early summer, but is then a gorgeous picture indeed with its masses of golden yellow glossy blossoms. These only open in full sunshine, a hint that should be taken when planting to give it a very sunny position. This is still more important in view of the native countries from which this plant originally came to us—Spain, North Africa, etc.

The leaves are heart-shaped, somewhat hairy and slightly toothed on the margin. The roots are tuberous and may be planted at any time during the dormant season, a specially successfully spot being in the rock garden, where a pocket can be filled with a mixture of peat and turfy loam to which some leaf mould has been added. Do not omit the peat or leaf-mould, for these are invaluable aids in retaining moisture which is one of the chief demands that the plant will make during summer. Further plants may be obtained by the alternative methods of division or raising from seeds.—SANDSTONE.

SEED SOWING IN THE ROCK GARDEN.

NOT infrequently in the construction of a rock garden, the furnishing is proceeded with almost immediately by procuring the necessary plants. It is looked upon as quite incomplete unless the niches and spaces are covered. The question of cost however, sometimes precludes the whole of the space being utilised and, as spring approaches, the question arises as to what is best to be done. Strange as it may seem, I have met friends who, while raising annuals and perennials from seed in a general way, cherish the idea that so far as the furnishing of a rock garden is concerned, raising plants from seed therein is a long and often drawn-out process. It is only part of the truth, as there are many things which emblazon our rock gardens in spring that may be sown in a cold frame in April, pricked out and planted when the time arrives, becoming large enough to occupy their places among the stones and rock the following spring. Such are some of the campanulas, aubrietias, dianthuses and saponarias. In too many instances it is an eagerness to have a fully furnished rock garden filled with flowering plants at the earliest possible date that accounts for the comparative few who raise plants from seed.—CLAREMONT.

OBITUARY

MR. WILLIAM WATSON,

A.L.S., V.M.H.

IT is with sincere regret and a sense of a deep loss to horticulture, that we record the death of Mr. William Watson in his sixty-seventh year. The Curators of Kew have rarely lived long to enjoy what should be a well earned rest on their retirement and Mr. Watson has had a more brief period than his predecessors, for it seems but yesterday that he retired from the Curatorship. For some months past he had suffered from heart trouble and lately entered a nursing home at St. Albans in the hope of renewed health, but died on January 30th and was buried in that old city on February 2nd.

Mr. Watson was in the Royal Botanic Gardens, Kew, for nearly forty-five years, and during the greater part of that time "Watson of Kew" was known wherever plants are cultivated and, beyond, even in the wilds of the tropics. He came to Kew in July, 1879, as a cultivator—to be exact as an expert propagator—and throughout his career was a cultivator first and foremost. He possessed an exceedingly wide knowledge of plants of many kinds and their cultural needs, and, added to this, had a most enviable gift of writing about them in such a manner that, to the plant lover, the plants of which he was writing lived in his written descriptions.

It is always the busy man who finds time to do things, and besides his official duties during his long period as Assistant Curator to the late Mr. George Nicholson and later Curator in succession to him, Mr. Watson found time, or rather made time by burning liberal quantities of the midnight oil, for writings. He contributed generously to the pages of THE GARDEN and other important horticultural journals; for a considerable time he was Garden Editor of *The Field*, and the literature of horticulture is enriched by a number of books from his facile pen. His most important works are the Editorship of "Thompson's Gardeners' Assistant," which from a single volume he made into an extensive and authoritative work. He wrote the volumes on rhododendrons and azaleas and on climbing plants in the Present Day Gardening Series, while his books on orchids and cacti are still unequalled.

As we have said, Mr. Watson was at heart a cultivator beyond all his accomplishments, and the families of plants he made particularly his own were orchids, cacti and rhododendrons. Of these he possessed an amazing knowledge, although it was difficult to mention a cultivated stove or greenhouse plant which he did not know.

But great as was Mr. Watson's skill and learning he was essentially a "human man" and made many friends, whether they were met in his official capacity, on his visits to famous gardens, at the great Ghent and other Continental shows or during his long-ago voyage to South Africa. He had the welfare of his fellow men at heart and this compelled him to take a leading part in the formation of the Kew Guild and the British Gardeners' Association. For many years, more particularly while he was Assistant Curator, he was chairman of the Mutual Improvement Association of the Royal Gardens, when he would draw, often with kindly humour, from his great fund of knowledge to the immense benefit of the students, and, during his younger days, he took an active part in the sports clubs connected with the Gardens.

In 1916 Mr. Watson was awarded the Victoria Medal of Honour, but he valued most the degree of Associate of the Linnean Society which was conferred on him earlier in appreciation of his long services to the world's horticulture.

He was twice married and leaves a widow and large families. His eldest son, Mr. J. G. Watson, who was trained at Kew, is Conservator of Forests at Jahore, Federated Malay States. To his widow and families we tender our deep sympathy in their loss. A. C. B.

CATALOGUES RECEIVED.

Messrs. James and George H. Matthews, Catalogue of Garden Seeds for 1925. One or two features of interest are the lists of Scotch seed potatoes and their high grade horticultural fertiliser. We would also draw attention to the special mixture of lawn grass seeds, which will provide a really first-class lawn on any ordinary soil. It may be mentioned that this firm has a licensed seed testing station and that consequently their seeds are of a high standard over and above that required by the government.

All potato growers realise how necessary it is to obtain the best of seed so as to ensure a good crop, and of late years, with this end in view, Scotch seed potatoes have come to the very forefront. Our readers perhaps know that certain districts and areas in Scotland produce exceedingly fine seed potatoes. The district around Dunbar is one of those. This season has been a difficult and trying one for all growers, especially of potatoes, and it is predicted that there will be a considerable shortage of seed, and so we advise our readers to order early. We have great pleasure in bringing before all potato growers the name of Mr. Charles J. Spence, Potato Grower, Dunbar, whose catalogue we have before us. It deals solely with potatoes, as Mr. Spence's attention is concentrated on this particular line, so that the important questions of selecting and grading receive great care. Useful hints on the general cultivation of potatoes are given in the catalogue, which will be of great service to all raisers of this valuable and economic crop.

We are pleased to bring to the notice of our readers the excellent catalogue of garden seeds for 1925 presented by Messrs. Toogood and Sons, Limited, Southampton. It is a fairly copious manual, running to 160 pages and profusely illustrated. The space is divided almost equally between vegetable and flower seeds, with a small section on garden requisites which is most complete. The intending buyer is confronted with a wide variety from which to make his selection, and although the quantity appears extensive, the quality will not in any way have been interfered with. In fact, it may be safely said that Messrs. Toogood have done much to improve the quality of all their strains during the last year, while at the same time maintaining a high cropping capacity. All seeds are guaranteed, and we feel certain that satisfaction will result from a perusal of this catalogue on the offchance that something may appeal to the reader's fancy which might at some future date adorn his garden.

In the West Coast of Scotland there is one firm with a widely known reputation among the gardening public, and that is Messrs. Austin and McAslan of Glasgow, whose 1925 Catalogue of Vegetable and Flower Seeds has just come to hand. For more than 200 years Messrs. Austin and McAslan have served the horticultural public, and their success is in no small way due to the high standard of excellence which they have maintained through all these years in all branches of their business. In the world of vegetables they have made a name, especially with potatoes, great care having been paid to selection of good seed, and we feel sure that seed despatched will give first-rate crops. Many pages are devoted to flower seeds, while a section deals with implements and garden requisites. It is a comprehensive guide for 1925, running to seventy pages and contains numerous illustrations. We have pleasure in bringing it to the notice of all readers in Scotland.

Messrs. Richard Melhuish, Limited, Hardware Merchants, 50–57, Fetter Lane, E.C.4.: Gardening Tools and Sundries, with numerous line illustrations. This catalogue will be sent post free on application to any of our readers who apply to the above firm.

D. G. Purdie, 6, Waterloo Street, Glasgow. Vegetable and flower seeds are chiefly dealt with, in addition to a section on sundries. A few half-tone reproductions occur throughout the pages, while brief cultural hints are given which should be useful to amateurs. The catalogue will be sent free on application.

Messrs. Kay and Co., Goodmayes, Essex. A useful flower seed catalogue with a small supplement dealing with vegetable seeds. Profusely illustrated by means of half-tone reproductions.

One of the names generally associated with shrubs is that of Messrs. Robert Veitch and Son, Exeter, but their reputation as seed merchants is also of high standard and their list of seeds for 1925 is well worth perusal. It is a comprehensive guide of vegetable and flower seeds, with a section devoted to tools, manures and insecticides and general sundries.

Other seed catalogues which have been received are those of Messrs. Harrison and Sons, Leicester, and Messrs. Dixon, Hull. The catalogue of the Gateshead seed establishment will be found useful for reference purposes. It is well printed and the half-tone illustrations are excellent. Much interesting matter will be found in its pages.

Another Scottish catalogue for 1925 which we take the liberty of bringing before our readers is that of Messrs. Laing and Mather, The Royal Seed Establishment, Kelso. Messrs. Laing and Mather devote the whole of their time and attention to seed, and they fulfil the old adage about "doing one thing and doing it well." A new departure is to be seen in their catalogue—short cultural notes written by prominent head-gardeners in Scotland on the different vegetables being given. These notes and useful hints should prove both popular and instructive to all amateurs. The greater part of the catalogue is devoted to flower and vegetable seeds, while a few pages deal with garden sundries and requisites. We offer our congratulations to Messrs. Laing and Mather on this season's publication. It is well worthy of the attention of all amateurs and professionals.

The majority of amateur and professional gardeners clearly recognise the value of all garden sundries. It is astonishing how all these little things find a daily use and prove of real service to the gardener in the carrying out of his duties. In this connection we are pleased to bring to the notice of our readers the catalogue of Messrs. Joseph Bentley, Limited, Hull. The gardener will find this an extremely handy reference guide, containing as it does, numerous illustrations and copious notes on all specialities and sundries which go to make work in the garden a pleasure instead of a task. It is one of the most comprehensive guides on garden sundries we have seen, and we can recommend it to our readers.

Messrs. J. R. Pearson and Sons, Limited, Lowdham, Notts, are probably known more in connection with bulbs than any other branch of gardening, but we are reminded that they deal in the general routine work also by their Vegetable and Flower Seed Catalogue for 1925, which has come to hand. The catalogue is of a handy size, well printed and contains numerous illustrations.

Messrs. Godfrey and Son, Exmouth, Devon.—A Concise List of Chrysanthemums; Novelties for 1925.

Messrs. Barr and Sons, 11, King Street, Covent Garden, W.C. Catalogue of Bulbs and Tubers, containing a representative

FERTILISERS

IN this issue begins a short series of articles on manures. These explain various kinds and how each enriches the soil in some specific manner. Manures from an æsthetic point of view are considered unclean: the word brings to mind a mental picture of a cow-byre or a pig-sty and their contents; in fact, it is a misnomer and should be banished from the vocabulary. This, however, is easier said than done, as its long usage has established its position in this connection. Fertiliser is a much pleasanter word and does not carry with it the suggestion of a dank rotting smell.

And yet how important is this enrichment of the soil. It is a new science which is only slowly within the last few years becoming understood. It is the foundation of all good agriculture and horticulture. When one reads these articles one gets some slight idea of what voracious appetites plants have and what a curious bill of fare suits their tastes. Rotten fish, farmyard manure, bones, ashes, by-products of gasworks, potash, dead leaves and garden rakings, wood ashes, basic slag, phosphates, and hundreds of others all have their uses.

The point of these articles is to show the uses of the various groups of fertilisers and how different soils and plants require different treatment. Not so many years ago farm manure and refuse from town dustcarts alone were used for feeding the soil. Now the old order has changed and scientists are showing us how to enrich our land both scientifically and economically.

A POINT IN NOMENCLATURE

A trade correspondent has written to us regarding the suffix i or ii in the termination of names of plants. He says that he has personally asked many nurserymen, but that they have always avoided the subject. He gives several examples, *i.e.*, Newmanni, Lowii, Veitchii, Henryi, Ingrami. Before answering I have taken the precaution of asking the advice of several classical scholars. They all say that there is no rule about the use of i or ii, and that it is merely a question of euphony. It is impossible to explain why Lowii sounds better than Lowi, but it does, and in the same way Ingramii is horrible compared with Ingrami. One of my informants tells me that even Henryi is untenable, for Latin never used y except in words borrowed from the Greek to represent the Greek u. He says: "If Henryi is for Henry, surely they might use Henricus, and in genetive Henrici." This, of course, opens out the field into a far larger sphere, namely, the correct change of modern names into a classical tongue for the purpose of plant nomenclature. There is little doubt that this is often done, sometimes carelessly, by people with little classical education. I remember Reginald Farrer complaining bitterly about the use of a Latin specific name tacked on to a Greek generic name or *vice versa*, *i.e.*, Rhododendron glabriflorum or Primula euosma.

THE SAME OLD QUESTION

In our issue of February 7th there was an article by Mr. Harley on meconopsis, which has obviously caused a great deal of interest among our readers. The number of letters received has been extraordinary. In almost all of them the writers have asked where seeds could be obtained. I have had to reply that with possibly one exception they are unobtainable commercially.

Now here is an occasion where I can justifiably complain that that portion of the trade who specialise in alpines have been short sighted and negligent. This is not a case of new importations, for M. Wallichii and M. simplicifolia have been known since before 1850; M. integrifolia and M. quintuplinervia before 1885; M. grandis and M. paniculata before 1900. They have for long been grown by enthusiasts throughout the country, not only in one garden; I personally know of at least a dozen where meconopsis of one kind or another have been grown for a number of years. With the exception of M. grandis they are all free seeders. They are easy to germinate and also easy to cultivate once the trick has been learned. And yet with all these advantages the trade who specialise in rock plants have made no effort to stock or push these fascinating plants. The public is also to blame, for they have had opportunities for seeing them, not only in private gardens, but also at Kew, and particularly at the Edinburgh and Glasnevin Botanic Gardens. When their attention is drawn to them in print they become enthusiastic, but not until then. Still, better late than never, and it is to be hoped that the sudden demand for meconopsis will create a supply.

E. H. M. C.

AMONG OTHER ARTICLES IN OUR NEXT ISSUE WILL BE:

THE GARDENS AT RIDEAU HALL, OTTAWA, by George Simpson.

THE CONSTRUCTION OF A LAWN TENNIS COURT, by Reginald Beale.

GARDEN PEAS, by Edwin Beckett.

BOTANICAL BOOKS.

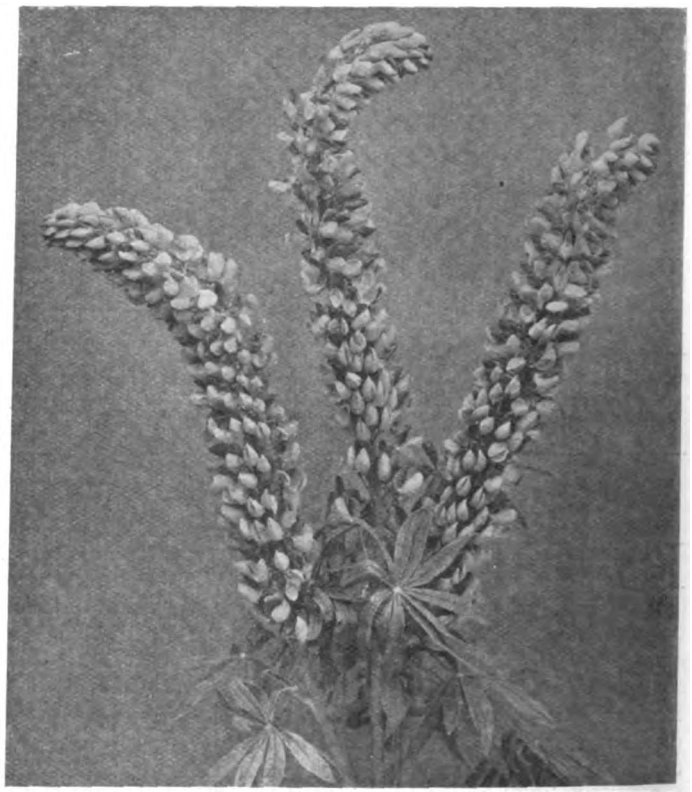
MODERN LUPINS

LUPINS, FOR LONG THE CINDERELLA OF OUR GARDENS, HAVE MADE A GREAT BID FOR OUR APPRECIATION WITHIN THE PAST FEW YEARS

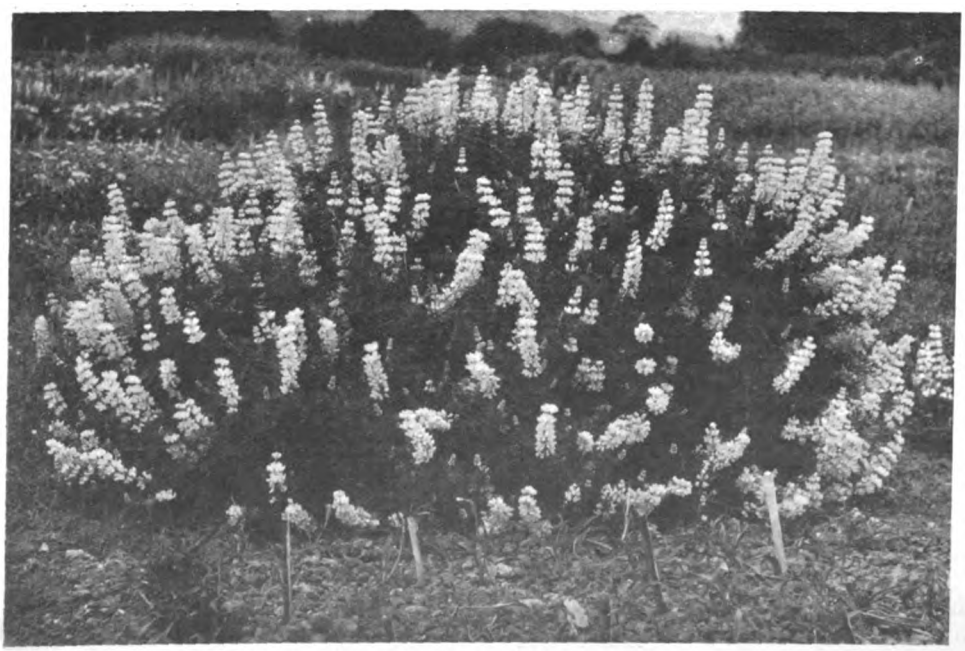
GRATIFYING indeed has been the wonderful advancement of Lupinus polyphyllus, a plant which, having grown for a century or two among the commonest of garden flowers with apparently no particular ambitions or great aspirations to popularity, has of recent years been so wondrously transformed that it serenely takes its place among leading families of hardy perennials and carries a list of named varieties comparable in length with phlox, pyrethrum, and pentstemon, and almost with the kingly delphinium. There is a certain element of mystery in this rapid evolution, and a good deal of hazarding guesswork as to whence has come the kaleidoscopic range of entrancing and indescribable shades and combinations of colour. Time was when one might sow a thousand seeds of Lupinus polyphyllus, knowing that, apart from the inevitable few albinos, by no means remarkably pure in their whiteness, the bulk would fluctuate but slightly between lighter and darker shades of blue. To-day there is apparently scarcely a limit to the variation of tints procurable from a batch of seedlings of one of the best strains, and the lupin has all but proved to be the notable exception to the rule that all the primary colours cannot be maintained in a single floral subject. That hybridisation has had a hand in the process of evolution may be considered beyond dispute, and that some, at any rate, have been the outcome of amalgamation between L. polyphyllus and L. arboreus (the tree lupin) is not difficult to prove. It is a moot point whether that union was not somewhat of an indiscretion; at any rate, some producers are particularly careful to impress upon the world that their strains are not contaminated with arboreus blood. The important point is that L. polyphyllus is a true herbaceous plant, the stems soft and hollow, dying right back to the root stock, next season's growth proceeding from a number of fleshy buds close-set upon the crown of the roots. L. arboreus, on the other hand, is woody, branching, and solid or pithy in stem, new growth issuing from stem joints at the axils of the previous season's foliage. The hybrids not only produced shorter spikes of bloom than the true polyphyllus, but adopted something of the pithy stem and branching habit at the expense of the crown-eyes, and being softer than the wood of L. arboreus these branches frequently succumb to winter's frosts.

That the coveted yellow colour has been produced by arboreus crossings is readily admitted; but when, as has sometimes been asserted, the theory is put forward that L. arboreus is necessarily a parent of all yellow lupins, one is disposed to query its accuracy. It must not be overlooked that there are other herbaceous species of lupin besides L. polyphyllus, and two have some yellow in their colour scheme, albeit in a subordinate degree. Subordinate characters sometimes become predominant in hybrids, and instead of hastily concluding that L. arboreus influence must be accepted and tolerated in the highly desirable yellow hybrids, let the comforting thought be pondered that we may have L. Cruickshankii and L. nootkatensis to thank to some extent. There are, as a plain matter of fact, quite a number of distinct strains of lupins in cultivation, and for my part I should not only hesitate to assert that this particular strain or that excels all others, but would not readily bow to such opinion even though expressed by great authorities. I prefer the theory that the various strains are the outcome of work on distinctly different lines, and that while one strain is strikingly superior in certain features, another is also to be prized because of its excellence in quite other directions.

The "Regal" strain, I will readily admit, strongly appeals to me because it embraces wonderful suffusions of apricot, orange, buff, amber and terra cotta—colours I am fond of in any flower, and raise my hat to in lupins because they mark such a triumph in a family that erstwhile knew nothing approaching such tints. At the same time, an impartial judge will probably proclaim Downer's Delight to be the finest individual break in all the lupins. It is a very remarkable flower, and in its really true form touches a colour that renders criticism unjustifiable.



ONE OF THE FINEST OF ALL LUPINS, DOWNER'S DELIGHT.



THE TREE LUPIN, LUPINUS ARBOREUS WITH ITS CHARACTERISTIC BRANCHING HABIT.

Digitized by Google

I say "in its really true form" because one occasionally drops across seedlings which, although quite good and worthy of use for ordinary garden adornment, are not equal to close comparison with propagated plants of the true stock.

Lupins, being leguminous, are capable of fairly reliable self-fertilisation, and seedlings from an isolated batch come wonderfully near the true thing. Thus, for the herbaceous border, seedlings in selected colours are highly to be commended, and like most plants, those raised by Nature's method of increase are frequently stronger and more vigorous than those from successive generations of cutting-struck plants. Nevertheless, when plants are ordered to name for the purpose of growing for show, it is very important that the real thing shall be secured.

One is safe with Harkness for Joy, a wonderful apricot-pink with yellow wings. It is dwarf as lupins go, but a very free and fascinating flower. Gold Crest is in two shades of sharply defined markings of fiery crimson. In this strain there seems to run a decided family likeness which carries conviction that Lupinus nootkatensis is a parent.

Newcomers deserve a note of commendation and encouragement, and Mr. H. Marcham, Borough Green, Kent, showed during last summer a very fine range of hybrid seedlings which embraced all manner of quaint, dainty and very pretty art shades. Mr. Marcham's aim is not to pick out varieties for naming but to maintain a strain which, planted *en masse*, will produce a veritable riot of colour, all the shades contributing harmoniously to a sumptuous feast of beauty. Messrs. G. Bunyard and Co., Maidstone, were among the early pioneers of lupin development, and both they and Messrs. Cheal and Sons, Crawley, have been very careful to purify and improve the pink variety of L. polyphyllus.

Messrs. Laxton Brothers, who studied fragrance and developed that valuable quality in their pleasing race of hybrids,

LUPINS IN ALL SHADES OF COLOUR ADORNING AN EARLY SUMMER BORDER.

yellow, a real beauty; Tangiers, apricot and yellow; and May Robinson, apricot and fawn. The "Regal" strain is by no means confined to these shades, although they are an outstanding feature. Firefly, for instance, is very bright—rosy scarlet being an apt description of its shade. Mrs. Jack Pearson is lavender with opalescent shading of rose; and Mary Harrison is blue with the glistening sheen of highly tempered steel. Rosea bicolor is rich pink and white. Downer's Delight, already referred to, is a rich ruby red, but this strain excels in shell pinks, rose shades, salmons and again in Cambridge blues, lavenders and lustrous purples. May Princess is specially fine in the last-named colour, and Downer's Pink Pearl is extremely fine in rose pink. Length of spike is a noteworthy feature in the whole strain, but Highlander (rose), Mount Everest (white) and The Forge (mauve) are among the longest spikes.

George Gibson of Leeming Bar has quite a number of varieties in what may be termed rosy lavender and mauve shades, while his Ruby King is an intensely dark purple with doubtless found L. arboreus a very useful breeder for their purpose, and although its tendency is to shorten spikes it compensates by greatly increasing their numbers. In southern gardens the arboreus hybrids survive winters if afforded some shelter from wind, as by a hedge or wall, while many worse plants than these are accommodated in unheated greenhouses.

Mr. T. Carlisle's Light of Loddon is unbeatable as a rich yellow lupin, and its season of flowering extends over a very long period, well into autumn.

Lighter in shade, but still beautiful, is Waterer's Sunshine, a plant that has sold in extraordinary numbers. Messrs. Waterer, Sons and Crisp have recently introduced another, and one of the sweetest and most elegant of all lupins. Dresden China is its name, particularly appropriate, for its delicate type of beauty almost compels one to handle it as though it were a fragile china flower.

The tree lupins themselves have been the subject of not a little attention. The ordinary yellow type and the white

Digitized by Google

form were both improved by selection years ago in the Ditton Nurseries of Messrs. Barr and Sons, now of Taplow; but since the advent of Snow Queen a great advancement has been made in these extremely useful shrubs of conveniently moderate dimensions. T. Smith, Daisy Hill Nurseries, Newry, Ireland, did capital work upon this as upon many other good old plants. Quite a series of bewitchingly beautiful bi-coloured varieties emanated from this famous nursery, and whether one's tastes lie in the direction of soft mauves, lavenders and violets in combination with white, or toward brighter tones such as yellow and purple, cream and blue, orange and yellow, the Daisy Hill tribe is equal to requirements. L. I. ATRIS.

THE UPKEEP OF A LAWN

BY REGINALD BEALE.

WEEDS must, of course, come first, for the reason that they start giving trouble from the word "go" and never cease to vex. There are many sorts of weeds, and in order to eliminate them with the least amount of trouble and expense, it is necessary to divide them into classes and deal with them accordingly. In a new lawn many weeds must be expected, and they have got to come out if a good lawn is required, and the sooner they are taken in hand the easier it will be to eradicate them. The best method to adopt is to place a plank along the edge of the lawn, and while standing on it remove all the weeds and coarse grasses within reach, then step off the plank, turn it over and proceed as before. If the weeds are taken in hand when they are young and before they have had time to root deeply, they will come out quite easily, often by just pulling them, without the use of a tool, and little or no damage will be done to the surface.

Weeding old turf is an entirely different proposition; daisies and other surface-rooting weeds can be quite easily destroyed by the application of "Carterite," either in the autumn or early spring. The work should be taken in hand during still bright and fairly dry weather. Give each worker a distributor, which is a conical tin having a lid at the large end, at which it is filled, the smaller end having an opening ⅛in. in diameter, and instruct them to proceed as follows: Place the first finger of the right hand over the opening and fill the tin with the powder, which is allowed to escape from the tin by removing the finger for such an interval as may be necessary to allow, say, a saltspoonful to fall on a small plant, and so on. The quantity required for a given area depends upon the number of weeds on the turf, but on the average it works out at about 2 oz. to 4 oz. to the square yard. Large patches of daisies, self-heal, chickweed, clover, etc., should be removed bodily and replaced with clean turf or dusted heavily with "Carterite." If the latter method is adopted, bruise the clumps with the foot before the application, and renovate the bare places caused by the destruction of the weed, with grass seeds, a week or ten days later.

Plantains and other weeds of a similar habit are too strong for the above treatment and too small to poison, the only alternative being to remove them bodily with a three-pronged fork. The holes should be filled up with sifted compost and seed in the ratio of about a pailful of the former to a pound of the latter. If any deep holes are made by the removal of large weeds or tufts of grass, tamp the filling in with the handle of the fork until it is quite firm, otherwise it will settle and form cuppy depressions.

Dandelions and other weeds with long tap roots can be destroyed easily and rapidly without any back-aching labour by the use of Smith's Arsenical weedkiller, ejected on the crown of the weeds by the use of a weedkiller ejector. Prepare the weedkiller at double the strength recommended by the manufacturers, fill the ejector and screw in the plug. Search out the weeds—they are easily seen, particularly in the spring—and squirt a little of the weedkiller on each, regulating the quantity to the size of the weed. Two or three days later the foliage begins to wither and within a week the whole weed is dead from end to end. It is hardly necessary to point out that the poison should be kept under lock and key, and the hands and all implements should be washed immediately after use.

Coarse grasses may be cut out and replaced with good turf or grubbed out with a fork, or, if there are too many to be treated in this way, weaken them as much as possible by close cutting and slashing the hard tufty plants across and across the crown with a knife. In hopeless cases, where weeds are in such numbers as to defy ordinary measures, dress the whole area with "Carterite" by means of a dredger, at the rate of 4 oz. to 8 oz. to the square yard. The "Carterite" will scorch and burn everything, the turf included, but as a general rule the grass quickly recovers, while anything from 75 per cent. and upwards of the weeds are killed and the remainder can be dealt with individually later.

Clover is perhaps one of the most difficult weeds to deal with; it grows everywhere and on all classes of soils. When the plants first show themselves they can be easily removed by hand; but if they are allowed to spread and form large dense clumps—and they will very quickly, particularly if bones or other phosphatic fertilisers are used—it is very difficult to master. It can be discouraged by repeatedly dressing the turf with Carter's Anti-Clover Grass Fertiliser on the "little and often" principle, at the rate of from ½oz. to 1 oz. to the square yard, mixing the fertiliser with sufficient sand or sifted soil to increase its bulk to such an extent as to make its even application possible, allowing an interval of two or three weeks between each dressing, which should be watered in if necessary. Clover can be weakened to the point of extinction by cutting it as close as possible when the weather is hot and bright with a sharp scythe or horse clippers, or by tearing it up with a rake and cross mowing with the machine set low. It can be burnt out by dressing the patches with "Carterite" at the rate of 2 oz. to 4 oz. to the square yard, or they can be cut out and repaired with good turf.

Small plants can be removed by loosening the soil and following up the runners with a two-pronged steel dinner fork. This is very much like plucking a hare, but it can be and is done.

In all cases weed systematically and try out a system in order to obtain experience before committing oneself too deeply.

Worms are the most troublesome pests that attack turf; they riddle the soil and turf to such an extent that it becomes unnaturally muddy and soft, which cannot be corrected by rolling, and otherwise strong turf is made so tender that it soon wears out. They cover the surface with their evil-smelling slimy casts, which not only foul the turf, but when trodden and rolled down actually smother out the fine grasses, and the damage they do to the mowing machines is beyond belief. They work hardest in heavy soils, and although there is no apparent connection between worms and weeds, they are closely allied, as the slimy casts make wonderful seed beds for weeds and they are always found together, particularly in damp hollows. The more one studies the subject the more apparent it becomes that where they abound the turf is always coarse, weedy, muddy and soft under foot, and where they are conspicuous by their absence it is finer in quality, freer from weeds and cleaner and firmer underfoot. The worms can quite easily be destroyed by scattering Carter's Wormkiller over the surface at the rate of half a pound to the square yard, on a warm, dull, misty, muggy day, and watering it in with a hose, water-cart or cans. I am conscious that many keen gardeners are opposed to the destruction of worms in turf, but if they were to make a trial on a few square yards it would prove both interesting and instructive. The wormkiller is not poisonous to either animal or bird life; it will only kill worms and fish, and in consequence can be used with safety.

Assuming that the worms have been destroyed, soft muddy lawns can be made quite firm by top-dressing them with sharp sand, sifted cinders, breeze or charcoal, fine enough to pass through a ¼in. square mesh sieve. It is verging on the impossible to keep a grass path or lawn in good order if used in the winter, on anything approaching heavy soil, without destroying the worms and dressing it with one of the above-mentioned materials.

Fertilising is very important; and there are many lawns that look starved. If they were fed with Carter's Complete Grass

Digitized by Google

Fertiliser, at the rate of 2 oz. to the square yard or 5cwt. to the acre, their expression would change, from haunting starvation to satisfied contentment. The fertiliser should be mixed with about three times its own bulk of sharp sand for heavy soils, and loam compost or the remains of an old hot-bed for light hungry soils, passing the whole through a fine mesh sieve before use in order to complete the mixture and exclude any small stones and other rubbish which might damage the lawn-mower.

Rolling and mowing are rather difficult subjects for discussion without taking up more space than has been allotted. These subjects have been dealt with in my book, "Lawns for Sports," so perhaps I may be excused for these short notes. All lawns should be rolled periodically during the autumn, winter and spring, choosing days when the ground is neither too wet nor too dry. For general garden use there is nothing to beat The Alexandra Double Cylinder Roller, manufactured by Messrs. Barford and Perkins in varying sizes from 14ins. in diameter and width to 24ins., at prices ranging from £2 15s. to £6 10s. There are all sorts of other rollers in wood and iron, one, the "Sarel" patent spike roller, 3ft. wide, price £6 7s. 6d., being particularly valuable for use before and after using fertilisers, top-dressings, etc., and also on soils that are inclined to pack and become stagnant.

Of mowing machines there are multitudes. Among small hand-machines, Ransome's "Marquis," and Shanks' "Caledonia" represent the cream on the market; while the "Dennis," the "Godiva" and motor mowers manufactured by Ransome's and Shanks' give a choice sufficient to satisfy the most fastidious. There are many, however, who possess good machines of various makes which are uneconomical because they are beyond the power of one man, and yet one hesitates to scrap them and purchase a motor mower. The "Rendle" motor mower and roller attachment solves this problem most satisfactorily. This power unit can be attached to any make of roller machine with a cut from 16ins. to 30ins. or any type of roller up to 20cwt.; in fact, a handy man can adapt it to push anything, within limits, that is pushable. Many think that these attachments are makeshifts, and so they are in a sense, but when it is realised that in combination with a first-class mowing machine they give a polished finish which no motor mower will give, with a minimum of physical effort, they are well worth consideration. The cost of installing an attachment or a motor mower is fairly heavy, but there is no doubt as to their economy. My good friend and head-gardener, Mr. Walter Cole, who is as keen as he is efficient, which is saying a good deal, has proved that he can get through the mowing at a saving of at least one-third in time, and that the operator at the end of the day is fresh instead of being, as he calls it, whacked to the world. The reason, of course, is simple; anyone can walk behind a machine, guide it and go at a greater pace, with less fatigue, than if one has to use all one's strength in pushing it along.

Before taking in hand the renovation of a lawn, mow the grass as close as possible and then test the soil for lime, and if it is deficient, apply a dressing in the form of carbonate of lime at the rate of 1lb. to the square yard or 2 tons to the acre. Granted that the correct season to apply lime is the late autumn or early winter, it can, however, be used at any time without loss provided that there is likely to be sufficient rain to wash it in and fertilisers are not applied until it has been washed in. The lawn should then be dressed with Carter's Complete Grass Fertiliser or, if clover is troublesome, use an Anti-Clover Grass Fertiliser at the rate of 2 oz. to the square yard or 5cwt. per acre, mixed with two or three times its own bulk of sifted compost, soil or sand in order to increase the bulk and so make an even application possible. Then rake the surface with care and judgment, with the object of working in the fertiliser, tearing out the dead herbage and moss and finally opening up the soil and so forming a seed-bed. Sow the raked area with a mixture of grass seeds carefully selected to suit the soil and match the existing turf at the rate of from ½oz. to 1 oz. to the square yard, according to the condition of the turf, sowing the seed thickly where the turf is dead or thin, and thinly where it is fair to good. If in doubt as to whether a mixture with or without rye grass should be used, send a small but representative sample of the turf with your order and leave the rest to your seed merchant. Rake the seed in carefully and, if possible, cover with sifted compost, old hot-bed soil or, when dealing with clay, with sand or light sandy soil. Finish off by raking over the surface carefully and roll with a light roller.

It is not an easy matter to make or improve a lawn; it requires a lot of patience, hard work and knowledge, but it is surely worth while to make the attempt, because nothing sets off a garden so much as a well tended lawn.

If turf is fed, kept free from weeds and worms and, if the soil is heavy, dressed with charcoal, cinders, breeze or sharp sand, it will go a long way to produce the desired result.

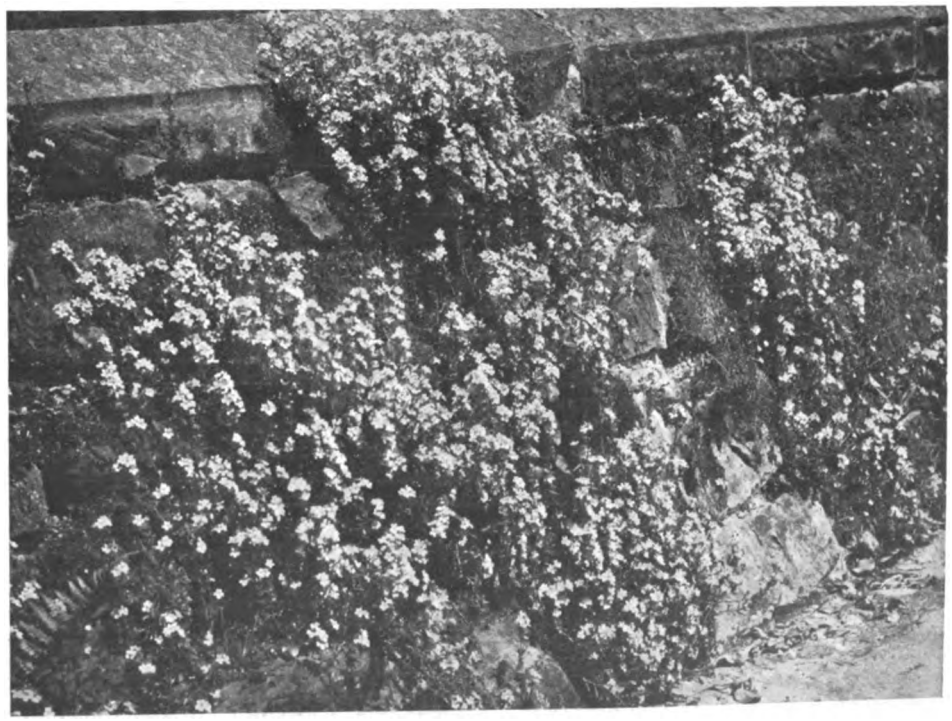
A BEAUTIFUL PLANT FOR WALL DECORATION

FEW alpine flowers are so amenable to wall culture as this little bright-coloured plant (Erinus alpinus) from the Pyrenees, which is easily established on such places by merely shaking a few of its seeds over the face of old walls, battlements, ruins and stony places.

It does not matter what the wall is built of really, so long as it lies dry and fully exposed. August is a good month for sowing or scattering the seeds, and the plants growing on the section of old sandstone wall here depicted were sown during that month three years ago. Here we get an abundance of ripe seed each year, and therefore we scatter it about in likely places with a lavish hand, often with charming results.

If scattered on walls already furnished with aubrietias, it succeeds those plants in bloom, and so we grow it in this way, also on old brick walls to which roses are attached it gains a secure footing and is annually a source of interest and charm, for in addition to the type which bears racemes of violet-purple flowers there is a very pretty white and bright rose variety.

Unfortunately, it is often planted on flat ground, which is fatal to this little sun-lover, as it invariably succumbs the following winter. E. MARKHAM.



MASSES OF ERINUS ALPINUS ON THE ROUGH SANDSTONE WALL AT GRAVETYE

LILIUM AURATUM

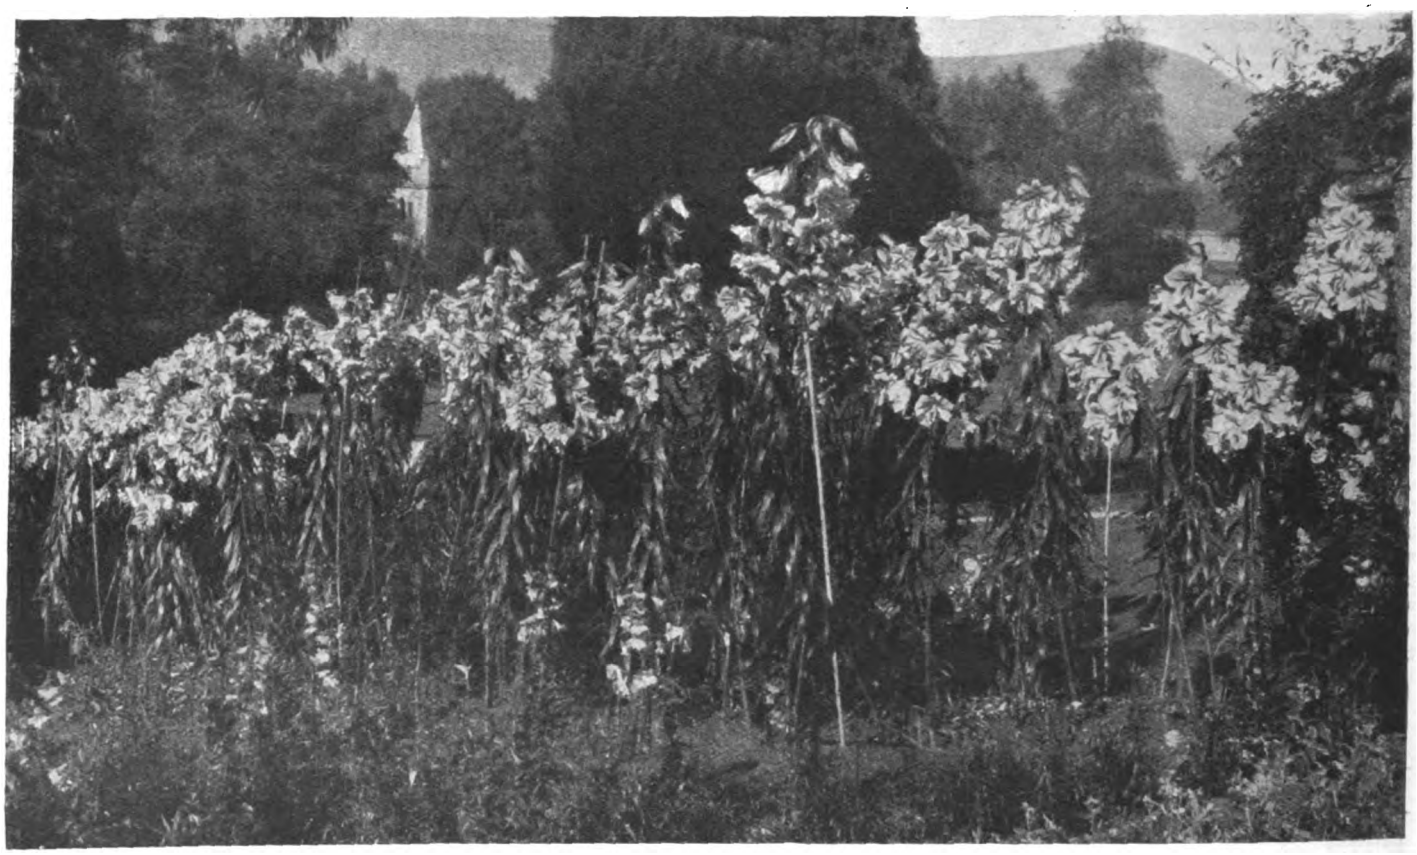
BY A. GROVE.

THE SECOND HALF OF MR. GROVE'S ARTICLE ON LILIUM AURATUM, WHICH HE HAS WRITTEN IN ANSWER TO THE CORRESPONDENCE WHICH HAS LATELY APPEARED IN "THE GARDEN."

(*Continued from page 75.*)

AS illustrating the transport difficulties the pioneers of the export trade had to contend against, the story printed in THE GARDEN, Vol. LX (1901), page 290, is illuminating. It is from the pen of Mr. Alfred Unger, then a well known horticultural merchant in Yokohama, and concerns an acquaintance of his, whom we may call Mr. X. Early in 1866, at his sat since, but, needless to say, I gave up exporting lily bulbs, though often requested to do so since."

The use of clay as a protective material for the bulbs seems to have been suggested by Dr. Alexander Wallace of Colchester, at that time an enthusiastic lily grower, and one of the originators of the New Plant and Bulb Company, a local



LILIUM AURATUM AT BRODICK CASTLE, ARRAN.

father's house in England, Mr. X. met a traveller who had just brought back from Japan a case of bulbs of L. auratum, which was the horticultural novelty of the moment. The traveller sold the bulbs at a guinea apiece—almost enough to defray the expense of the journey home from Japan. This so fired X.'s father that he told his son, who was about to sail for Japan, that he was to obtain a quantity of these bulbs and ship them home, the father being firmly convinced that he could sell them without difficulty. The sequel is best told in the son's own words: "To make a long story short, I collected, or rather had collected for me, about 400,000 bulbs, big and little, some of them very big, at a cost of one to three or four rin [coins of extremely small value] each. Not being able to return myself to Yokohama, I sent them down in a sailing ship my firm had chartered, with instructions to forward them by Peninsular and Oriental steamship through to Southampton. I had the cases packed so that the bulbs were covered with a thin layer of loose earth.

"Unfortunately the summer had been very rainy and the bulbs were full of moisture. My father contracted to sell the whole lot at from 1s. to 5s. a bulb, and went down to Southampton to take delivery; but to his horror there was not one single bulb left, only leaf-mould, and I lost my chance of making my fortune this first year. Besides this, I lost the freight, which amounted to £150, if I remember rightly. My father built a summer-house out of the cases, in which I have

concern which imported considerable numbers of Japanese bulbs. Aware that camellias were successfully exported from Japan to the Cape with the stems and leaves enveloped in clay, Dr. Wallace proposed a trial of the material with lily bulbs. It proved so satisfactory that it has since been extensively used, and, though by no means ideal if only because of its weight, the method brought importers' losses within reasonable limits. But of late years improved methods of stowing perishable cargo and greater care in ripening the bulbs have made it possible to return to the use of dry powdered earth as a packing material. Its use involves considerably less handling and labour, both to consignor and consignee, and before long it will probably entirely supersede the system of clay balling formerly in vogue. That method will probably always be necessary in the case of bulbs of early-flowering Japanese lilies, such as LL. japonicum and rubellum, for while they come on the Yokohama market in June and might just as well be exported then, custom ordains that the bulbs must be kept till the general export of lily bulbs begins in the autumn. To keep the bulbs from shrivelling during the intervening four months, the use of a clay envelope can hardly be avoided. From the date of the initiation of the Anglo-Japanese overland post, up to 1914, the writer frequently had parcels of bulbs of LL. rubellum and japonicum from Yokohama by post, *via* Siberia. They usually reached England about the middle of July and, provided the season had been favourable for the

Digitized by Google

ripening of the bulbs, arrived in excellent condition without any packing.

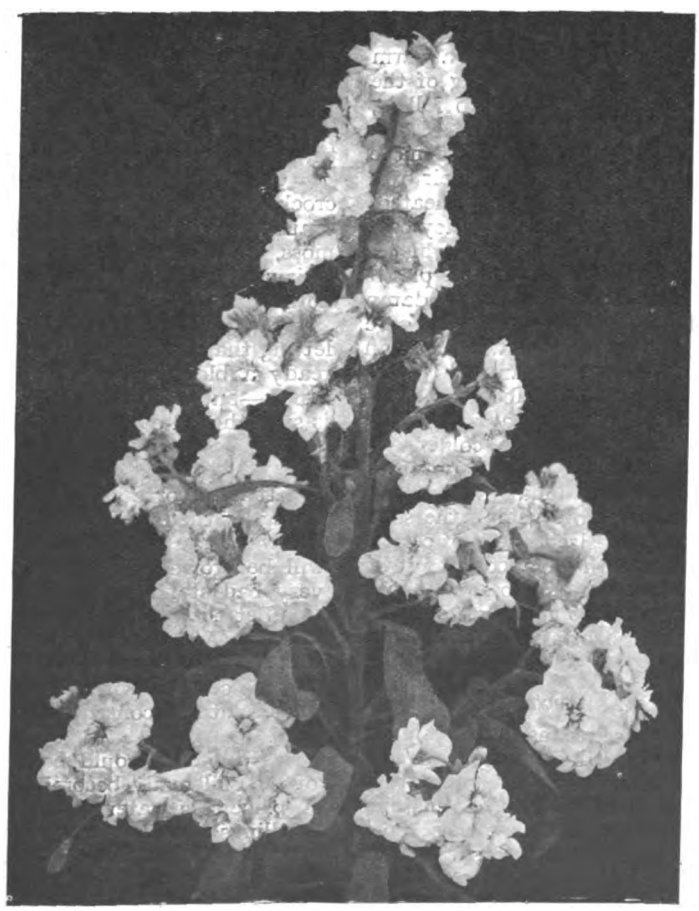
Once in the hands of the average gardener, probably not 5 per cent. of the bulbs of L. auratum exported from Japan ever see more than one year of existence—a deplorable state of things, due to a variety of causes. In the first place, when this species was introduced it was generally regarded as a pot plant, as was, and is, L. longiflorum. This was possibly due to a mistaken notion that such a gorgeous plant of the East could not be hardy. At that date, too, the cultivation of exotic lilies as garden plants was seldom practised. But whatever the reason, the tradition grew up that once they had made their first display as pot plants the bulbs were to be discarded, and so they were usually thrown on the rubbish heap—a a pernicious system still practised in numerous cases. Then again, the cultivation of L. auratum is but little understood, and so we see it planted in soils and situations where nothing can save it. Only a tithe of those who buy the bulbs realise that lime is as much a poison to it as to the majority of rhododendrons, and for some reason attention is seldom drawn to the point in the catalogues of those who sell the bulbs, or by those who write about them. The writer constantly sees it stated in print that " a suitable compost for L. auratum consists of equal parts of fibrous loam and leaf-mould or peat, with a liberal allowance of sand or grit." Not a word about lime, yet probably half the loam in the kingdom is charged more or less heavily with lime, as half the leaf-mould and much of the grit certainly is.

For reasons for which no entirely satisfying explanation has been forthcoming, L. auratum always seems to have taken more kindly to cultivation in Scotland than in England or Ireland. By a process of elimination we reach the conclusion that this must be due more to climatic conditions than aught else, for Scotland has no advantage over the rest of the kingdom or Ireland in the matter of soil, while English and Irish cultivators are as keen as their Scottish colleagues. In McNab's day, the Edinburgh Botanic Garden was famous for L. auratum, and at the present time it is doubtful if there is any colony of the lily in Britain comparable to that in Mrs. Lemon's garden at Brodick in the Isle of Arran, or in Major Fleming Hamilton's garden at Craighlaw. As lilies go both these are well established plantings, and, so far as the writer knows, there is now nothing like them south of the Border. In the 'seventies and 'eighties, Mr. MacIntosh of Weybridge was remarkably successful with L. auratum ; and Mr. G. F. Wilson, the enthusiastic amateur of lilies, to whom we owe the R.H.S. Garden at Wisley, cultivated them to excellent purpose at Heatherbank, Weybridge. But as a student of the genus, Mr. Wilson did not attach overmuch importance to the mere numerical superiority of one plant over another in the matter of blooms ; for, once a certain number is exceeded, the plant grows like a top-heavy giant, the stem becomes overloaded and loses both proportion and balance and, incidentally, the critic's respect. And there is no difficulty in persuading L. auratum to outdo itself. The point turns on feeding as much as anything else, and if your correspondent, Mr. London, as well as Mr. Clarke, who in the issue of THE GARDEN (November 29th, 1924, page 811) thought that a garden plant with twenty-seven blooms might constitute a record, will refer to your own columns in years past and to the columns of your contemporaries—a pleasant and profitable occupation for any gardener—they will find that such plants are not even in the first flight, for there are records of a garden plant with a single stem carrying seventy-eight blooms, and of a multi-stemmed pot-grown bulb with 208 blooms ; specimens with fifty blooms are common enough. No species seems more prone than L. auratum to that scourge of the lily grower's operations—fasciation. Plants afflicted with this malformation, which may be congenital, are robbed of their naturally beautiful habit and become the ill-shapen, mop-headed monstrosities so well portrayed in the photograph which accompanied Mr. Gunstone's letter.

EAST LOTHIAN STOCKS

I HAD not grown this stock previous to taking charge of an important garden in Scotland, but finding that it was regarded with great favour I decided to try it. This I did with more success than I expected, and was so impressed with its freedom of flowering that on returning to take charge of a garden in England I introduced the East Lothian stock. I gave it better treatment than I had practised in Scotland, and found that it was well worth the extra trouble. My method may be of interest to readers.

A good strain of seeds is imperative, and this is not difficult to obtain from our leading seedsmen on either side of the Border. The seeds should be sown some time during February. I have tried sowing in January, but did not find that there was any advantage in so doing. The seeds are sown in a shallow box or pan in the usual way, in a temperature of 50° Fahr. I always have a dread of damping with stocks, and to frustrate this I like to prick off the seedlings when they are quite tiny. They are then carefully planted in a box at 2ins. apart. As another precaution against damping I make sure that the boxes of seedlings are so placed that they do not catch any of the spray when other plants in the house are being syringed.



A FINE SPRAY OF EAST LOTHIAN STOCK.

The seedlings are kept in a warm house, but are given plenty of light and a position fairly close to the glass. Not until the young plants show a tendency to become crowded are they moved from the box. The plan then adopted may seem rather unorthodox (in fact, I regarded it so myself when I first tried it). It is to pot the plants into 3in. or 4in. pots, but in this case the end justified the means. If the plants are to receive no later potting they are put into 4in. pots, but if it is intended, as I advise, to give them the benefit of another potting, then the 3in. size is chosen, as there is then the opportunity of moving the plants into 5in. pots. I have even tried some in 6in. pots, but favour the 5in. for preference. Any good potting soil that is available at the time is used for potting the plants, and when they have started to grow in the new soil sufficiently for a few roots to be seen if a plant is removed from its pot, the plants are given a cooler and more airy atmosphere. Shortly after they are nicely establish-

Digitized by Google

in their 3in. pots they may be given cold-frame treatment. The removal of these pots will probably take place about the middle of March, and an endeavour should be made to get them potted into their larger pots before the end of April. This will give them an opportunity of being well rooted by the time they are planted in the beds, which will generally take place about the last week in May. I have usually had them commence flowering during the first week of June. This can only be done by sowing the seeds early. If the sowing is done at the same time as is usual for the ten-week stocks the season is well advanced before the flowering commences.

It is always a good plan to grow in pots several more than are necessary to fill the beds. This is advisable first of all on account of the possibility of some of the plants collapsing, as does sometimes happen, and also because there is an uncertainty about all the plants coming double. To a large extent this contingency is provided against by buying the seeds from a good firm, but no firm can guarantee more than a fair percentage of doubles. The plan of growing the stocks in pots and keeping back a reserve is an insurance against failure in this. The reserve plants should be kept in the pots till all the plants in the beds have shown whether they are proving to be double or otherwise. The pot plants will naturally show their flowers, and double ones can be substituted for single ones. Even then it is wise to keep a few in pots in case there should be a collapse of any plants later in the season. These reserve plants could be kept going with a little manure water, and if not otherwise required would flower well in the greenhouse.

The plants grown in the beds, as described, will produce one central spike and often there will be quite 12ins. of flowers. As this central truss goes out of flower it should be removed, when side growths will flower in profusion. I have counted over fifty flowering side growths on a plant at one time, and the plants themselves have measured quite 18ins. across. The flowers are very useful for cutting.

A very pleasing bed has been made by mixing these stocks with heliotropes. Standard heliotropes were planted at 4ft. apart, and the stocks at 2ft. apart, in square fashion. Centrally between four stocks were planted dwarf plants of heliotrope. The effect produced was quite pleasing, both from the point of view of flowering and fragrance.

There is not so great a variety of colours in the East Lothian stocks as there is in the ten-week, nor do I think that there is quite so much fragrance, but surely there is room in the ordinary garden for both kinds. I have had the East Lothians start flowering on June 1st and continue to do so till they were removed on October 23rd to make way for spring-flowering plants.

WILLIAM F. ROWLES.

HOW TO HAVE AN EARLY FLOWER GARDEN

TO ENSURE A PLENTIFUL SUPPLY OF FLOWERS IN THE EARLY SUMMER MONTHS, THE FOLLOWING CULTURAL HINTS SHOULD BE ADOPTED.

IN view of the need for economy, it is not unlikely that much of our formal bedding out will this year be replaced —and it can be very charmingly replaced—by using plenty of flowers of the "hardy annual" type. The question sometimes arises, "Can an *early* result in our flower beds be provided by these means?"

The present writer's opinion is based on experience and it is the only basis, certainly, which the Editor or the readers of THE GARDEN may be expected to accept. As an opinion it is, however, a little unusual, perhaps it may even be called paradoxical. For the truth seems to lie in raising the annuals for early display a very little *later* than is usually attempted.

One is not speaking now, of course, of cases where a warm greenhouse can be consecrated expressly to the raising of the stock required, with another of cooler temperature to follow, and cold frames to finish off.

One is thinking rather of the less luxurious but more usual conditions of those amateurs who like to do their own gardening, but have only one greenhouse (and that unheated) in which to attempt everything and to accomplish all they can. To such enthusiasts—and they are many—one would whisper in confidence: "Don't start *too* early, if you wish your plants to get ahead. January and February spell fog, frost, damp —and disaster! Begin this work in March—and with care and common-sense it is almost certain that you will have an earlier—and certainly a healthier—stock of annual plants with which to fill your borders than your neighbour who has perhaps adopted the more usual practice of January sowing."

These hints apply more particularly to the colder and wetter parts of the country. But conversely, if for any reason there has been delay in starting to raise annuals a month or two before March where conditions are more genial, the same practice can be applied of sowing a good-sized batch of certain of the more interesting sorts this month in a corner of the cool greenhouse or in a cool frame rather than to sow directly out of doors. And the warmer conditions may, generally speaking, be counted upon here also, to bring about the same speedy and excellent results.

PREPARING THE BOXES AND POTS.

The first step is to take pots or seed pans (or the shallow wooden boxes known as "flats"), and get them ready for sowing. If shallow boxes are preferred and none is at hand at the moment, the fishmonger may be found to "oblige" his customer with something very suitable; and the fact that these boxes have held salted fish will make them none the worse for horticultural purposes!

See that the pots, pans, or boxes are properly cleaned and ied, and also that their slits or holes are sufficient to allow water to pass away easily, since the first essential of this, as of practically all successful cultivation, consists in securing *free drainage*.

The next thing to do is to fill the pots or boxes with light soil prepared for the purpose. Good fibrous loam—the top soil of an old pasture—is the right material to form the staple, and with it should be mixed well decayed leaf-mould from the garden heap, in proportion of one in three parts (to lighten the mixture)—finally adding a twentieth part of sharp silver sand. This last is in order to keep the whole medium porous and "open"—again for the purpose of securing perfect drainage throughout.

These materials having been satisfactorily mixed upon the potting bench, the "compost" may be left for a day or two so as to become "warm." Care must be taken that it is neither too moist nor too dry when the moment comes to turn it over for the last time before putting to use.

Cover the drainage holes of the pots as usual with broken crocks (placed hollow side upwards), and on the top of this drainage material place a little half-decayed leaf-mould, or moss, or better still some of the fibrous part of the loamy soil. This will further prevent the fine soil from being washed away downwards and choking up the drainage.

Then proceed to fill up pots and boxes with fine soil, letting that for the very top be sifted with a fine sieve. Have ready a block of wood of suitable shape and press the soil firmly—but not so as to harden it—seeing, of course, that it is smooth and even before doing so.

ECONOMICAL SOWING.

It is important in sowing annual seeds to distribute these thinly, or there will certainly be a great deal of perfectly needless waste; and, more disastrous still, the individual seedlings will be crowded from the outset and consequently obtain a very bad start.

Let the seeds be covered lightly by scattering sifted soil, and pans and boxes can then be put in the greenhouse or frame, standing them as close to the glass as is possible. They may be covered with sheets of brown paper in order to protect from light and consequently to hasten germination in a healthy way.

No water should be given unless there is an appearance of the soil really becoming dry, and a syringe should be used in place of a water pot. Over-watering has ruined millions of seedlings; and if any sign of Pythium De Baryanum (the dreaded "damping-off" disease) should occur, the water supply must at once be decreased and more air be admitted. "Damping-off" will first be visible by some of the seedlings turning pale and then falling over sideways; the disease

Digitized by Google

quickly spreads in suitable conditions, but cannot flourish otherwise than in a warm, moist atmosphere.

So soon as the first true leaves are apparent between the "nursing leaves" of every seedling, transplanting or "pricking off" will begin. This means, of course, that each group of seedlings will be lifted carefully, which may be done by gently pushing the wooden label (on which its name is written) underneath the patch, and then planting each individual seedling (of the group lifted) an inch or more from its fellow in a fresh box of soil. The holes are naturally made with a small wooden dibber shaped like a blunt-pointed pencil, the rootlets of each tiny plant being allowed to "touch bottom" before the soil is drawn round them and pressed firm. This is usually done with the dibber and the first finger of the left hand—but care must be taken not to let the point of the former come near to the tender stem of the plantlet.

There are multitudes of hardy and half-hardy annuals which may be relied on to give a splendid show in the garden this summer. Some of them are useful for cutting, and most of them may be sown at the present moment in the way suggested, hardening off by standing in their boxes out of doors, and eventually planting out in April or May. HELEN COLT.

GREENHOUSE FLOWERS AT VINCENT SQUARE

THERE was a varied collection of flowers at the Royal Horticultural Society's Hall, Vincent Square, Westminster, on February 10th. Many were hardy, while others again were grown under glass. It being the occasion of the Annual General Meeting of the Society, there was a large attendance. Chief among the greenhouse flowers were the cyclamens, while from the unheated greenhouse came the numerous alpines in great variety with saxifrages much in evidence. Fruits and vegetables were also well represented, and various exhibits of a miscellaneous nature completed the extensive list of those showing. With the better weather during the past few days the majority of the flowers were in fine condition and were much admired.

There are many strains of cyclamen on the market, but few which can be called really reliable. Success with cyclamen depends largely on the quality of the seed, and unless the best is used the flowers will be few in number, poor in colour, and the percentage of germination will be low. The Caledonian strain of cyclamen has been introduced within the last twelve months. The value of this strain, which was raised by the Cyclamen Growers and Floriculturists of Luton, of which J. W. Forsyth is the manager, is rapidly being realised by an increasing number of people. Anyone who was present at the Show last week could not help being impressed by the excellent exhibit of the Caledonian strain. The size, brilliancy and purity of colour of the flowers were undoubtedly above the average. Not only were they exceptionally robust, but each plant bore a larger number of flowers than is usually found on plants of any other strain. Some of the frilled varieties were particularly charming and were superior to the old type of frilled, which was inclined to have drooping petals. The finest of the frilled varieties was Lady Helen Cassel, one of the latest introductions. The rosy pink flowers were borne on erect stiff stems, and the habit of the plant was very robust. The vivid scarlet of Scarlet Queen and the deep velvety crimson of Improved Brilliant would be considered by many people preferable to Queen Mauve with its large bluish pink flowers; but the question of colour is a matter of individual taste. From any other point of view there was nothing to choose between these three varieties; they were all outstanding in form, size and quality. One or two new varieties and several sports which were exhibited were interesting.

Messrs. Bath of Wisbech had a small but pleasing and well arranged stand of bulbs, including tulips, hyacinths, daffodils, crocuses, and Iris reticulata. The yellows of such tulips as King of the Yellows and Yellow Prince combined well with the colourings of the hyacinths and daffodils. Of the

A NEW VARIETY OF MERIT, FREESIA ORANGE KING.

THE EARLY FLOWERING PRUNUS AMYDALUS VAR. PRÆCOX.

Digitized by Google

narcissus varieties, Soleil d'Or (yellow), Fairy Queen and Sycamore (white) were outstanding.

Messrs. Reamsbottom's name has become synonymous with St. Brigid anemones, and it was indeed a pleasing sight to see a collection of these in all shades of colour, varying in size from 1½ins. to 3ins. across, and more especially to learn that they were cut from the open border. For a constant succession of varied bloom these St. Brigid anemones are excellent. They always call forth admiration at any season, and they are ideal for cut flower purposes. Their culture is so simple and the results so good that they should be more extensively grown.

Among the fruit exhibits, that of Messrs. Rivers and Sons attracted much attention. It consisted of large pot plants of various citruses. Well fruited specimens of St. Michael's orange, which is the ordinary orange of commerce, were chiefly in evidence, while a few large fruits of that singular variety, Embiguo (the Navel orange) were also shown. There were in addition several other varieties of lemons and oranges, representative of the large stock which Messrs. Rivers carry.

The Kabschia saxifrages, although not yet in full flower, were the chief interest among the alpines. Their appearance marks the real beginning of the year in the rock garden, for if we take S. Burseriana as the representative of the family, they show all the qualities for which we value the alpines as garden plants—the compact, neat design, relatively large flowers and cool brilliance of colouring.

Messrs. Tucker showed the variety Tridentina of S. Burseriana, which is second to Gloria only on account of its more widely separated petals which show a little daylight at the base; the variety crenata, with solid, wavy petals slightly scalloped at the edges; and more striking than either their new hybrid, Brookside. This, from the gardener's point of view, is a magnified Burseriana, a Gloria, its flowers are the largest of the group, but well formed of regular, overlapping petals, which, in spite of the parentage (S. B. Gloria and S. Paulinæ), are a pure, brilliant white.

Another fine, free-blooming hybrid is S. Burseriana sulphurea (S. B. Gloria × S. Faldonside), whose large flowers of cool, evening primrose yellow associate well with those of the type. Messrs. Tucker also showed some of the newer Engleria hybrids, S. kewensis, whose purplish pink flowers on long stems clothed with magenta hairs make a much more pleasing picture than the description suggests. S. Mariæ Theresæ is like it, but superior in the frostiness of its rosettes, though its flowers, of a purer pink, are a little starry. S. Boedkleri, another Engleria hybrid, is an oddity with small biscuit-coloured flowers suffused with red.

Messrs. Prichard's saxifrages were mostly their own hybrids of S. lilacina, the Himalayan that introduced a new colour into the group. S. Delight seems one of the best, with fairly large flowers of lilac pink on short stems. S. Gewgaw is unhappily named, for its pure white flowers with purple anthers are quietly beautiful and the whole plant is very neat and compact. Double flowers are not much desired in alpine plants, but the double pink Valerie Kevil has a great deal of charm and would make a good companion to Silene acaulis fl. pl. in a toy garden.

A single plant of Sarcococcus ruscifolius filled the air with a heavy tropical scent, though it is perfectly hardy. It is curious that it is so seldom seen in gardens, for it flourishes under trees and its polished evergreen leaves are cheerfully decorative throughout the year. Parochetus communis might also be seen more often, for, although it comes from Nepal, it seems hardier than might be expected.

Messrs. Waterer showed a good group of the purple Sisyrinchium grandiflorum against a background of Narcissus triandrus albus, some varieties of Iris Sind-pers, including a reddish purple one, rather flatteringly called "Ruby," and a well flowered bush of Osmanthus Delavayi, whose merits have already been described in THE GARDEN.

Messrs. Cheal built up a series of terraces and little cliffs of brown limestone, which they made very gay with Anemone fulgens, Rhododendron præcox, hybrids of Primula Juliæ and pink hellebores.

Among the other exhibitors were the following:

Azaleas.—Messrs. William Cutbush.

Carnations.—Messrs. Allwood Brothers, C. Engelmann, Stuart Low and Co.

Citrus.—Messrs. Thomas Rivers and Son.

Crocus.—Mr. E. A. Bowles.

Cyclamen.—Messrs. Stuart Low and Co.

Fruit.—Messrs. Bunyard and Co.

Irises.—The Rev. H. Rollo Meyer.

Nepenthes and Stove Plants.—Messrs. L. R. Russell.

Orchids.—Messrs. Charlesworth, Cowan and Co., Flory and Black, Lieut.-Colonel Sir George Holford, K.C.V.O., and Stuart Low and Co.

Polyanthus.—Messrs. G. A. Miller.

Rhododendrons.—R. Gill and Son.

Roses.—Messrs. Elisha Hicks and George Prince.

Shrubs and Alpines.—Messrs. Bakers, W. Cutbush, H. Hemsley, Carter Page and Co., G. Reuthe, R. Sheppard, G. Whitelegg, F. K. Wood, and Skelton and Kirby.

Topiary.—Messrs. John Klinkert.

Vegetables.—Messrs. Dobbie and Co., Sutton and Sons, and French Intensive Gardens.

NEW AND RARE PLANTS.

Freesia Orange King.—The flowers of this variety are of fairly large size with petals of good substance. In colour they are deep yellow tinged with orange which is well into the throat. They are borne on tall stiff stems about 1ft. in height and have a haunting somewhat peppery fragrance. It appears to be a very free-flowering variety. Award of merit. Shown by the Rev. J. Jacob, Whitewell Rectory, Salop.

Freesia Lemon Queen.—Another variety raised by Mr. Jacob. The flowers are of a delicate lemon yellow in colour with a delightful fragrance, not so pronounced as in Orange King. They are large and carried on tall erect stems. It appears to be a free-flowering variety and one of considerable merit along with its neighbour. Award of merit.

Prunus Pseudo-cerasus.—This is the typical form of this cherry, which was first described by Lindley in 1826, and the flowering sprays shown are taken from the only old plant in cultivation in this country, which is now a tree about 16ft. high in the Cambridge Botanic Garden. The flowers are borne on short racemes containing many blossoms, which provides for a long flowering period of over six weeks. In size the flowers are about ¾in. across, with the petals jagged at the apex. In colour they are white tinged with rose. The specimens exhibited did not show the real beauty of the flowers, as many were unopened. The stems are characterised by a number of warty growths. Award of merit. Shown by the Director, Cambridge Botanic Garden.

Salix cinerea var. Medemii.—This is a variety of the ordinary grey willow. Sprays of the male catkins were exhibited on naked shoots. These are silky and of much the same size as in the type, varying from ¾in. to 1¼ins. long and from ⅛in. to ¾in. wide. The variety is earlier flowering than the type. It is of no great beauty, as far as one could judge from the sprays shown. Award of merit. Shown by the Director, Royal Botanic Gardens, Kew.

Galanthus Byzantinus.—This variety is very close to G. Elwesii, probably intermediate between that species and G. plicatus. The flowering stems are long, carrying large drooping graceful flowers. The outer segments are oblong, with the apical lobes somewhat reflexed and crisped. Award of merit. Shown by Mr. C. T. Musgrave, Hascombe Place, Godalming.

Prunus Amydalus var. præcox.—This is a variety of the type which only differs in the fact that it flowers a fortnight earlier. The flowers are large, 1in. to 2ins. across. Each is carried on a short stalk. In colour the petals vary from rose to white. First-class certificate. Shown by the Director, Royal Botanic Gardens, Kew.

ORCHIDS.

Miltonia William Pitt, Stamperland var.—This beautiful variety bore four flowers of deep crimson colour, the base of the labellum yellowish. In formation closely resembling those of the well known M. vexillaria. Award of merit. Shown by Mr. Robert Paterson, Cathcart, Glasgow.

Cypripedium Gold Mohur (Goliath × Lady Dillon).—In this novelty the broadly developed dorsal sepal has an undulating margin bordered with white, the main area being deep amber yellow, with slight spotting of a dark purple colour; petals and labellum light brownish with a bright sheen. Award of merit. Shown by Mr. G. F. Moore, Chardwar, Bourton-on-the-Water, Glos.

Cypripedium Robert Paterson (Hera × memoria F. M. Ogilvie).—The white dorsal sepal of this flower is heavily spotted with crimson-purple, the base greenish, and the broad petals yellowish with the upper part shaded reddish brown. Award of merit. From Messrs. Flory and Black, Slough.

Cattleya Caroline splendens (Percivaliana × Enid).—The spike bore five large flowers in which the labellum was fully developed and of bright purple colour. Award of merit. From Messrs. J. and A. McBean, Cooksbridge, Sussex.

Cymbidium Redstart var. Crimson Lip (Dryad × Pauwelsii).—This pretty hybrid had a spike of twelve flowers, rose tinted, the labellum blotched with crimson, and the column rose coloured. Award of merit.

Cymbidium Butterfly, Westonbirt var. (insigne × Lowio-grandiflorum).—A showy plant, the spike carried no fewer than twenty-four large flowers of yellowish colour, the labellum marked with crimson. Award of merit.

Cymbidium Warbler, Westonbirt var (Gottianum × Holfordianum).—A charming hybrid, the robust plant bore two spikes, with five and seven flowers respectively, of light greenish yellow colour, delicately spotted, the labellum white with a few crimson lines and spots. Award of merit.

Cymbidium Curlew, Westonbirt var. (Butterfly × Alexanderi).—The spike bore eleven flowers of yellowish green tints, the labellum blotched and lined with crimson. Award of merit.

Cymbidium Lapwing var. roseum (Butterfly × Miranda).—A pleasing contrast of colour, the spike of seventeen flowers had the sepals and petals of carmine-rose colour and the labellum brownish with reddish spottings. Award of merit.

The last five plants were included in the wonderful group of cymbidiums shown by Lieutenant-Colonel Sir George Holford, K.C.V.O., Westonbirt, Tetbury, and to which a gold medal was awarded, with a silver-gilt Lindley medal to Mr. H. G. Alexander in recognition of his cultural ability.

CORRESPONDENCE

RHODOSTACHYS ANDINA.

SIR,—The plant represented in your issue of January 17th is Rhodostachys pitcairniæfolia, not R. Andina. It is figured in the *Botanical Magazine*, t. 8087, and is easily recognised by the brilliant red of the smaller innermost leaves at the time of flowering and also the bright violet-blue of its petals. R. Andina has pink flowers and the inner leaves remain green. Its leaves are covered on the underside with white scales which give the plant a silvery effect very distinct from that of the dark green of R. pitcairniæfolia. R. Andina is figured in the *Botanical Magazine* in t. 7148, and a good illustration of it appeared in the *Gardeners' Chronicle* for July 20th, 1918, page 24, from a plant that flowered in the Cambridge Botanic Garden. I have grown both these species in the open with slight overhead protection in winter for many years, and find R. andina much the hardier of the two. I saw several plants of R. pitcairniæfolia in flower in Mr. Arkwright's garden near Plymouth in January.—E. A. BOWLES, *Waltham Cross*.

IRIS TINGITANA.

SIR,—I wonder if any of your readers have found difficulty in flowering Iris Tingitana. I have treated the bulbs like freesias, grown on in a cold frame, and brought into moderate heat, but though they throw up strong growth, I get no flower. I hear that my neighbours have the same trouble, though they have tried stove heat and the bulbs came from another source.—B. K. G.

ALUM FOR SNAILS AND SLUGS IN THE GARDEN.

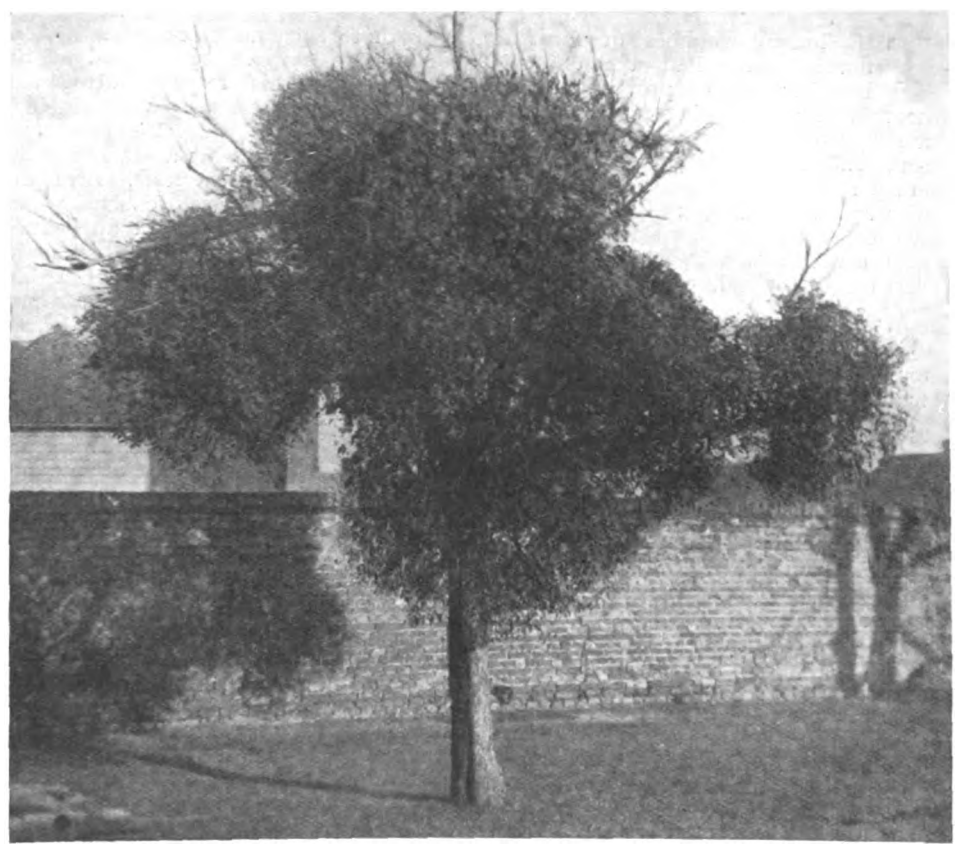
SIR,—Alum is applied in the powdered state merely because it is the most convenient form in which it can be used dry. In this state it is, of course, a little dearer than in the lump, but anyone who cares to take the trouble may very easily reduce the lumps to a fine powder by pounding or grinding. But for use in the liquid state this is unnecessary.

So far as I have been able to make out, the alum loses its effect after a time, but I cannot say precisely how long. So long as it remains dry, however, it appears to be quite effective, and the renewals of the sprinklings are a very simple matter. The main point, however, is that it *destroys* the pests, and that every time an application is made there is a reduction in the numbers, whereas such things as salt, soot, etc., are merely preventives. If plants are sprinkled with it before rain, the material is, of course, washed off, but in the process it is carried into the soil, where there is a good chance of it reaching some of the pests, and more especially of their eggs, which is equally important, while the foliage seems to be made distasteful to them for the time being. I have tried it on isolated strawberry plants growing near a grass edging in which slugs and snails harboured, and I found that an occasional sprinkling around the plants effectively protected them against attack, while in the case of unprotected plants the fruits were all eaten. I have no glass except a cold frame for general purposes, but I have found that alpines, for which slugs and snails have a particular liking, especially in the seedling stage, such as campanulas and gentians, may be completely protected against their ravages by occasionally sprinkling the ashes on which the pots stand with the powdered material. Or, if the frames are infested with them, a thorough drenching with a strong, hot solution after the plants are cleared out will destroy every vestige of them. I have also tried it with excellent results in rockwork.

It would, of course, be difficult to enumerate all its possibilities, but I should say that for the protection of valuable plants under glass it would be invaluable, and would be a great saving when one takes into consideration the time involved in hunting for the pests, or even in trapping them in various kinds of feeding materials.—A. D. RICHARDSON.

MISTLETOE ON APPLE.

SIR,—I think perhaps this photograph of an old apple tree covered with mistletoe may be of interest to your readers. It was taken just before Christmas last, and although it is difficult to distinguish the berries, they are unusually abundant. The mistletoe was started on the tree about fifteen years ago, and has now, as you will see, practically covered it. The tree is on an asphalted road leading to the stables, and although there is constantly a disturbing element, a mistle thrush built her nest in the tree and brought up a family of five during the late summer, and apparently she and her family are now fancying they have a right to partake of the berries.—J. W. BUCKHURST, *Biddenden, Kent*.



AN OLD APPLE TREE DRAPED WITH MISTLETOE.

DIGGING AND TRENCHING.

SIR,—In his admirable article on "Winter Work and Planting," Mr. Beckett advocates very strongly the bringing up of the under soil in trenching ground. This is no doubt sound advice where the soil is equally good with the top spit. I am afraid, however, that some reading the article and knowing Mr. Beckett's ability as a grower may not take this into consideration. Cases can be instanced where trenching made it almost impossible to grow anything for a year owing to the poverty and clayey nature of the subsoil. Unless the bottom has been double dug and well broken up for some years, it is much better to leave it below. But by all means break it up, and add to it any opening material possible, thus increasing the root run and also allowing superfluous moisture to pass readily into the drains.—J. H.

SYMPHYANDRA PENDULA.

SIR,—Being a devout admirer of the late Reginald Farrer both as a writer and an authority on rock gardens, I read with interest his fascinating eulogium on Symphyandra pendula, and on visiting his garden at Craven was pleased with its appearance growing on the cliff, so I resolved to grow it. I procured seed and raised a large number of plants, some of which I gave to friends. The plants did not flower till the third year and I must confess to having been sadly disenchanted with the result. There was a profusion of blooms which lasted only a few days, and were far from thrilling in colour. One of my friends who has a lovely rock garden at Bridge-of-Earn, makes the same report and threatens to throw it out altogether. I intend to give it another chance, and have planted it high up on a wall and will await the result with interest. Need I say how much I enjoy the numbers of THE GARDEN.—J. PATERSON.

MEDICINAL HERBS.

SIR,—I hear from so many sources that there is really a market in England for medicinal herbs. As it is, all our native healing plants are bought from France and other Continental countries. Take camomile as one example. It is now sold wholesale in London at £6 the hundredweight. I am told that there are several wholesale dealers in London who would be willing to buy plants grown and dried

Digitized by Google

Britain. I have this morning received a letter from a friend who constantly uses camomile and who until recently procured it from friends in Brazil, where, as on the Continent, every garden has a patch of this plant. My friend writes: "Cannot you get someone to write up this subject? It is so maddening to know how ignorant everyone is about medicinal herbs, and what might be done if only the right people would take it up." Again, violet leaves are excellent as poultices for all bad bruises, sores and ulcers. Many years ago I was told when visiting in the North of Ireland what a wonderful help such poultices are in cancer cases. Since then I have frequently heard the same in France, and quite recently in England I have heard of cases where violet leaves gave relief when all else failed. Some doctors, if not all, acknowledge their efficacy and order their application. Yet for those who require them and do not possess a garden, it is a difficult thing to procure a regular supply. Just now I am very anxious to find out where I can obtain fresh violet leaves, 2½ oz. of which are required every day. If violet plants were grown in health gardens, one could always be sure of getting a fresh supply of leaves.

Before the war France obtained most of her medical plants from Germany, with which the Fatherland was well supplied, as it was with all other necessities during its forty years' preparation for the Great War! I happened to be staying in a large country house in the North of Germany at the end of July, 1914, and during the first fortnight of the war had somewhat unique opportunities of seeing *how* prepared Germany was for the war in many ways. One was in the growing, drying and packing of medicinal herbs, in which the children in every country school were instructed. A plot allotted to the purpose belonged to the school. The plants were collected, dried and carefully packed by the children and then sent to a local centre, which forwarded them to the headquarters of the trade (a Government concern, of course), from whence they were exported to other countries, chief among them being France. I was told by one of the chief instigators of a like scheme which is now carried on in France that even after the outbreak of war medicinal herbs still poured into France from Germany, as she then did not grow sufficient for her needs. Now it is otherwise, and every French Department has a branch of the society which aims at making the cultivation of medicinal herbs a national industry and seeks to instruct the people to that end by means of botanical excursions, demonstrations and publications. — VICTORIA SLADE.

THE MANURE PROBLEM

THE limited supplies of farmyard manure have had the effect of bringing into prominence the necessity for employing other means to augment or maintain the fertility of the soil. Efficient manuring to-day involves much more than periodical applications of farmyard manure; it is an exact science, requiring much skill and intelligent concentration in order to get the best out of the soil.

THE FUNCTIONS OF MANURES.

It is necessary here to mention that one particular manure, or a mixture of manures, cannot suit every soil, and seasonable influences play their part largely.

It simplifies matters when studying manures to divide them into two classes:

1. Substances that benefit the soil and also the plant.
2. Substances which usually only benefit the plant.

In the first class are farmyard manure, shoddy, vegetable refuse and lime.

In the second it is necessary to include most of the artificial manures.

On some soils it is possible to keep up their fertility by the judicious use of the substances in the first class. But on no soil it it possible to do this over a prolonged period with substances in class two.

It is as well to point out here that, generally speaking, efficient manuring—improving poor soil and crops and maintaining the fertility of a good soil—consists of applications of substances in Class 1, supplemented by applications of artificial manures. If every cultivator of the soil would only grasp these first principles, there would not be so many rigid condemnations of artificial manures.

THE FOUR GROUPS OF ARTIFICIAL MANURES.

Many substances have been introduced during recent years as artificial manures, but, fortunately, they can be placed into four groups according to their effects upon plants and on the soil.

1. NITROGENOUS MANURES. — The function of all nitrogenous manures is the same—to encourage plant growth. In some cases it is possible to stimulate growth to such an extent that attacks of insect pests can be defeated by the plants. In this respect nitrogenous manures are particularly valuable in a late, cold spring, when the growth of plants is practically at a standstill and at the mercy of many pests. Leaf producing crops, such as cabbages, are peculiarly responsive to an application of these manures in spring, and many gardeners realise the effect of a late application of nitrate of soda for promoting a deep green colour to the leaves, making them more tender and crisp, and, incidentally, many exhibitors owe their success to late applications of nitrogenous manures.

The chief representatives in this group are nitrate of soda, sulphate of ammonia and nitrate of lime. They are all quick acting and should only be used when the plant is capable of utilising them and then always in small quantities. Large quantities produce a deep green colour in plants and to the inexperienced this effect may appear good, but it exposes the plants to attacks of fungoid diseases, and, in the case of potatoes especially, the crop suffers considerably by large applications.

2. POTASSIC MANURES.—The effect of applications of these substances — although perhaps not so striking as in the case of nitrogenous manures—are valuable chiefly for the vigour they give to the plant. They tend to produce hardiness in the plant, thus protecting it largely from attacks of disease, and are specially useful to all sugar and starch producing plants, such as potatoes, carrots, beet and pod-producing crops. On light, stony and "thin" soils they are indispensable for good results, and greatly lengthen the growing period, especially in the case of potatoes, where a light soil causes the tops to end their growth prematurely, long before the growing season is spent. The chief manures represented in this group are sulphate of potash, muriate of potash and kainit.

3. PHOSPHATIC MANURES.—Some of the effects of phosphatic manures on the plant are directly opposite to those of potassic manures—for instance, they are invaluable on heavy clay soils and in wet and cold conditions for hastening maturity and promoting early growth. They should be used cautiously on light, dry soils, as maturity may be adversely hastened and the yield depressed. Phosphatic manures are, at the same time, necessary on some light soils, and their use is imperative when potatoes are grown; they should, however, be used in conjunction with potash and farmyard manure. In districts where the rainfall is heavy, phosphatic manures are largely used with extraordinary success, which is accounted for by the rapid expansion of the root system of plants. Applications of phosphates also increase the food value and quality of many crops.

The popular manures supplying phosphates are superphosphate, basic slag, guanos, mineral phosphate, and bones in various forms.

4. COMPLETE FERTILISERS OR MIXED MANURES.—These usually consist of some of the artificial manures already mentioned, mixed in various proportions to suit the needs of crops and soils in varying conditions.

The above groups represent only artificial manures, which, as stated previously, usually only benefit the plant and not the soil, and it is therefore necessary to consider the organic and other substances which benefit both.

Farmyard manure must take pride of place here, and if green manuring and shoddy are included it is doubtful if there is any other substance capable of adding materially to the physical properties of the soil as well as feeding the plants. There are several other organic substances used as manure, but considering the small quantities applied to the soil, they cannot be said to affect the physical properties to any measurable extent.

THE USE OF LIME.—The falling off in the use of lime is difficult to explain, since most gardeners and cultivators of the soil know its value. It is absolutely necessary for correcting acidity and sourness in soils and maintaining its fertility. There are many forms of lime, such as quicklime, limestone and chalk, hydrate of lime and lime ashes. The most suitable form to use depends on many factors, which will be considered later. H. C. ELSDON.

THE AMATEUR FLOWER SHOW

PERIODICALLY the Royal Horticultural Society is criticised for not catering more for amateur exhibits at their shows, and in the past there has been a certain amount of justice in this criticism. It is true that such well known exhibitors as Sir George Holford, Baron Schröder and the Hon. Vicary Gibbs have always been to the forefront, but they garden on a large scale and are specialists in their various subjects. The ordinary amateur who gardens in his spare time has had little chance of exhibiting at Vincent Square except in the case of new and rare plants.

This year the Royal Horticultural Society is, for the first time, holding a flower show at Vincent Square solely for amateurs—on Tuesday, June 30th, and Wednesday, July 1st. The schedule is divided into forty-two classes, and a little examination will show that the schedule has been made out mostly for the small garden. Of the forty-two classes only eleven are open to all amateurs; of the remaining thirty-one, twenty-four are open to amateurs whose garden wage bill does not amount to more than £4 a week, while the other seven are only open to amateurs who employ no permanent gardener. This skilful arrangement of classes does away with any fear on the part of the exhibitor that he may be swamped by exhibits from large gardens whose owners specialise in some particular branch of horticulture.

The various classes are divided into roses, delphiniums, sweet peas, gladioli, shrubs in flower, herbaceous plants, plants grown under glass, hardy annuals grown in the open, orchids, carnations grown under glass, hardy pinks, foliage plants in pots grown under glass, ferns in pots grown under glass, violas or pansies, antirrhinums, pans of any one genus of hardy plants, gloxinias, begonias, large-flowered mimulus, fuchsias, native British plants, succulents, group of flowering and foliage plants, best new plant introduced into this country since 1914.

This list is extensive enough to suit every type of amateur gardener, and it is to be hoped that they will take advantage of it and exhibit in numbers. One of the troubles about amateur exhibits has always been the fear that such a high standard has been set by the trade that no amateur exhibit can compare in quality and in freshness on the day of exhibition. This is not the case, although, only naturally, the trade are accustomed to grow plants specially for exhibition. There are, however, several tips which may help prospective exhibitors and THE GARDEN will publish shortly an article on the preparation of flowers for exhibition and, nearer to the time, another article on the packing and carriage of flowers for exhibition purposes, both of which we hope will be of use to our readers who may wish to take part in the show.

It is to be hoped that exhibits will be staged in such quantities that this Amateur Flower Show will become an annual event, for good as we are as a nation at gardening there is always room for improvement, and the class of garden for which this show is being held is the most numerous, and so the most important, in the country.

I mentioned a week or two ago how seedsmen used constant selection in order to keep a plant from deteriorating in constitution or in order to improve its quality. In this way they help the amateur. In the same way the R.H.S., by holding this exhibition, are helping the amateur by showing them how a little healthy competition among themselves helps to keep up the standard of gardening. However good the quality of seed or plant may be, careless cultivation will ruin its chance of being a perfect plant, and gardeners, whether amateur or professional, are often inclined to set too low a standard in their garden. As a nation we are noted for the quality of our goods, and nothing except the best should be aimed at even in a hobby like gardening. Country horticultural shows have for long scheduled classes only open to amateurs, and this has always been good for horticulture. Now that the R.H.S., the premier horticultural society of the world, is holding a flower show solely for amateurs, it rests with the amateur to show what he can do.

Schedules may be obtained from the office of the R.H.S., Vincent Square, S.W., and entries, which must be made on the entry form enclosed with the schedule, must be received not later than June 2nd.

FRAGRANCE IN THE GARDEN

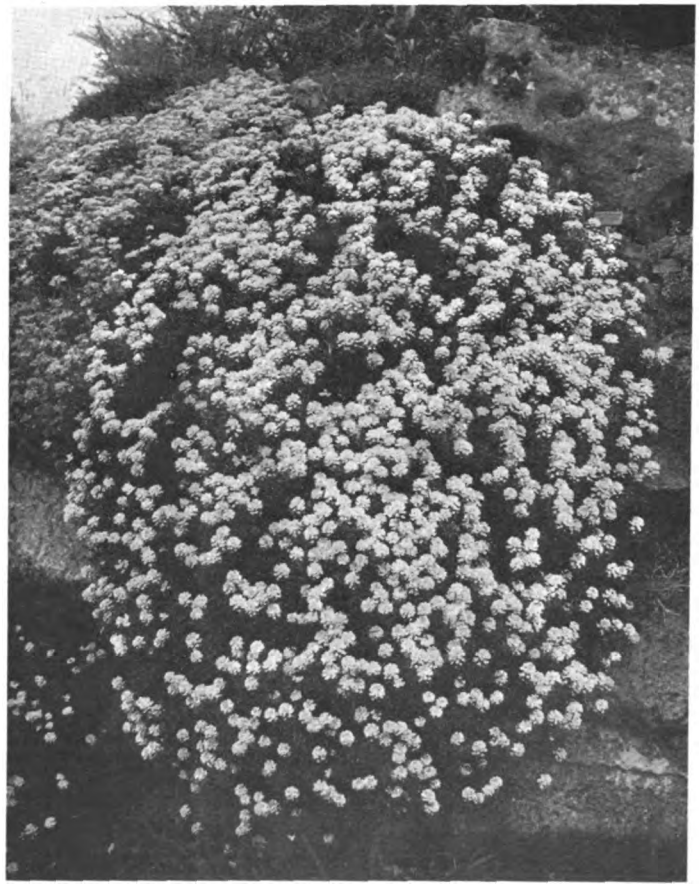
FRAGRANT FLOWERS ARE AGAIN BECOMING SO POPULAR THAT THIS ARTICLE ON SWEET SMELLING ANNUALS AND BIENNIALS SHOULD BE OF GREAT ASSISTANCE TO OUR READERS.

ANNUALS are very much like the Cinderellas of the flower world and, in common with their prototype, often surprise us by blossoming out into the Fairy Princess. Many striking qualities are caged within those hard shrivelled cases that we know as seeds, and the first sprouting green leaves give but little indication of the wealth of colour and store of fragrance that are the ultimate end of their development. But the grand truth is that it is all there and we shall find that for bold patches here and there in the borders, filling entire beds, or for the more humble rôle of carpeting, the fragrant annual is well to the fore.

In reading through a seed list alphabetically, the first name we shall probably encounter will be Abronia umbellata, a little used but valuable half-hardy annual with rosy purple flowers, that gives a fine effect when used as an edging or is equally effective when displayed in a basket. Its relative, arenaria, is a perennial, but may be flowered from seed the first year by sowing early under glass. In this the flowers are yellow and, in their perfume, closely resemble honey. Sweet alyssum amply justifies its name, and for carpeting in all sorts of positions is without an equal where a light-coloured floriferous and fragrant plant is desired. This is of the perfectly hardy class and may be sown outdoors in April where it is to bloom. It is seldom necessary to sow a second time, for self-sown seedlings are so abundant that it is easy to pick up and transplant as many as one wants.

In our estimation of the common cornflower, do not overlook its scent, for this is a very real quality, as may easily be proved by gathering a bunch and smelling the flowers. Not powerful, perhaps, but distinctive and refreshing. Candytuft provides a good range of colours in purple, rose, flesh pink and white, and all of these are highly fragrant. Considerable variation is found in the heights of the different varieties of this, a fact that—coupled with the colour range—makes it possible to use them in many different parts of the garden. The varieties that produce long spiral heads, instead of the flat spreading ones, last infinitely longer and preference should be given to these. Requiring to be started in heat and planted out later, when the weather has become warm, Datura Cornucopia is deliciously fragrant and produces large and exceedingly handsome deep purplish flowers. These smell as powerfully as any lily and present a most unusual effect when seen in full flower in a protected corner. It must be remembered that these daturas are really tender plants and are unsuitable for planting in exposed spots where they have to battle against strong winds, the result of which will be failure to flower. Another variety that is well worth a trial is Datura meteloides, which reaches a height of 3ft. and bears large white fragrant flowers that are tinged with violet.

Erysimum Perofskianum is a delightful wallflower-like annual, just over a foot tall, that, in addition to providing great splashes of brilliant orange, scatters its delicate fragrance all round the spot where it is sown. This is perfectly hardy and one of the few annuals that look at home when sown in the rock garden. One cannot go wrong in sowing the wonderful night-scented stock, Matthiola bicornis, for this has one of the greatest of all evening perfumes that any garden can boast. Some of the most up-to-date seed lists include our old friends, the stocks, under matthiola too: so that it will be convenient to mention them here. Here, indeed, is a rich store of beauty and fragrance, and one can never have too many of these, especially if they are doubles; although, from the point of view of perfume, the singles are quite good. One scarcely needs to point out the value of the stock as a bedding plant, but we may suggest that they never look better than where used in bold masses, either of one colour or in mixture, the most artistic result always resulting from separating the colours. In addition to the summer-flowering kinds, do not omit the splendid Brompton strain, which is so useful for spring and early summer flowering, before the ten-week varieties begin blooming. Mignonette is in place everywhere and falls into line with the alyssum as a splendid carpeting plant. The roots are of the shallow order, so that we may safely employ it as an underplanting between roses, etc., wherever a beautiful and fragrant plant is desired. Its neutral colour is an especially useful characteristic, for there is no risk of clashing and it will "go" with literally everything. Where this favourite annual does not prove a success and the growth is of a sickly yellow hue, it is usually an indication that the soil is lacking in lime and a generous application of this will result in free growth and flowering.



SWEET-SCENTED CANDYTUFT IN THE ROCK GARDEN.

Mirabilis jalapa, the Marvel of Peru, is a handsome tuberous-rooted perennial that may be successfully treated as a half-hardy annual and gives splendid plants about 2½ft. in height, with funnel-shaped flowers in late summer. These flowers do not open until evening and are borne in clusters of from three to six, varying in colour from red to white and yellow. Each flower is enclosed within a calyx consisting of five divisions, which continues to grow after the flower itself has faded, thereby adding to the attraction of the plant. Treated like the dahlia, the plants may be kept for several years. Mention must be made of the nicotianas, the finest and most fragrant of which is unquestionably the favourite white tobacco, so familiar to all lovers of fragrant flowers. Here again we want to emphasise the value of massing in quantity, for no plant gains more by the company of its fellows than this. It is true that one does face rather a large patch of closed drooping flowers during the daytime, but ample compensation awaits us for this each evening when the hundreds of starry flowers open in their glory and fill the air with their own particular odour. This is a generous plant, with odour enough and to share, and as one passes along the street or sits in a neighbouring garden, we may often revel in the delight that has been provided by a brother flower lover. Nearby or used as an edging to our tobaccos, we may use another

Digitized by Google

night-blooming annual, Nycterina capensis, which reaches a height of about 1ft. and bears a profusion of lovely white flowers that give forth the perfume of vanilla. These evening flowers are an education in the art of wide advertisement, for not only do they proclaim to the various night-flying insects that the store of nectar is open, by disseminating a penetrating odour, but they are invariably white or light-coloured. Another example of this publicity is to hand in the unique Schizopetalon Walkerii. This is a half-hardy annual that cannot be transplanted, for the roots are so delicate that it is impossible to move it successfully. This means that we must sow rather late, in finely raked soil and a sunny position. Take care that you do not mistake the small seedlings for weeds, for they are very grass-like in appearance during the early stages. The only care that will be necessary is to thin out the plants to 6ins. apart, so that they can branch freely. The flowers, as has been said, are unique, resembling nothing so much as exquisite squares of finely cut lace. During the day one would pass by the plant again and again without observing it; but wait until six o'clock in the evening and a great surprise would be experienced. With the regularity of a clock (more reliable, indeed, than many clocks we know) those greenish petals unroll and reveal the white squares described above. Did one fail to see them, the plant cannot escape notice, for the powerful almond perfume hangs heavily upon the air and one is bound to search for the origin of so much sweetness. The flowers are in small sprays that continue to expand, one after another, while the branching habit also ensures a long flowering season.

FOR A STORE OF BEAUTY AND FRAGRANCE IN THE GARDEN, STOCKS ARE UNRIVALLED.

Three more prominent "sweets" still remain to be dealt with—the sweet pea, the sweet sultan and the sweet scabious. The latter, it is true, is not strictly an annual, but responds so readily to treatment in this way that we may include it in our consideration of such plants. Unrivalled for cutting and freedom of flowering, it is one of the finest of all our fragrant flowers and a border in which there are some generous plantings of these may well "hold its head high" where successful beauty is concerned. With these, we always like to purchase our seed in separate colours rather than as a mixture, for this enables all poor or muddy colours to be eliminated and far better effects from the border and from the home decorator's point of view are secured. Sweet peas need no praise or description, but, from the point of view of our present purpose, another problem does arise—the sweetness. Lists are far too prone to emphasise the number of "fours," the depth of the colour, or the fact that the blooms "do not scorch," leaving out of account the prime reason for the flower's existence. Here and there one does find tucked away an allusion to "very fragrant" or "the real sweet pea perfume," and it is still possible to amass, say, a good dozen first-class varieties that are worth their weight in gold, compared with their sisters which rely solely upon exterior beauty for their charms. Each and every sweet sultan that can be found may be relied upon as a good border annual, with the single proviso that they should be sown in autumn in preference to the spring. It is thus that the plants attain those noble bush-like proportions and provide such a lavish display of their elegant flowers, which are good both in the border and when cut. The delicacy of their colours, long stiff stems and soft yet pleasing perfume, leave nothing to be desired. H. W. CANNING-WRIGHT.

PLANTS AND PEOPLE

IN the first number of THE GARDEN for 1925, Colonel Enever Todd in "A Wanderer's Note Book," turns aside from his pleasant discourse upon plants and places to ask, a little querulously, "Who and when was Bauhin?" One cannot help suspecting that Colonel Enever Todd knows quite well who Bauhin was (or rather, who they were), and is only putting his tongue in his cheek to add emphasis to a diatribe against the practice of bestowing names of people upon plants, for, although the brothers Jean and Gaspard Bauhin lived some three hundred years ago, they were of such renown in their time, and since, that it seems too soon for their memory to be claimed by "the iniquity of oblivion that blindly scattereth her poppy." They will always be known to the historian of botany by the 'Pinax Theatri Botanici" and the "Historia Plantarum nova et absolutissima," though Bauhini, Bauhinia and Bauhinorum may become empty names to the gardener.

Most people will sympathise, and many will agree, with Colonel Todd's objections, for there are many plant names of personal attribution that are no more than meaningless labels to most of those who use them. Yet some of the shortcomings of these names are not inherent in the method of naming, but are due to clumsy or partial latinisation.

It was easy for the botanists to give their names to plants in the days when they wrote gossiping letters to one another in Latin and signed their names in Latin form, when Charles de l'Escluse naturally called himself Clusius and his tulip, as naturally, took the name *Clusiana*. But we are unaccustomed nowadays to see our surnames in Latin dress and hardly recognise Mr. Strangeways in "Stranvæsia." Yet, since we have accepted Latin as the international language of botany it is surely better to conform to the old fashion of latinisation rather than to pass into currency names like "Haworthia," which are pronounceable only by ourselves.

Various shifts have been used to overcome the difficulty of latinisation. Rosa Ecae contains the initials of Mrs. Aitchison, the wife of Colonel Aitchison, who discovered the rose during his exploration of the Kashgar valley. The late Mr. Reginald Farrer created "Reginella," from his christian name (a happier coinage was "Bardolphii," which describes the countenance of a cypripedium especially distinguished for its whelks and bubukles), but neither of these are official and perhaps they have already passed out of use.

Colonel Todd strongly advocates that plants should be named after the localities in which they are found, but here again latinisation is a difficulty and we meet names like "Haylodgensis," which is inexcusable, even for a hybrid. Place names and descriptive names have the very great recommendation that they tell us at first glance something about the plant, but it seems a little ungenerous to grudge a botanist or plant collector the enduring memorial of a plant named officially in his honour. If we are really interested in a plant, most of us will be willing to take the little trouble required to find out how it got its name, and often the plant gains for us an added interest by its association with some part of the history of botany or gardening.

Linnæus laid it down that if personal names were given to plants they should be those of botanists or of patrons of botany, and he honoured many of his fellow workers in this

Digitized by Google

way. To the brothers Bauhin he gave Alsine Bauhinorum, because it was a plant with grassy leaves that grew on the mountains, and thus commemorated Gaspard's interest in grasses and Jean's work among the alpine flora. Perhaps the reason for the ascription is only one of the many legends that grew up round Linnæus' nomenclature, though it is quite consistent with his, sometimes whimsical, genius for giving appropriate names. The precepts of Linnæus have been faithfully followed in the making of official names, and it is perhaps worth while to draw attention to a discrimination that is expressed in the form of those specific names which are of personal origin, since it does not seem to be quite generally recognised. A genitive ending indicates that the plant was discovered or first described by the person whose name it bears, while an adjectival ending means that it was named in honour of someone, usually of someone who was concerned with its introduction or its classification. Thus the specific name of Iris Forrestii shows that it was discovered by Forrest, who is still adding to the long list of new plants that he has collected in China, while I. Hoogiana takes an adjectival ending because it was named, by Mr. Dykes, "after the two brothers Hoog, who now constitute the firm of Van Tubergen in Haarlem and it was due to their enterprise that the iris was imported from Southern Turkestan where it was discovered by their collector, Graeber." The genitive ending is usually retained when the plant is named in honour of a lady, as are Rosa Ecae, Berberis Wilsonæ and Ceratostigma Willmottiæ, for the distinction would be lost in the adjectival form, but, unfortunately the genitive is occasionally used without this justification.

F. A. HAMPTON.

GENTIANA PYRENAICA

BY CLARENCE ELLIOTT.

IT is curious that such a beautiful plant as Gentiana pyrenaica should have remained for so many years practically unknown and ungrown in English gardens. I remember it as one of the special treasures at Backhouse's nursery about twenty-five years ago, and it was there looked upon as a great rarity and extremely difficult to grow. Since those days I have never met the plant either in gardens, conversation or books. Farrer describes it in his "English Rock Garden," but I never heard him speak of it, and I never saw it in his garden, nor, I think, is it mentioned in any of his other writings. I do not think Farrer ever grew Gentiana pyrenaica, and I very much doubt if he ever saw it, which makes his description of it in his "English Rock Garden" all the more wonderful, for it is extraordinarily true and vivid.

For years, then, I had been wanting this elusive, lovely plant, and there seemed nothing for it but to go and get it for myself—which, after all, is far the pleasantest way of acquiring an alpine. In the first week of last July, therefore, I set out for the Pyrenees, making for the eastern end of the range, where alone the plant is to be found, and in particular for the little fortified mountain town of Mont Louis, which had been so well described in THE GARDEN (June 21, 1924, page 434). July is late for the Alps—for flower hunting, that is—unless you go very high: and Mont Louis is anything but high. And phew! it was hot. I liked the dull little town, compact within its fortifications, and unspoiled by modern improvement; and I liked the friendly, rather ramshackle hotel, with its casual, go-as-you-please way of seeming to run itself—and producing perfectly wonderful meals. The one really important thing about life at Mont Louis—apart from plant hunting—was how to avoid being taken for joy-rides by the hospitable *patron* of the hotel. It was a powerful, ugly, khaki brute of a car, and the *patron*, with a large staff of brothers, cousins and friends, seemed to spend all of every day tuning it up in the garage.

A little earlier—only a week or two—Mont Louis must be a Paradise of flowers. Now, in July, it was full haytime. Gentians, acaulis and verna were in ripe seed, and only a tattered narcissus remained here and there. I shall go again another year, in early or mid June. Yet I do not regret having visited Mont Louis in July. I found my Gentiana pyrenaica in good enough flower to see what a first-class beauty it is, and I found it, moreover, in seed. I think the best and briefest description I can give of the plant is to say that in habit and in flower it is like a dwarf compact edition of Gentiana sino-ornata, with flowers of an intensely brilliant violet purple. And it appears to revel in the same conditions as to soil and moisture. G. sino-ornata, I find, requires a soft rich soil of peat and leaf-mould, and likes a good deal of moisture. Gentiana pyrenaica I found growing in rather moist, heathy places, sometimes quite boggy, and the wetter the ground the more luxuriant the mats of the plant seemed to grow. The last afternoon I collected at Mont Louis, I came upon a wonderful swampy meadow, where Gentiana pyrenaica and G. verna grew in solid turves a foot across, among the coarse grasses, every plant thickly crowded with seed heads. It must have been a magnificent discord of pure blue and violet when in flower. So swampy was it that I squelched about with the water over the tops of my boots. But in other places G. pyrenaica was growing in far less boggy ground, though always the soil was of that rather peaty, spongy nature which never becomes very dry, and into which the rather soft, delicate roots delight to quest.

There seems to me to be a distinct relationship between Gentiana pyrenaica and the family of the ornata gentians—G. sino-ornata, G. Farreri, G. Veitchianum, etc. In habit and soft root system, they are very near, as also in soil requirements. In the ten-pointed corolla—five major and five minor intermediate points—there is a strong family likeness. But the most marked resemblance of all is in the carrying of the seeds. G. pyrenaica pushes up a slender column above the fading corolla, which widens at the summit into a flattened purse-like ovary. When ripe the ovary splits and opens flat and wide, with the seeds loosely attached to the two inner surfaces and fully exposed. A similar arrangement is common to all the ornata gentians.

Farrer states that G. pyrenaica is indifferent as to lime in the soil. He may be right, but I think probably he is not. Anyway, it is a local plant, and at Mont Louis it occurs solely on non-calcareous formation.

I spent a very jolly week wandering over the great moorland floor of the Mont Louis valley, exploring the pine forests about Font Romeau. One Sunday I pushed up into a rocky gorge in the mountains facing the town. This gorge, known as the "Asses Room," was a wild desolation of gigantic tumbled rocks and breast-high jungles of Rhododendron ferrugineum, Botanically, it was dreadfully dull. The only plant in which I could take a flicker of interest was a large-growing, white-flowered mossy saxifrage, possibly a form of S. geranioides. Entomologically it was rich—in gigantic ants and bloody-minded horse flies, which, however, found me more interesting than I them.

A very striking plant in the hayfields at Mont Louis was Geranium pratensis, for the form which is dominant there was unlike any pratensis I have ever seen. Instead of the typical violet-coloured flowers, they ranged through the loveliest lavender blue, clear and luminous, some a little paler than others, and one or two almost white.

Although true alpines were practically over—and it *is* disappointing to arrive in a rich alpine district a fortnight too late—my solitary wanderings were cheered wherever I went (except in the "Asses' Room") by the frequent little flares of Gentiana pyrenaica, blazing brilliant violet in the grass. It was for that that I had come, and I saw enough of it to astonish me that any alpine could be so much more brilliantly beautiful than the brilliant traditions that still lingered around its almost forgotten name. I found it, moreover, a good plant to collect and to establish. If I found it even more lovely than tradition had led me to expect, I also found it far less difficult to handle than tradition had led me to fear. After a short sharp dash to the Central Pyrenees to get ramondia, I hurried home with my gentians to give them every chance of survival. And Gentiana pyrenaica has rewarded my consideration. True, I have only possessed it a bare five months, but those months are the very ones in a collected plant's life which are the most dangerous. All my plants have not only survived, but have prospered amazingly.

First there is an immense turf of the plant, still with its native grasses, nearly a foot across, and looking as fit as can be;

Digitized by Google

also a dozen or so rather smaller tufts, also still growing with their native companions and likewise prospering. These live in pots and a large pan. For soil I made a confection, rich but light, of peat, leaf-soil and silver sand. Further, we potted up an immense number of smaller plants, teased out clean from all grasses. This plant, which had always had rather a murky reputation as a difficult brute to manage, has astonished me with the readiness with which it has taken to domestic life.

Having at last found a sure way of growing Gentiana sino-ornata, and applied the very marked relationship between it and G. pyrenaica, I begin to think that pyrenaica may respond to sino-ornata treatment, and prove a perfectly tractable garden plant, after all.

EARLY-FLOWERING RHODODENDRONS

BY R. L. HARROW (*Edinburgh Botanic Garden*)

AMONG the large number of rhododendrons now in cultivation several may be depended on to produce their flowers regularly from January to March; indeed, in a mild season, as the present one, they will commence to bloom in December.

The earliest to open its flowers here is R. parvifolium, a member of the Lapponicum series and a native of north-eastern Asia. The plant is not a large grower, generally about 2ft. or slightly more in height, with wiry stems and a rather scanty number of leaves at their apex. The flowers are of a rosy purple colour, freely produced in dense heads at the apex of their shoots forming a pretty bit of colour about the end of the year or beginning of January. Here it grows freely with but little attention, beyond an occasional top-dressing of leaf-soil and loam during winter. In sequence of flower this is followed by R. mucronulatum, a native of Korea belonging to the Dauricum series. This is almost a deciduous species, but it usually retains a few of its leaves at the tips of the branches among the flowers, which are generally single, from buds at the extremities of the shoots. The individual blooms are of a rosy purple colour, about an inch or slightly more in diameter; the calyx is slightly lobed with long ciliate hairs along the margins. The plants here are about 4ft. in height, though it is said to attain greater height, and are decidedly attractive when in full bloom. It will succeed in more sun than is required for evergreen rhododendrons, and thrives with the usual treatment given to the genus. Some years ago the Yokohama Nursery Company listed in their catalogue a very similar plant under the name of Azalea acuminata. It is probably a geographical form of R. mucronulatum, but is, for garden purposes, easily distinguished by its later flowering season—generally commencing in February, when the last named is finishing its flowering period. The flowers are also lighter in colour and the lobes of the calyx seem entirely absent. It forms larger bushes and the habit is more dense. In a favourable season this form is very showy with its mass of pinky coloured blooms. A note on the subject of early flowering rhododendrons would be incomplete without R. dauricum, upon which odd flowers may be found during most months of the year, but is usually in full bloom from the end of January onwards. Its flowers seem to be capable of withstanding more frost than is the case with most species, and are best seen with a glimpse of sun shining through the bed. Perhaps the most showy subject here at present is a hedge of R. præcox more than 50yds. long, and a mass of bloom. Grown in this way it shows itself to advantage and forms a popular sight in the garden.

LARGE WHITE FLOWERS OF RHODODENDRON MOUPINENSE FROM SZECHUAN.

RHODODENDRON PARVIFOLIUM, ONE OF THE EARLIEST TO FLOWER.

R. moupinense from the mountains of western Szechuan is a very hardy plant which will stand a considerable amount of wind if planted fairly closely together in a clump. In positions such as this it will take years to gain a height of 18ins., but in more sheltered positions and shaded places it is sometimes seen up to 30ins. or more. Here a clump grown in a raised part of the rock garden, a couple of yards in diameter, forms a dense canopy of foliage, and flowers well during February. The large white flowers are, unfortunately, too often caught by frosts, but a week of mild weather at the time of flowering will well repay its inclusion in any collection. Wilson states that in its native habitat it is epiphytic on oaks and other broad-leaved trees, but in cultivation requires no very special treatment of this kind.

R. scabrifolium, a native of Yunnan, a white-flowered species, is at present just showing flower out of doors. It is of rather tender constitution, and is apt to be cut back by severe frosts, though for the last two winters it has escaped any serious injury. The habit of this plant is rather loose and is best planted rather closely together. The scabrifolium series is a small one and includes R. spinuliferum, a species with narrow tubular red flowers too tender for out of door gardening in Edinburgh but which is flowering under glass now.

Among the earliest of the triflorum series is R. Keiskei. In Japan, its native habitat, this is said to grow from 4ft. to 5ft. high, but is not usually seen so tall in Britain. The flowers are of a pleasing yellow colour, and produced in abundance. It forms a neat bush-like habit and, like many Japanese plants, stands exposure better than many, and should be welcomed by all who appreciate an early display of colour in their gardens when flowers are scarce.

RIDEAU HALL GARDENS

BY GEORGE SIMPSON.

OUR READERS MAY BE INTERESTED TO SEE HOW SUCCESSFULLY ROCK GARDENING IS CARRIED ON AT GOVERNMENT HOUSE, OTTAWA, WHERE CONDITIONS COULD HARDLY BE CALLED PROPITIOUS.

THE gardens at Rideau Hall, the official residence of the Governor-General at Ottawa, make an appeal to the interest of readers from the fact that they are for the time being in charge of a distinguished British amateur gardener, Her Excellency the Lady Byng of Vimy. Combining, with the graces of social leadership and a talent for letters, a love of nature and a keen interest in gardening, Her Excellency is singularly well equipped not only to dispense the hospitalities of the Government House but also to direct the work of those who have to do with the embellishment of the grounds. To this task she has brought a practical knowledge and enthusiasm altogether natural to the Englishwoman but comparatively rare among Canadian women with similar responsibilities and preoccupations.

LOOKING ACROSS THE LAWN AT THE REAR OF GOVERNMENT HOUSE.

A BORDER OF HARDY PERENNIALS WITH A BACKGROUND OF ELMS.

Previously to her coming it was only to a few that Her Excellency was known as an amateur gardener, and these awaited her arrival with confidence and hope. They had read (THE GARDEN, 1921, page 314) or heard of what she had done for the rehabilitation of the estate of Thorpe Hall, and they were prepared to pay homage to her as an exponent of all that is desirable in the gentle art of gardening. The expectations of these ardent spirits, horticulturally speaking, have been more than realised. Her Excellency has not only busied herself with the gardens at Rideau Hall but has done much to stimulate interest in gardening throughout the Dominion of Canada, and has proved a generous and practical friend to organised amateur horticulture.

In this she is but following tradition. As far back as the middle of last century Mrs. Thomas McKay, the then mistress of the Hall, was a patron of the local horticultural society and an exhibitor at the shows held at that time on Barrack Hill, now the site of the Parliament Buildings. With the transfer of the estate, comprising some 87 acres, to the Dominion Government at the time of the confederation of the Canadian provinces, the gardens at Rideau Hall came under the direction of successive governors, and each left his impress upon them—or probably it would be more correct to say that the wife of the Governor-General was the directing spirit.

Among the predecessors of Her Excellency, none took greater interest in the beautification of Rideau Hall grounds than Lady Grey. The Duke and Duchess of Devonshire also devoted much attention to the gardens and a hedge enclosed garden begun by Her Grace the Duchess is now in course of development. A tangible memorial of the interest taken by the Devonshires in matters horticultural is the Devonshire Cup given to the Ottawa Horticultural Society for annual competition.

Before the coming of Lady Byng there were in Canada—outside of British Columbia—few examples of rock gardening. Mr. Morgan of Montreal had demonstrated the adaptability of this sort of garden to the climatic conditions of eastern Canada by an elaborate example at Senneville on the St. Lawrence, but the cult had made little progress. One of Her Excellency's first undertakings was the planning and construction of a rock garden on a somewhat ambitious scale. She found ready to her hand, if not the ideal site, at least a fairly good one—on the slope where contact is made between the more naturalistic and dressed parts of the grounds. The background was there too, provided by a screen of established maples and elms, sufficiently near to protect and yet sufficiently remote not to menace the well-being of the plants that were to be set in the pockets amid the stones. But the measure of her good fortune was heaped to overflowing by finding strewn about the glades of Rockcliffe—adjoining Government House grounds—an abundance of limestone, weather-worn, fissured and fractured by the elements. Her Excellency's carefully prepared plan was put into the competent hands of Mr. Harris, the head-gardener, who had received his training in Scotland; and the result is seen—or, perhaps, only suggested, because it is not fully disclosed—in the accompanying pictures. The illustrations do only partial justice to the original, in that the photographs were taken in the heat of midsummer after the early bloom had passed. Some initial planting had been done to furnish the garden until the permanent plants had attained size and these temporary denizens, since removed, had exceeded their allotted limits and attained a stature not to be tolerated in the rock garden.

The planting is extensive and varied and its survival after two Canadian winters proves its climatic suitability. The fact is that many plants accustomed to the frosts and snows of high altitudes endure the dry, cold winter conditions

Digitized by Google

of eastern Canada better than the humid atmosphere of more temperate regions. The list of plants includes such hardy things as æthionema, Anemones Pulsatilla and sylvestris, aubrietia, campanulas in variety (exceptionally well suited to Canadian conditions) dianthi in variety, the gentians, Alyssum saxatile, dwarf irises, both rhizomatous and bulbous, dwarf phloxes in variety, primula species, polyanthus and primroses, saxifrages (encrusted and mossy), the lesser spring bulbs in variety, narcissi, Iberis sempervirens, arabis, Saponaria occymoides, sedums, semper vivums, a few suitably placed specimens of the dwarf coniteræ, and many others.

This garden is a novelty to many visitors to Government House and excites much interest and admiration.

The general garden scheme includes formal bedding, perennial borders, plantings of annual flowers, vine-covered pergolas and retreats, woodland walks and beautiful vistas. Scattered about the grounds are some century-old specimens of the native elm.

THE EXTENSIVE ROCK GARDEN AT RIDEAU HALL WHICH HAS AN IDEAL SITUATION IN THE MIDST OF NATURAL SURROUNDINGS. It is populated by a varied collection of rock plants which appear to thrive exceedingly well in the cold conditions of Eastern Canada.

CORNUS MAS

THE Dogwoods as a whole are an interesting group comprising many hardy ornamental shrubs with handsome foliage. Despite also their brilliant autumn colouring and their attractive flowers and fruits they are little grown in the majority of gardens. Why that should be is difficult to guess, as they are very desirable either for growing as isolated specimens or for planting in shrubberies. They are of easy cultivation, while a large number of them are propagated from seed without difficulty. One species, Cornus Mas, the so-called Cornelian Cherry, especially, appears to have fallen in public estimation judging from its rare occurrence, and several of our readers have been complaining of its rarity. Years ago this was one of the most popular of all early-flowering shrubs, and through no fault of its own this popularity seems to have disappeared. Our illustration shows a typical specimen in full flower with its tiny yellow blossom covering the leafless twigs. The fruit is also attractive, being a fiery red, but owing to the change of climate it does not appear to fruit so freely as in the past. Practically every reference to this plant prior to 1880 speaks of its fruiting qualities, but possibly in those days the weather was more to its liking. The flavour of the fruit is fresh and acid, and it is said that in former times it was used in the place of fresh green almonds in dessert.

THE CORNELIAN CHERRY, CORNUS MAS.

The Cornel tree is a native of Europe, and the name of Cornus Mas was given to it by Linnæus. It has long been in cultivation in England, and apparently used to be planted around old religious buildings. It is very easy to cultivate successfully, and thrives best in good loam with a certain amount of moisture. Like many of these early-flowering trees and shrubs with small flowers, it should be planted where the afternoon sun strikes it against a dark background which shows up the flowers to best advantage. In a suitable situation it attains a height of 15ft. to 20ft. There were a number of varieties other than the type in cultivation in the middle of last century, but many of them appear to have died out.

It is a great pity that such a valuable decorative shrub for this dull time of year should have disappeared so much from ken. There is a fine specimen at Kew which is always much admired, but it is far from common in private gardens. It is to be hoped that this plant will regain its popularity, for it is worthy of it.

THE CONSTRUCTION of a LAWN TENNIS COURT

BY REGINALD BEALE.

THIS ARTICLE, FULL OF TIMELY HINTS ON THE MAKING OF A GRASS COURT, SHOULD PROVE OF INTEREST AND VALUE TO OUR MANY READERS WHO ARE PLAYERS OF ONE OF THE MOST POPULAR OF GAMES.

THE measurements of a grass court are 78ft. by 36ft., but in order to obtain adequate room for fast play an area of 120ft. by 60ft. is required. This allows a run back of 21ft., with 12ft. to spare on the side lines. If possible, arrange the court to run north and south in order to avoid as much as possible playing into the rising and setting sun. North-north-west and south-south-east is the orientation of the championship courts at the New Wimbledon ground. Should the ground fall away in the length or width of the court it will be necessary to level the site and the most economical method to employ is to take the soil from the high end and use it to raise the lower end. The fall of the ground can easily be ascertained by means of a series of pegs, a straight edge and spirit level. If a peg is placed in the highest point protruding say, 6ins. from the surface, in order to clear obstructions and the one at the lower point is 6ft. 6ins. above the existing level, it is obvious that the ground will have to be excavated at the high end to a depth of 3ft., and made up 3ft. at the lower end. Should the ground fall both ways it will be necessary to take cross levels. When the levels are got out, it is a simple matter for any gardener to work to them. When a serious alteration has to be made in the level, both the length and width of the court should be extended by 6ft. or more, as one cannot run freely and with confidence, and at the same time watch the ball, if there is any chance of falling headlong down a steep bank.

When everything is set out, remove the existing turf and lay it aside, if it is good enough to replace, but if it is not, stack it in a convenient place to rot, so that it can be used for making compost. Then remove the top spit soil and place it aside. This is most important, particularly if the surface soil is thin and the sub-soil poor gravel, clay or other inferior soil. Should the surface soil be lost or badly mixed with undesirable sub-soil, it will be more difficult and costly to get satisfactory results. The next operation is to level out the site with the sub-soil by wheeling it from the high end and dumping it on the lower. This must be done with the utmost care, and the subsoil spread evenly in thin layers, and well trodden into position, otherwise it will slowly but surely settle and spoil the level of the playing surface.

The next step is to examine the soil and subsoil in order to determine what drainage, if any, is necessary. Should the soil be of a porous nature it will not be necessary to make any provision for drainage, but should it be of a retentive or clayey nature, or should the site be obviously wet, the problem must be given very careful thought. It is difficult to lay down any hard and fast rules as circumstances differ so widely, but it should not be difficult for the man on the spot to determine the amount of drainage necessary and adapt a system likely to prove satisfactory. When a court has been levelled in the way described, the excavated end is always the wettest on account of the surface water running from the hill and oozing out of the banks. It is therefore wise in all cases to cut two trenches at the foot of the banks, making them 12ins. deep at the corner where they meet and 18ins. to 24ins. at the ends, where they discharge. Then, if necessary, cut a trench diagonally across the court, allowing the same fall as given above. Lay 3in. pipes in all the drains and fill up with clean cinders. This should effectively deal with the wet, cut-out end, but if it does not, additional spurs can be added.

When coping with heavy, impervious clays it is imperative in addition to the drains to spread a layer of clean ashes from 3ins. to 6ins. deep over the whole site. Level sites should be drained on the herringbone principle, with a 4in. drain down the centre and 3in. spurs, 12ft., 15ft. or 20ft. apart, according to circumstances; but if the site is likely to be wet it will be better in the long run to excavate it 12ins. deep, put in a moderate system of, say, a 4in. main drain down the centre, and 3in. spurs 20ft. to 30ft. apart and cover with a 3in. to 6in. layer of ashes.

Provision for at least 6ins. of top spit soil must be made, and as all classes of soil, sand, gravels, chalk, loam or clay will be met with, and in most cases the soil, no matter what it happens to be, will have to be taken as it is found, it is again only too evident that I must write in general terms. The ideal soil is a good fibrous loam that will carry a fine, strong, hard-wearing turf and roll down to a firm, true surface that will not break up or crumble under foot. If the soil does not answer to this description and suitable soil can be obtained locally and a first-class court is desired, sufficient soil should be purchased to form a layer over the entire site from 2ins. to 6ins. deep. Should it be decided to finish off in part or whole with such soil, allowance must be made for discarding a similar quantity of the natural soil, otherwise the surface of the court will be raised proportionately by the amount used.

In most cases, however, the cost of the soil and transport will effectively bar its use, so I will now endeavour to explain how the natural soil should be worked up. First of all, test it for lime and if there is a deficiency, make it good by adding half a ton to a full-sized court; then spread the soil evenly over the surface or dig it over as the case may be. Manure should now be spread using ten loads of well rotted dung or fresh peat moss manure. If this cannot be obtained, substitute with 2 cwts. of Carter's Complete Grass Fertiliser. If the soil is of a retentive or clayey nature it should be broken up well and thoroughly mixed with fine cinders, such as will pass through a ¼in. square mesh sieve, using 3 cubic yds. or more to every 100 sq. yds. of surface. The object of using cinders is to open up heavy or clay soils and so improve the surface drainage, warm the soil and allow the roots of the grass to travel through it freely. In fact it is a waste of money to put in a cinder foundation unless the surface soil is sufficiently porous to allow the rain to go straight through it and not remain on the surface, as it will if it is impervious or nearly so to water. Every load used in the construction of the court should be spread evenly and well trodden into position. Breeze or cinders, if used, should be thoroughly mixed with the soil, right the way through, and all manure incorporated with the surface soil, and none of it buried deeper than 3ins.

If the work has been done properly the surface should be quite level, with the same depth and quality of soil throughout. The actual levelling of the surface depends upon the skill of the men employed. Some can make a good job with very few pegs, but in order to avoid error, it is just as well to drive in a series, say, 6ft. apart, and true the soil up to them by means of a straight edge. This operation must naturally be done with care, and all inequalities corrected by adding or removing soil and repeatedly raking, treading, and rolling until the surface is quite firm and true and when walked upon hardly shows a mark.

The lawn is now ready for turfing or sowing as the case may be. If expense is no object and time a consideration, turf is undoubtedly the best, provided that only a good quality is used; the lawn can be played upon with certainty the following season. It is not easy to find good turf and unless one goes to the expense of purchasing Cumberland and other Marsh turf and even this, unfortunately, is full of weeds, or has the luck to find good stuff locally, there is no alternative but to use meadow turf and work it up.

Should, however, expense stand in the way or the lawn not be required for use the first year, seed should be used. The reason why it takes longer to produce a lawn from seed than it does from turf is fairly obvious. Turf is naturally old and must be fairly fibrous with a strong root mat to stand lifting, and as it is the matted root growth rather than the leaves that have to stand the wear and tear of the game, it will surely resist better than turf produced from seed, unless the latter is given time in which to develop and form the strong matted root growth desired. It does not matter a scrap which is used so far as weeds are concerned, as it is just as economically impossible to buy turf free from weeds as it is to destroy the weed seeds in the soil. If seeds are used, sow them at the rate of from 1 oz. to 2 oz. to the square yard, cover by raking the surface in two directions and finish off with a light roller.

To get the best results from turf it should be cut 12ins. by 12ins. by 2ins., and, if possible, trimmed in a gauge box to

Digitized by Google

a thickness of 1½ins. If this is done it can be laid on a firm, true surface with dead accuracy without packing; when it is cut 3ft. by 12ins. by 1½ins. and rolled, it will require very careful packing, if anything approaching a level finish is to be obtained. The turf should be laid diagonally across the lawn, after slightly disturbing the surface to a depth not exceeding a quarter of an inch. Place the turf carefully into position, pack if necessary with sifted soil and gently beat it down with a turf mallet.

The conditioning and upkeep of lawns has been explained in another article and with greater detail, and as I have come to the end of my space I must leave it at that.

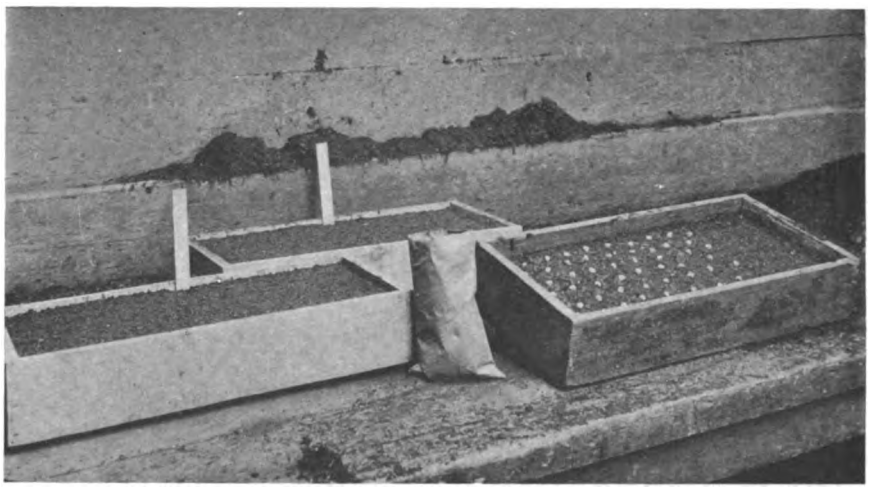
SUCCESS WITH GARDEN PEAS

BY EDWIN BECKETT.

THERE are two classes of growers of peas with whom I disagree; the first, the person who will persist in growing those old and, as I contend, worthless sorts in comparison with modern varieties of value, and the other, the man who says he cannot afford the space to grow many peas, as they are not a profitable crop to grow.

Now let us consider the first proposition, *i.e.*, the nearly worthless sorts. I wrote on this point, in a book on vegetable growing, nearly twenty years ago, and then proclaimed against the use of such a variety as the "Gladstone" pea, uncertain in its habits, comparatively poor in its quality, and yet people would grow it, and neglect such a fine type as the "Duke of Albany." Why was it? I really believe it was because, when it was successful, it was a pretty stiff little green pod, whose appearance was certainly better than its edible qualities. Let me once again entreat those who are sticking to old, out-of-date sorts, to leave them out of the seed order and employ the modern, better quality varieties; I will warrant they do not return to the older sorts.

Next, the man who has not the space. Here again I fancy is one who will not move with the times, for I have often seen a row of peas in a cottage garden, properly grown, and of a good modern sort, that was more than worth the strip of ground they were occupying, and as "man cannot live by bread alone," so one likes to adapt that Biblical quotation to vegetable food, and have a change of diet from the inevitable potato, cabbage, onion, etc., and what more delicious change can one wish for than a good dish of fine flavoured modern garden peas. There is also an important economic fact that must not be overlooked, for peas, requiring proper cultural methods applied to their growing, are a crop that greatly benefits the ground, owing to the soil preparation that should be accorded them.



THE RAISING OF PEAS IN BOXES.
These should be plunged under a south wall after sowing.

AN EXCELLENT CROP OF WELL FILLED PODS.
Note how the staking is carried out.

Having got these two points dealt with, we will consider shortly what may be the best ways to raise fine peas. Firstly it can be recorded, that, where facilities exist, it is possible to have good culinary peas from May until the frosts cut the vines, say at the end of October. The very early supplies can only be raised under glass, in such a place as a cool house, such as that devoted to the growing of trained fruit trees, and it may also be carried out in pits and frames, raising dwarf, medium or tall varieties of suitable character, according to the receptacle. They may be raised in either pots, boxes or in the borders of the house. For the very early crops sow in a compost of good fibrous loam, well decayed leaf soil, and some well spent manure such as comes from an exhausted mushroom bed, adding to each bushel of this mixture a 6in. potful of bone meal. Use pots of 8in. to 10in. diameter, well provided with drainage, and do not more than half fill with the soil mixture, as moulding up with this should take place after the plants have passed the top of the pots. Select the seed carefully so as to use only the best, and sow ten to a pot, covering them with about ½in. of the finest of the compost, watering well in. Place them in a cold house or frame to germinate, for fire heat is not required, and the plants once through should have all the light and air possible. Stake when about 3ins. tall, and remove half the plants, as five will be sufficient to a pot. Once sufficient flower has opened—do not strain the vine too much—you can pinch out the point and remove all side growths. Feed liberally with liquid manure after the pods have set.

Continue the same process with another batch sown in January, which can later be stood out of doors to grow in a sheltered spot facing southwards.

So much for the crops that mainly rely on glass for early production. Now for a consideration of those growing outside. First comes the ground preparation, an operation which I consider to be the main item for the production of really good peas with heavy cropping. The prime essential is deep trenching, 3ft. down; place a good layer of farmyard manure at the bottom, and again in the middle of the trenched portion. For the first and second early crops I

Digitized by Google

always advocate sowing under glass, as against the old method of autumn sowing. Sow in boxes, placing the seed about 2ins. apart, and using a compost like that previously noted. A sowing in January, two in February, two in March, and another in April, will keep up a fine succession, and at the time of the last named, the first sowing in the open can be made, and by continuing these about every ten days to a fortnight, in sufficient quantity, the supply can be kept up to the late autumn. A word as to sowing is necessary. Too frequently is this done too thickly, only twice the number of seeds should be sown as there are plants required; these should be thinned out when young, leaving the plants from 6ins. to 10ins. apart according to the height of the final growth. Sow in double rows, and allow plenty of space between any pair of such rows, for the space between can be well utilised for other crops. Plants raised in boxes should be planted out on the same lines, and all should be staked when the plants are quite young. Staking is most necessary and is a very important point in growing peas. Good brushy hazel sticks are the ideal, and the spaces at the base should be filled in with the twigs clipped from the tops. The height of the sticks must, of course, be according to the height of the variety grown, and should be even a little above the average height of the mature plant.

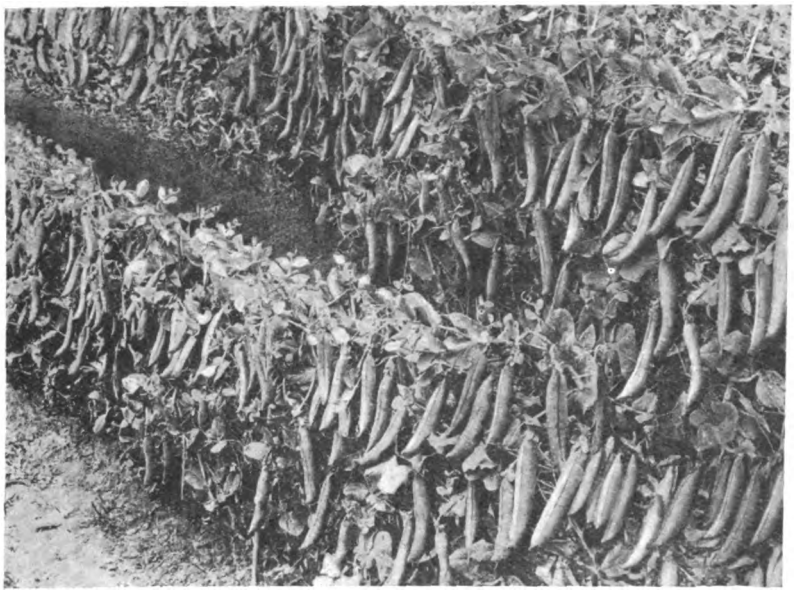
Slugs may be troublesome, and therefore an encircling guard of sharp cinder ash should be added, if available, to protect the young plants from the marauders. Plenty of water, and feeding with manure water when the pods have set is beneficial, and for a change from the latter an occasional sprinkling of a reliable fertiliser is most helpful, while during hot, dry spells, syringing in the evening is desirable.

For late crops, it is well to prepare trenches, say 2ft. deep, breaking up the bottom of these well with a fork, and laying on top about 9ins. of cow manure, filling up with a good loam, leaf and horse manure compost. This method, on poor light soils, when employed for mid-season crops, will be a profitable move, especially as the trench permits proper and successful watering when necessary.

I want for a moment again to refer to the great advisability of trenching properly in ground preparation for peas. One has only to see two rows of peas, the one on trenched and manured ground, and the other on ground merely dug over, to realise the real worth of the proper methods, for the crops are not to be compared. The whole secret is the depth to which the roots of peas will dive after their food and moisture, so do not hesitate, but break right down into the soil for this crop.

Early and late crops will be benefited if the points are pinched out when sufficient pods are set.

[In connection with the above article and the procuring of up-to-date varieties, we have pleasure in bringing to the notice of our readers who may not have been fortunate enough to obtain the catalogue of Messrs. James Carter and Co., a striking novelty in the vegetable world which has just been raised by them. This is their new giant-podded dwarf pea, well named "Giant Stride," of which an illustration is here reproduced. It is claimed that this is the largest podded dwarf pea in the world, and it maintains all the good qualities of its predecessors. The haulm is strong and produces an abundant crop of its large pods which are generally perfectly filled with large, luscious peas of good flavour. Its ideal height of only 2ft. and its robust constitution should go far to make it one of the best peas in the market for everyday use. It may be mentioned that Messrs. Carters are now despatching seeds, and it is probable that the demand may exceed the supply. The price asked is a reasonable one and is within the reach of all.—ED.]



ONE OF THIS YEAR'S NOVELTIES IN GARDEN PEAS, "GIANT STRIDE."
It bears abundant crops of large and well-filled pods, and is an ideal height.

BOOKS ABOUT PLANTS—IV

TECHNICAL AND SEMI-TECHNICAL.

I HAVE been asked by the Editor to write this article in the hope that it may assist those who are keen book lovers and collectors in the formation of a library of botanical books be they so inclined. The studies of botany and horticulture are closely associated, and, indeed, it is difficult to draw a definite line of demarcation between where the one ends and the other begins. Botany is generally defined as the scientific study of plant life, involving nowadays many branches devoted to different aspects of the plant. For example, we have plant geography, plant physiology, ecology, fossil botany and so on, and it will be readily seen how difficult it becomes to advise one what books to purchase which will serve as an elementary course of instruction and at the same time prove valuable in after years as works of reference. A library, when all is said and done, is a collection of books on subjects on which the owner is keen. They may be picked up at random or they may be obtained in series with a definite purpose in view. To the horticulturist, then, who commences to take a passing interest in botanical study, the first book I would recommend is a general elementary text book. Of this type of book there are several which can be obtained—some written at length in the form of a story; others, again, bristling with nothing but hard facts. Then comes the choice of the individual. Each must choose according to his type of mind. To those who appreciate good solid fact without unnecessary padding, there is no better book on elementary botany than Louson's Text Book. It is packed with useful information from beginning to end. The fundamentals of the subject are clearly and concisely stated. The book abounds in definitions and the subject is very skilfully treated, the reader being presented with a true conception of the wide confines of his subject. A new edition was published about two years ago, including a chapter on genetics—dealing with evolution, variation and kindred questions. To those whose minds can grasp essentials better when woven into the form of a pleasing story, I recommend Bower's "Botany of the Living Plant," published by the Macmillan Co. There is probably no botanist more qualified to write on the subject than Professor Bower of Glasgow, and he does so in a most charming and delightful style. This volume may be said to be a simplified edition brought up to date of Strasburger's "Text Book of Botany," which has come to be looked upon as the standard work on elementary botany.

Digitized by Google

After a simple botany has been mastered, the reader will probably have made his choice as to the branch of the subject on which he would like further information. It may be that the physiological side appeals to him, or perhaps the ecological. Be it the former, then a simple physiology on the lines of that published in the Cambridge Biological Series would suit his purpose admirably; or, if the latter, then he would derive extreme satisfaction from Tansley's "Elements of Plant Ecology." But just here a word of warning will not come amiss. If the student be ecologically inclined, then I think it is wise that he should become thoroughly familiar with his native plants before he commences to study them in relation to their environment. Bentham and Hooker's "Flora of Great Britain" when used in conjunction with the volume of illustrations will be found to be two of the most valuable books in a botanist's collection. They are published by Lovell Reeve and Co. Once a working knowledge of the native flora has been acquired, then ecology can be turned to in earnest. If it be the owner's intention to take up the study of systematic botany, one of the most useful books will be Warming's "Systematic Botany," published by Sonnenschien. This volume deals chiefly with the systematic classification of the flowering plants, although a discussion on the systematic position of the lower groups is taken up. A useful review of the lower groups treated from an evolutionary standpoint will be found in "The Origin of a Land Flora," by Professor F. O. Bower, published by Macmillan and Co. A most interesting conception of how the first land plants—in fact, if the truth were known, the beginnings of life—originated is presented in its pages, and the reader gets that feeling so well expressed by Wordsworth in these few lines:

> Hence in a season of calm weather,
> How inland far we be.
> Our souls catch sight of that immortal sea
> Which brought us hither.

Another volume written by the same author was published only two years ago on the Ferns (Filicales) by the Cambridge University Press. A second and companion volume to this is likely to be published shortly. A really delightful and readable book on the history of the fern, bringing in all the facts which have had a definite bearing on their evolution, leading us to form a true perspective of the group in the light of form and function as outwardly expressed by these plants at the present day.

Another branch of the subject which during recent years is becoming increasingly more important is that of plant disease. It is strange that works dealing with this aspect of botanical science are remarkably few. It is true there are a number of German works on the subject, but these are only of service from a reference point of view. They deal chiefly with the classification of the fungi. A book which all gardeners will find useful is a "Text Book of Plant Disease," by George Massee, published by Duckworth and Co. It is somewhat out of date, and inaccurate in parts in the light of recent knowledge and research, but nevertheless is worth having on a library shelf. A little book which will be found of service is that on the "Diseases of Field and Garden Crops," by Worthington E. Smith, published by Macmillan and Co. It is long out of date, but the beginner will find it of interest. A more recent volume on "Plant Disease," by Bennet, also published by Macmillan, appeared last year. It is somewhat limited in its scope, but presents all the main facts in a condensed form. Technical books on the fungi fall to be mentioned, one on the "British Rust Fungi," by Grove. This is a standard work and now by no means complete. The second is "The Fungi," by Dame Helen Gwynne Vaughan, published by Cambridge University Press. This deals with the group from a more or less cytological point of view and is certainly not recommended for the beginner.

It may not seem within my province when dealing with botanical works to mention two volumes which deal with soils and their treatment. But since the soil is inevitably bound up with plant growth, it is wise, I think, to have these two on the bookshelf. The first is "The Soil," by Sir A. D. Hall, published by John Murray; while the second is "Fertilisers and Manures," by the same author and publisher. These give a clear presentation of the constituents and properties of the soil, of the main classes of manures and their action in improving the fertility of the soil and on the crop. The why and the wherefore of manuring is given in the most simple way, so that the two volumes are understandable by the most uninitiated. They are really invaluable volumes.

For those who imagine that a scientific botany is beyond their powers of comprehension, I would like to mention two volumes which I feel sure they would find interesting as well as instructive. These are, one, a recently published volume called the "Wonder Book of Plant Life," by Fabre (the famous French naturalist) (T. Fisher Unwin), the other being "The Life of the Plant," by A. C. Timeriazeff (Longmans and Co.). The salient and fundamental facts are presented in a way that does not give the reader indigestion but which rather tends to whet his appetite. In this more popular connection I would like to bring to the notice of readers two small volumes on plants in the Home University Library Series, published by Messrs. Williams and Norgate. One is "Plant Life," by Professor Bretland Farmer, while the other is the "Evolution of Plants," by Dr. D. H. Scott. These are excellent little books. Another small book which is worth purchasing is "Plant Geography," by Boulger, published by Dent and Sons at about 1s. 6d., I think. It presents the main facts of plant distribution and the underlying reasons in a nutshell.

A recent volume published by Messrs. Sidgwick and Jackson on "The Biology of Flowering Plants," by Dr. Macgregor Skene, is one which every botanist should find of intense interest, especially those who are physiologically inclined. Anyone interested in plants will find the book instructive yet pleasing. The life of the flowering plant is presented in a most fascinating manner.

One thing more. There are many monographs on different aspects of the subject which are published from time to time by Longmans and Co., such as "The Soil in Relation to Plant growth," by Dr. Russell. These contain an account of the latest work in that particular branch, and in many cases are worth acquiring. There are other volumes, such as Schimper's "Plant Geography," Pfeffer's "Physiology of Plants," Goebel's "Organography," De Bary's "Comparative Anatomy," Coulter and Chamberlain's "Morphology," which will be of the greatest service as reference books. These, however, can be consulted at any botanical library.

There are many more which ought to be mentioned, but I must confine myself to the limits of a short article, otherwise I will have the Editor saying a few words about botanists and their books.

G. C. T.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this*. It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

PLEASE REMEMBER TO MENTION "THE GARDEN" WHEN ANSWERING ADVERTISEMENTS.

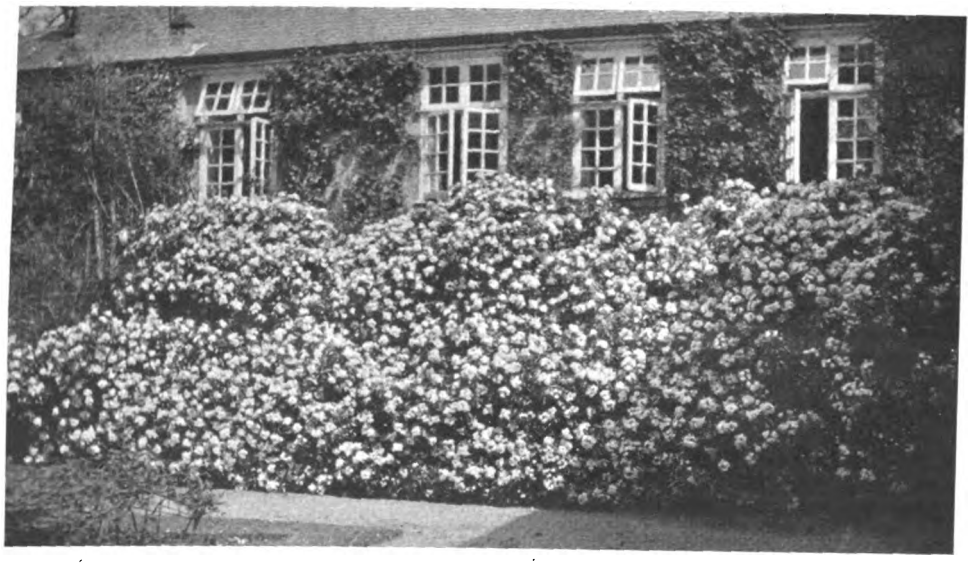
NOTES FROM CONTRIBUTORS

ONIONS: SOME OLD PROBLEMS.

IT is generally agreed that the season of 1924, with its abundant rainfall, was one of the worst on record for the ripening of onions out of doors, but it was also a year when the ravage of the onion fly was least experienced. Although, however, we were not troubled so much with this old pest as in a dry time, we were faced with an equally bad enemy in smut disease. As a grower of some years standing, I have come to the conclusion that it matters little whether plants are autumn raised, January sown in heat, or sown in spring out of doors in the orthodox fashion, there is no certain immunity from attacks of fly. I have seen it asserted that onions sown out of doors in August, allowed to winter there and transplanted in March or April, are "too tough in foliage for the onslaught of the fly." If that were so, we should, I submit, see more autumn sown onions, but unfortunately it is not borne out in actual experience, as although the damage done by the fly is less than among heat raised and spring sown plants, a bed of autumn raised onions is not absolutely free from attack. The opinion of other growers in regard to last season, coincides with mine, *i.e.*, fly was not so troublesome though smut disease presented itself. As is known, the latter is an insidious disease which forms on the outer skin of the bulb, a sooty grey substance which soon spreads. It would almost appear that while in a wet season the fly is less rampant, requiring warm and genial weather for its work of destruction, it is favourable to smut disease, which in effect is mildew. The fly and smut have dogged the onion grower always, and, as far as my experience is concerned, there is no reliable remedy. Certain methods employed do in a measure render the access of the fly to a bed more difficult. One—perhaps the oldest of all—is the free use of soot during May and June when the pest is busy depositing its eggs between the leaves, shortly after which, maggots appear and the plant is eaten away. Soot is best dusted at night or early morning while the dew is present. Another alleged preventive is paraffin, poured in vessels, and distributed over the bed. It is said that the fumes are so obnoxious to the fly that attack is impossible. The strength of the liquid, however wanes when exposed to the air for long, and it needs to be renewed. I have tried this, but cannot say that it was efficacious. Of the two, soot has proved the best standby. Once onion plants are seen to be affected, and the first symptoms are drooping of leaves and further examination usually reveals the small maggots in the young bulb, there is no half measure to be employed. Nothing less than rooting out plants and soil and burning both, is worth considering, and most onion growers are in accord as to the wisdom of this. Here is a question which was put to me the other day: "Is it possible for the larva of the onion fly to lie dormant in the soil from one year to another and then awaken to activity?" In common parlance, "Where do flies go to in the winter?" Can someone elucidate the mystery please?—CLAREMONT.

CHOISYA TERNATA.

READERS of THE GARDEN may be interested in the accompanying illustration of Choisya ternata which is growing here. It is not, as it perhaps appears to be, against the house, but on a brick wall some distance away. It is in a very sheltered corner and has always done well. The bushes became so large and straggly and encroached on the path so much we have now had to cut it very drastically.—MAUD STEVENSON, *Stoke Poges.*



EXCEEDINGLY FINE BUSHES OF CHOISYA TERNATA AT STOKE POGES.

NOTES ON BORDER PLANTS.

ACHILLEA MILLEFOLIUM ROSEUM.—This yarrow has been long in cultivation, and therefore we may look upon it as an old-fashioned plant. Its charming colour—a rosy red—and its long flowering period give material for comment, as plants were in flower in August and even at the end of November two fairly large plants had each several clean and good coloured flower-heads borne on stems quite a suitable length for cutting. The plants, too, were well furnished with fine dark green fern-like foliage.

CHEIRANTHUS ALLIONII.—The plants raised from seed sown in July of the previous year flowered splendidly in the month of May last year. After the blooms faded the old spikes were cut away so that the plants would not become exhausted in seed production, and also that further flowering would be encouraged. This object was attained, as, although the plants did not effect such a display as in May, at the end of November this Siberian wallflower upheld a few dainty orange-coloured flowers.

CHRYSANTHEMUMS.—November is certainly well named the month of 'mums. Of course, that definition applies particularly to plants flowering under glass. Yet large numbers of flower-lovers must have been charmed last season with the fine and prolonged displays borne by plants out of doors. On November 16th last, I observed in a villa garden several fine plants upholding good heads of white flowers, while a week later I again noticed some white-flowered plants making a brave show close by the door of a dwelling. Yet here, at the end of November, we had fine healthy plants of a variety called Pembroke bearing many wine-coloured flowers. Not only is this a dark-flowered chrysanthemum, but its foliage is strong, healthy and of a very dark green shade.

SCABIOSA CAUCASICA.—All who delight in soft shades of blue flowers will do well to grow the Caucasican scabious, or blue bonnet. Not only is it an ideal plant from which cut flowers can be obtained over a very long period, but the plant is almost a continuous bloomer, seldom being without flowers. Our plants bloomed quite early last year, then again throughout the summer and autumn, and even in November were bearing fine handsome blooms—some of them 3ins. in diameter. In one up-to-date hardy plant catalogue Scabiosa caucasica is described as "One of the jewels of hardy plants."—DAVID ARMSTRONG, *Midlothian.*

TWO FINE WINTER-FLOWERING HEATHS.

DURING the dull months of the year Erica carnea and E. Darleyensis produce a fine display of bloom, and they ought to be represented in every garden. E. carnea is a native of the Alps of Central Europe, and attains a height of 6ins. to 10ins. The flowers are rosy red, and when seen in a large bed it is very effective. Here at Castleford, Chepstow, it is associated with the hybrid Rhododendron Early Gem, and it is a beautiful combination, especially when the weather is favourable for the latter to open its flowers. Some years the blooms of the rhododendron are ruined with wind and frosts, but the erica always gives a good account of itself. E. Darleyensis is also known as E. mediterranea hybrida, it being a hybrid between mediterranea and carnea. It first appeared in the nursery of Messrs. J. Smith and Sons, Darley Dale, and grows about twice the height of E. carnea. The colour of the flowers is somewhat similar to E. carnea, but in a bed the general effect is quite distinct. Our plants begin to bloom in November, and during February they were a fine sight. A valuable attribute is the length of time these heaths remain in full beauty. Most, if not all, of the heaths should be planted in large masses or beds, and I find the two plants mentioned will succeed in ordinary soil in this district with the addition of very little peat. When the plants are past their best the old flower-stems should be removed, and then further pruning is rarely needed.—T. W. B., *Chepstow.*

PROTECTING CROCUSES FROM BIRDS.

IN many gardens, especially near towns, crocuses suffer badly from the attacks of birds. I have found that a very excellent way of protecting the flowers is to stretch lengths of cotton round about and even over the clumps. The cotton, which may be black or brown, is attached to short sticks, painted green to make them less conspicuous. Birds of all kinds have a perfect horror of any fine threads like cotton and, after one attempt to get at the crocuses, they are not likely to repeat the attack.—S. LEONARD BASTIN.

AN AMATEUR GARDENERS' SOCIETY

FOLLOWING on my note last week on the Amateur Flower Show to be held by the R.H.S., a little booklet has just been sent to me from the New Barnet Amateur Gardeners' Society dealing with their twenty-seventh season. This small society seems to me to embody a great deal that is of great value to horticulturists both in rural and in suburban communities. It was founded in 1899 and its principles are:

1.—To further the interest of gardening among amateurs in the neighbourhood of New Barnet.
2.—To afford opportunities for the exchange of opinions and experiences of its members.
3.—To bring its members into friendly rivalry on the show benches.
4.—To arrange, during the summer months, visits to places of horticultural interest in the county.
5.—To arrange for the holding of lectures on horticultural topics.

These principles are excellent and very much to the point. In a short history of the Society the secretary mentions that the fortunes of the Society have fluctuated and that "it has, in fact, on more than one occasion been on the verge of collapse, but an appeal to its members to advertise the Society has each time brought about a revival." At the present moment there appear to be over a hundred members, which, although satisfactory, must only include a percentage of the keen amateur gardeners who live around New Barnet. That thirty-nine of these hundred odd members exhibit at the three shows held yearly by the Society shows that the members are not satisfied with paying their subscriptions and leaving the exhibits to others, for this is a very high average.

The first show this year is being held on April 18th, the second on July 4th, the third on September 12th. The schedules are divided into four sections, flowers and plants, fruit, vegetables, ladies' classes, while the actual classes are simple and such that the owner of even the smallest garden can compete. As well as ordinary awards, aggregate prizes are presented every year by Messrs. Cutbush. In addition to the report and schedules the booklet gives a page of hints to new exhibitors, another on the staging of vegetables, a third on some garden friends, as well as a useful table for vegetable growers.

The whole of the cost to the Society last year, including printing, hire of hall, prizes, etc., came to £30 17s., which is not a large sum. The income is raised by a subscription of 5s. per annum from men and 2s. 6d. from ladies. This shows that with skilful encouragement such an amateur gardeners' society can be run successfully at very little cost.

This short résumé of this little booklet proves what can be done in an average suburban community. That this Society has survived twenty-seven years, including the war years of 1914-18 reflects great credit on its organisers and I hope it grows from year to year as it undoubtedly deserves to. This form of society is of the greatest use in helping the ordinary amateur who is often unable to provide more than an occasional day's hired help for his garden. There are numbers of similar societies throughout the country, but every neighbourhood in which there is a nucleus of keen amateurs would be the better for such a society. The rules of this society are simple and the advantages to its members obvious. The number of plants to be shown in each class in the schedule are few and consist of ordinary plants to be found in every garden.

I have spoken before of the fact that whereas the trade keeps up the quality of its goods by constant selection and introduction of new forms, the successful cultivation of the plants rests with the grower. The three shows held by this Society every year no doubt go a long way towards keeping up the standard of cultivation in the neighbourhood of New Barnet by the spirit of friendly rivalry they must instil into the members of the Society. It is this friendly rivalry that is so important in keeping up the standard of cultivation, for, naturally, conditions of soil and climate are approximately the samewith in a small area, and everybody knows that what one can do in skilful cultivation can be accomplished by all.

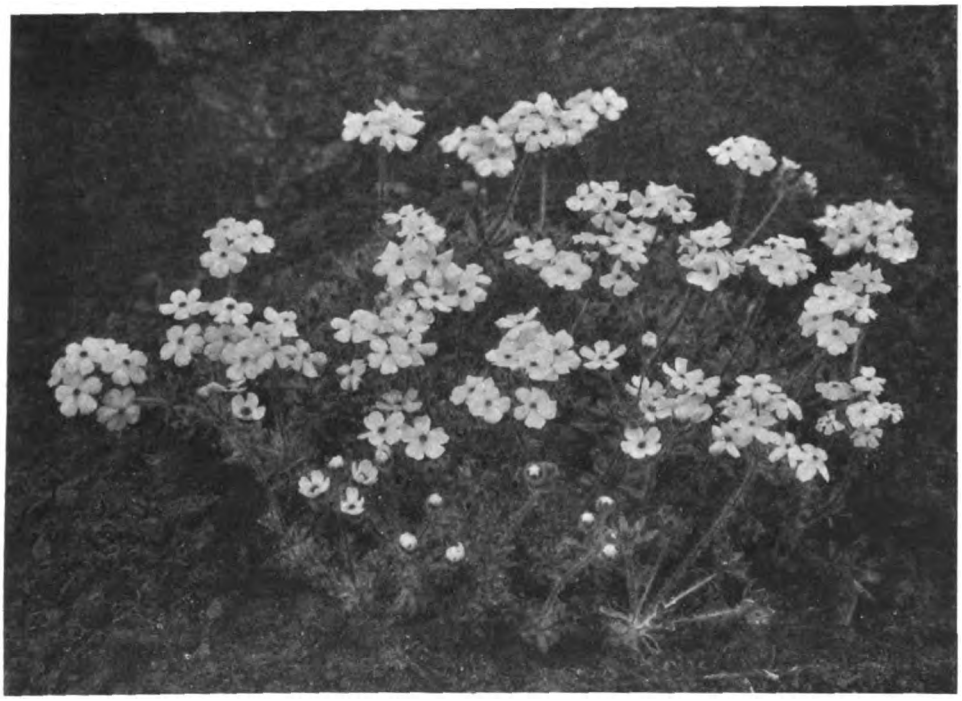
RE-CONDITIONING THE ROCK GARDEN

THE time for this work is during the late autumn, all through the winter when the weather is open and mild, and in the early spring. During these months there is much to be done in the rock garden, one of the most important being the operation of top-dressing all those plants that require it. Many plants, like some of the stem-forming primulas, have a tendency to run up and grow away from the surface of the soil, with the result that they appear straggly and leggy. When top-dressed with suitable soil, fresh roots are emitted higher up the stem, and thus the plants benefit to a great extent by this being performed when necessary. The spreading mossy phloxes, aubrietias, achilleas and other similar carpeting plants should also be attended to. For the purpose of top dressing, a compost of loam, leaf-mould and sharp grit should be used. Chop up the loam as small as possible, and pass through a sieve to separate all coarse lumps, then add the other ingredients and mix well together, and place under cover where it can be kept dry. The mixture should be worked well in between the prostrate stems, and where there is room between the plants the soil should first be stirred up slightly with a hand fork and all weeds cleared off. Care must be taken that the top-dressing is not too heavy, and for plants like the androsaces, more grit must be added in proportion to the soil used. The requirements of various kinds of plants must be borne in mind as the same compost will not do for all. For instance, Gentiana verna will respond to a dressing consisting of a good proportion of old mortar rubbish; Androsace villosa and Asperula arcadiensis prefer granite chippings with a little leaf-soil, while some of the primulas benefit by the addition of well decayed cow manure to the mixture employed.



ANDROSACE VILLOSA, WHICH BENEFITS BY THE ADDITION OF GRANITE CHIPS AND A LITTLE LEAF MOULD.

A DRESSING OF OLD MORTAR RUBBLE GIVES EXCELLENT RESULTS WITH GENTIANA VERNA.

The transplanting or re-planting of such plants that have exhausted the soil in which they are growing should be finished off as early in the spring as possible. The best time for this is in the autumn months, so that it gives the plants time to get established before the cold weather sets in. They are then ready to produce their flowers as soon as the weather permits in early spring. At the same time, if such work could not be carried out in autumn, it may with safety be performed in the early spring. With care and attention to watering during the dry weather, no ill effects should be encountered. All pockets that have got sour or exhausted should be emptied, and refilled with a good compost suitable for the particular plant that is going to occupy it. If the natural soil is at all heavy plenty of drainage in the shape of broken bricks or stones should be placed in the bottom before refilling up with the soil. The stronger, free-growing plants that show signs of exhaustion should be taken up and replanted in a larger pocket in fresh soil, or if they are to go back again in the same position, only a portion should be planted, selecting the stronger and healthier crowns for the purpose. It often happens that a coarse-growing plant is situated near to a choice slow-growing one, and where there is danger of the strong one over-running the other, one of them must be moved to a more suitable position. One must always be on the lookout for this kind of thing in the rock garden.

It is a good time now to do any rebuilding that requires to be done, as with the stones away it is so much easier to replace the worn-out soil with new, and when the plants are put back again they get a good start. It is a good plan to rebuild portions of the rock garden from time to time for this purpose, but where there are large specimens in the way, that it would be dangerous to move, these could be left and built up without disturbance. All plants that have got into a weak condition, or have gone off from various causes, should be removed, fresh soil put into the pockets, and fresh plants from the frames put in their places. All vacant places should be planted up as soon as possible if the weather continues open, but

Digitized by Google

plants from pots may be planted at almost any time when necessary, even in the height of summer, if supplied for a time with shade and water.

One of the most important features of a rock garden is correct and legible labelling. This entails a great deal of time where large collections are to be kept correctly named. Labels should be chosen that are not obtrusive in the general effect, but are easily read when close. Several neat and useful labels are now on the market, one of the best being a small one on a stand or leg a few inches long. The material used is glass, coloured green, with black burnt-in letters, either block or script, the former being more distinct and easily read. Others are made of metal with raised letters, which can be kept bright by using emery cloth or sand-paper. Wooden labels, although necessary, are too conspicuous to please one who cares for the appearance of his rock garden. Lists should always be made in fair weather of all plants that want re-labelling, so that labels may be prepared on wet days, or in hard frosty weather, when no work is possible outside.

ONE OF THE CHOICER ALPINE SUBJECTS, OMPHALODES LUCILIÆ, WHICH SHOULD BE CAREFULLY TENDED.

A sharp look out must be kept at all times for slugs and snails, which have their special favourites among alpine plants. Among those specially liable to attack are Omphalodes Luciliæ, Aster alpinus, Campanulas of the smaller kinds like C. Allionii, C. Zoysii and C. Saxifraga, Crepis aurea, and most other plants that have succulent leaves and buds. If neglected, the growing points are liable to be eaten out, with the result that there is no flower the following season. One good method of catching slugs is to put down here and there little patches of bran covered with a piece of slate or glass to keep it dry. This bran forms a great attraction for the slugs and they can be caught in large numbers at night. For special plants it is advisable to examine them periodically when the slugs usually come out to feed. Another method of keeping away slugs is to spray the plants with a solution of alum, which renders the plants distasteful to them. Dead leaves and decayed matter form a good harbour for slugs, so these should not be left on the plant, but cleared away as often as possible, keeping the whole place clean and tidy.

Among other things the bog garden will require overhauling, as many of the stronger-growing plants will have exceeded the space available. Such plants must be taken up and divided, re-planting only a small portion. Where they cannot be taken up the clumps can be reduced in size by chopping off the superfluous parts, or thinning out the crowns. Many bog plants come up freely from self-sown seed, so that it is necessary to weed, and thin out thoroughly, before growth commences in spring. After all the plants have been reduced to their proper proportions the whole surface can receive a good top-dressing of loam and leaf-mould, to which has been added a good proportion of sharp, gritty sand. Those bays or pockets in which peat-loving plants are grown, of course, must be supplied with a mixture of peat, leaf-mould and sand. The wall gardens must also be attended to, as frost has probably loosened many stones, and consequently the roots of some plants will be exposed. Fresh soil should be rammed in to make them all tight, and where there are vacancies these can be filled up with young plants from the nursery. Plant these very firmly, and work the soil well back so that there are no cavities in the rear. When well furnished a wall garden is one of the most attractive parts of the rock garden, with its pendent curtains of bloom in spring, furnished by such plants as Iberis Garrexiana, Dianthus cæsius, D. plumarius and Cerastium tomentosum, and others. Among the many foliage plants are the silvery-leaved Artemisia lanata, A. vallesiaca, Chrysanthemum ancherianum and Erodium chrysanthum, to mention only a few that are valuable for furnishing an old wall. When this is all done we may await the promised display of beautiful sheets of flowers in the near future. W. I.

POTATOES FOR ALL PURPOSES

I HAVE spent the greater part of my life in one of the great potato-growing districts of Yorkshire. The soil in this locality, where potatoes are the chief crop, may roughly be divided into two types: (1) a light loam, and (2) the warp lands. The former class of soil is considered an ideal medium, for in it most varieties can be grown to advantage. The loose nature of the soil enables it to be cultivated at any time, and also, when the tubers are developing, there is no hindrance to their formation. On the warp lands, which consist of alluvial deposit from the rivers, the sodden nature of the soil after a wet period defers ploughing, etc., and it frequently happens that planting is late. Should the summer be dry, however, these warp lands retain the moisture when more porous soils are parched, and consequently potatoes continue growth when others have died down. Certain varieties, such as King Edward, invariably do well on the warp lands.

Much is often written in the gardening Press concerning the advisability or otherwise of planting potatoes directly on the animal manure in the rows. As this is the usual practice in this district, and has been for many generations, its safety can be taken for granted. Perhaps it may interest readers who do not live in a potato-growing district if I explain briefly the method of manuring and planting adopted by the farmers in the Vale of York. Rows are made with the plough, and then carts bring manure from the farm into the field. This is thrown in heaps at intervals along the rows, and workers follow along spreading the manure so that a thin covering is left down each furrow. This is usually allowed to remain for a day or two until the whole field is manured. A dressing of sulphate of ammonia is then scattered broadcast over the rows, and the potatoes are planted, either by hand or by a machine known as a "setter." After the potatoes are planted—*i.e.*, laid on the manure in the rows—they are then earthed up with the plough. This is a preliminary earthing-up, the proper banking up of the rows taking place later. To those critics who assert that planting potatoes directly on animal manure is

Digitized by Google

the way to produce disease I ask the question: "If this is a wrong method, why have the farmers, on whose livelihood the success of the potato crop depends, not adopted another course?" I have proved beyond doubt that to plant potatoes directly on animal manure is not to produce disease. When a potato tuber commences growth it must have plenty of manurial elements near its initial roots, hence the placing of animal manure and artificials close to the initial growth.

Quick acting fertilisers, such as sulphate of ammonia, are necessary to ensure rapid growth in May and June. The beneficial use of this can be proved by testing two rows, one in which a dressing of sulphate of ammonia has been given and the other where it has been omitted.

In my own trials, during the past few years. I have endeavoured to find out from experience which varieties are most suitable for garden culture. The amateur who cultivates a plot from which the potato crop finds its way to his own table is chiefly concerned with one or two essential points. As a rule he likes a potato that is styled "a good user," and at the same time he desires a good crop. The size of the tubers is not such an important matter. If they are of medium size they suit his purpose as well as very large tubers would do. Unless he wishes to clean a certain plot of ground (and there is no better way of choking weeds than by growing a potato crop where the variety is of tall habit), a moderately tall or a short haulmed variety is admirable. Some growers adopt the plan of growing celery and potatoes together. A wide space is left between the potato rows and in this the celery trenches are made. The potato rows would thus occupy the ridges of the celery rows. For such a purpose a dwarf-growing variety should be used. I know an old farmer who has grown celery and potatoes in the same field for a number of years to great advantage. The variety of potato that he always uses is Ninety Fold.

It is generally known that there are two classes of potatoes when one is discussing cooking qualities. The floury or mealy type, of which Arran Chief is a well known example, is most popular. Some people, however, like a closer-textured variety, one that is commonly called "soapy." Such kinds are very tasty if they are roasted or fried in fat or dripping. King Edward is not regarded as a potato for the epicure, yet it is very popular with townsfolk. I have often wondered why this popularity should be, and have come to the following conclusions: (1) It is distinctive—a townsman calls it a pink potato as distinguished from the white-skinned varieties; (2) there are very few diseased tubers: if a buyer finds half a dozen bad tubers in every quarter of a stone that he buys he naturally has a dislike to paying for so much waste; (3) it can be cooked in any kind of way, and however used has a tolerable flavour; (4) you can leave it boiling in the pan and it does not turn black, even if dinner is delayed for half an hour or more.

With regard to my own trials I have noted the following points about the different varieties, some of which may be of use to growers who are making selections for the coming season. I might mention the advantage of growing Scotch seed.

FIRST EARLIES.

America.—White round; immune; rather rough and somewhat deep in the eye; resembles the old variety Epicure, but gives larger tubers and a bigger crop. Good cooking qualities. Strong dark green haulm.

Immune Ashleaf.—An immune variety of the old favourite with better cropping qualities; distinctive ash-leaf-like foliage, medium spreading haulm; kidney-shaped tubers of good flavour.

Di-Vernon.—A new immune variety that improves on acquaintance; kidney-shaped tubers with distinct purple colouring near the eyes; medium spreading habit, with dark green leaves.

Sharpe's Express.—A good cropper, but the cooking qualities are not quite equal to some of the other earlies. White flesh; kidney-shaped; non-immune; haulm upright and spreading.

Witch Hill.—An excellent first early that comes in just before the second earlies. Very good cooking qualities. A good cropper. Kidney-shaped, with shallow eyes. This variety will keep well, and can be used along with the main-crop varieties if needed. Immune.

Arran Rose.—A coloured potato; pale rose, with a netted skin that denotes good cooking qualities. I find this variety gives quite a good crop. It is also a good exhibition potato. Immune.

SECOND EARLIES.

Arran Comrade.—An ideal potato for the garden. It is an excellent cooker, being quite equal to Arran Chief in quality. Round, evenly sized tubers with shallow eyes. Ideal habit. Immune.

Katie Glover.—A new variety of distinct colouring. The tubers are pebble-shaped, with a pinkish flush around the eye. The crop is above the average, although there are few large tubers. Good cooking quality, and it also keeps well. It has a splendid habit. The foliage is of medium height and affords plenty of cover.

Great Scot.—A very popular variety, and deservedly so. It gives a large crop, and although the eyes are sometimes rather deeply set and the very big tubers sometimes come hollow, these are the only faults one can find with it. It has a tall, upright and vigorous growth with dark green leaves.

Majestic.—A large white kidney-shaped potato that has rapidly come to the fore. It is an immense cropper, and although it has a smooth skin it is not a bad user. The skin is very thin, and because of this two points should be observed. It does not require too liberal a dressing of animal manure and it will not bear rough handling. Immune.

The Ally.—A very good user that may be described as a white oval variety. In some districts this is a very popular variety, and I should think that it succeeds best on a light loam. Immune.

LATE OR MAIN CROP VARIETIES.

Arran Chief.—Too well known to need much comment. It is one of the best table potatoes, and where it can be grown free of canker it should be regularly planted, as it is a big cropper.

Golden Wonder.—This is THE potato for the epicure. It is among potatoes what Cox's Orange is among apples. It has a nutty flavour and cooks very floury. Not a very big cropper unless grown from Scotch seed. I grew a very select stock from Fifeshire in 1923, but the tubers saved from this stock did not yield such a large crop the following season.

The Bishop.—I consider this one of the best of the main-crop varieties. It is an ideal exhibition variety, giving beautifully formed kidney-shaped tubers with very shallow eyes. The haulm is medium and slightly spreading. Immune.

Roderick Dhu.—The tubers are round to oval, rather deep in the eye, but of good quality. The haulm is tall, upright and very vigorous. A variety to plant where rough ground is being cleaned. Immune.

Crusader.—A kidney-shaped variety with shallow eyes. It is a good cropper and the quality is fairly good. It has a vigorous upright growth.

NORMAN LAMBERT.

SOME GARDEN IRISES

BY W. R. DYKES.

IN recent years irises have become much more popular as garden plants than they were twenty or even ten years ago and many beautiful new varieties have been raised by hybridisation and are now available in this country. There are many good irises, one or other of which will be in flower at intervals throughout the year and which deserve to be far better known than they appear to be at present.

Take, for instance, the Algerian I. unguicularis or stylosa, which, when established at the foot of a south wall in soil containing a good proportion of mortar rubble, will begin to flower in October or November and continue into February and March. In how many gardens is this beautiful flower still unknown!

No one expects to have Christmas roses at their best in December and January without covering the plants with glass, and yet the irises which flower in the first days of the New Year are neglected because the blooms need the same protection if they are to last their full time of a week or ten days. Few sights are, however, more charming in January than a cold frame filled with the brilliant blue flowers of I. histrioides or with the gorgeous colours of I. Rosenbachiana. Of the latter I have raised several hundreds from seeds, of which I obtained my first supply from Sir Michael Foster as long ago as 1906. There is infinite variety in the colours of the flowers, which rise to a height of 4ins. or 6ins. above the sheath that still encloses the young

Digitized by Google

leaves. A little later come I. persica and its relatives, I. Tauri, with its flowers of dark red-purple and gold, and I. stenophylla, with its two shades of blue-purple. Even more attractive is the hybrid persind, with beautiful pale turquoise blue flowers.

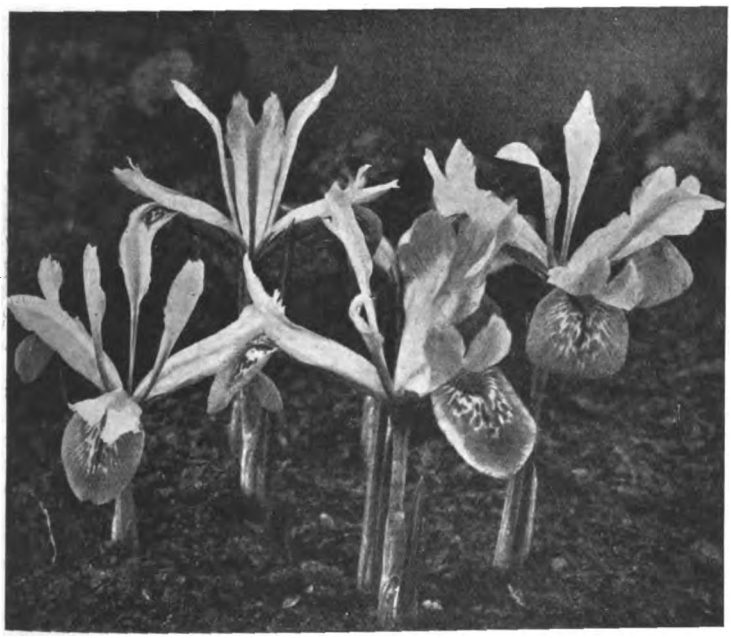
It is difficult to understand why the more vigorous of the Juno irises, such as I. bucharica, are not more widely known, and yet there are few more beautiful bulbous plants that flower in April than this species and some of its hybrids. They are perfectly hardy and grow well in any light, rich soil that is not slug infested. The plant grows to a height of about 20ins. or 2ft. and each stem bears as many as six or seven white and yellow flowers in the axils of its broad, shining leaves. These irises are no trouble whatever to grow for they may be left undisturbed for about three years, until in fact the bulbs become so crowded that it is well to lift and separate them. The fleshy roots, which remain attached to the bulbs during the resting season, are very brittle when they are first lifted, but become tougher after a few days, and it is better therefore to wait a week before attempting to separate them. They should be lifted, when necessary, in July, and nothing is gained by keeping them out of the ground after September. The best position is a sunny border sheltered from the north and it must be remembered that the bulbs will not tolerate disturbance except when they are at rest during the summer months. Lifting in October

I. Douglasiana, of which every seedling seems to be different in colour and markings, while I. tenax is even more floriferous, though its foliage is deciduous. These Californian species like a light, rich soil and will not grow satisfactorily in chalk.

Two larger species, I. longipetala and I. montana, are vigorous enough to hold their own in a mixed border and are more at home in a heavy soil than those previously mentioned. Moreover, they will tolerate some lime in the soil.

Another good border species is I. graminea, though it is a plant which many would pass without comment. The flowers of red and blue-purple are richly coloured enough, but often hide themselves among the close-growing foliage. Their special merit is that they have the sweet fragrance of a warm, ripe plum. I. graminea is easily raised from seed; it will grow in any good border soil and may remain untouched for several years. If the clumps have to be moved, the best time is the late summer, when fresh roots are still pushing out from the slender, hard rhizomes.

Taller relatives of I. graminea, namely, I. ochroleuca, I. Monnieri and I. aurea, are all good border plants, valuable for their tall stems, rising to a height of 4ft. or more, and for their stiff, upright foliage. The first has flowers of white and yellow, the second is a pale lemon yellow, while the third is of a deep golden yellow. They all do well in rather stiff soil and flower



THE CHARMING BRILLIANT BLUE FLOWERS OF IRIS HISTRIOIDES.

THE DAINTY IRIS ROSENBACHIANA, WITH BLOOMS OF THE MOST GORGEOUS COLOURS.

or November with the occupants of an ordinary herbaceous border would probably be fatal.

Not every gardener seems to realise the fact that the best way to ascertain when to move a plant is to examine its roots, and not every gardener seems to be aware that bulbs differ very much in their methods of root formation. Some, such as tulips and crocuses, produce annually only one crop of roots and, if the bulbs are disturbed after the roots have grown in the autumn, they will certainly be severely checked and take a year or two to recover their strength. Fritillarias behave in the same way, but their roots are so fragile that the check is even more severe, and so it is with bulbous irises.

In these labour-saving days, when more and more of our gardens are being planted with flowering shrubs, there seems no reason why we should not plant between them some of the Californian species, several of which are practically evergreen and all of which have a comparatively long flowering period. Seeds should be sown in pots in the open in the autumn. As soon as germination takes place, the pots should have the protection of a frame or cold house and the young plants should be encouraged to make rapid growth. They will then be big enough to be planted out in their permanent positions before the end of May and, given a favourable year, some will flower in the following season. The best species for this purpose is best if they have abundant moisture during the growing season in spring and early summer and a thorough ripening when their growth is over for the season.

Some forms of I. ochroleuca are the tallest of all irises and among the smallest are I. cristata and I. lacustris, two American irises, of which the former is 4ins. or 6ins. high and the latter only 2ins. or 3ins. These should be grown in a moist, half-shady position in a soil composed of well rotted leaves and fine gravel. Never plant these irises in the autumn, for failure is then almost certain, unless indeed they are obtained in pots. The best time to begin is in June, a week or two after the flowers have faded. Then it will be found that each flowering shoot has branching out from it three or four young tufts of leaves. These should be cut off and re-planted immediately. They must then be kept moist for a few days and will quickly send out new roots and each one should flower in the following season. When I. cristata is treated in this way it will produce sheets of its pale lilac flowers in May, so closely set as almost to touch each other. A moist, half shady position, such as that which suits primroses, is also the best for the daintiest of all irises, I. gracilipes, which flourishes in copses on the hillsides in Japan. Hot sun will soon shrivel the slender rhizomes, which are, however, easily cultivated in such a position as that described. The plants should be frequently top-dressed with well rotted leaf-soil

HONEYSUCKLES

BY EDWIN BECKETT.

THIS GENUS IS A WIDESPREAD ONE, COMPRISING SOME HUNDRED AND FIFTY SPECIES, MANY OF WHICH ARE USEFUL IN THE GARDEN FROM THE POINT OF VIEW OF DECORATION.

TOWN bred, or country bred, there are but few folk who would not recognise the fragrant honeysuckle or woodbine growing wild on an English hedgerow, or fail to experience a thrill at the sight of its rambling beauty, or enjoy its fragrance. Unfortunately, the thrill is generally rapidly replaced by a covetous desire to possess, and the floral gem is thereafter ruthlessly dragged from the host plant which supports it. If, however, some of the other hundred and a half forms of honeysuckles were before them, how many would recognise them as such, or how many would realise that there are two very distinct groups, to wit, the climbing and the bush species and their varieties, each group well distinct in growth, and yet most closely linked in character. At Aldenham we have from time to time possessed about ninety different species and varieties, and we have record of over another sixty that have yet to chance our way. Some are beautiful in flower, others in fruit, and worthy members of a good shrubbery,

A BEAUTIFUL SMALL FLOWERED FRAGRANT SPECIES FROM CHINA, L. SYRINGANTHA.

while a number are more interesting than lovely, and must therefore be relegated to the wilder parts. Some are climbers, some are bushes, some evergreen, some deciduous, some fragrant, and others lacking this attribute, and a large and useful family they prove in a comprehensive collection of trees and shrubs.

As a group they might well be classed for general utility even ahead of the very lovely berberis family, for surely there is not a part of the garden that cannot have its representative honeysuckle. There are a number of climbers, for instance, that can grace the wall of a house, assist in furnishing a pergola, or help to disguise the bole of a dead tree. Others, again, can act as specimen plants on lawns, or help in the formation of the shrubberies, either in bush form or climbing up poles placed for the purpose. Some can brighten the woodlands, and one in particular is an ideal hedge plant, but even yet, among shrub enthusiasts and lovers, it is doubtful whether the family has come truly into its own. In passing it is as well perhaps to record that, coming under the Natural Order of plants known as the Caprifoliaceæ, the honeysuckles are closely related to those other charming flowering and fruiting families of shrubs, the diervillas, abelias, viburnum and elders.

Our purpose on this occasion will be to try to assist them to emerge from their comparative obscurity by considering some of the more beautiful and useful, and the desire of the enthusiast to record the whole of them, their virtues and individual glories, will therefore be strictly avoided.

THE CLIMBERS OR WOODBINES.—These for botanic classification have been grouped under a sectional heading entitled Periclymenum, or Caprifolium as some authorities term it, in contra-distinction to the bush forms, which are classed as Chamæcerasus, or by some as Xylosteum. There is an intermediate group of creeping and climbing species classified as Nintooa, which are sometimes considered as a sub-section of the Chamæcerasus, but which for convenience sake are ignored in these notes as a group and dealt with under the climbers.

A tender species must be referred to first of all, one that will only succeed in the open in the congenial quarters of this country, such as the south-western counties. It is Lonicera Hildebrandtii, a Chinese native, of very large foliage, and bearing clusters of orange coloured fragrant flowers of gorgeous appearance, the trumpets of which run nearly 6ins. in length. More or less tender in some parts, unfortunately, is the American L. sempervirens, another lovely trumpet honeysuckle, the flowers being a rich tone of orange scarlet without and yellow within, but only about 2ins. to 3ins. long. Compensation exists, however, in another from the same country, L. ciliosa, an old but very rare species here, very beautiful with its terminal spikes of yellow to orange flowers, and there is also the beautiful species from China, L. tragophylla, sent home by Mr. Wilson. It carries terminal heads of from a dozen to twenty bright yellow flowers, fragrant, and 3ins. or more in length. L. flava (America) is a pretty orange yellow, and there is a beautiful species of garden origin, L. plantierensis, and similar forms under various other names, such as L. fuchsioides, which carry glowing red flowers with orange-toned lobes. To finish the flowering climbers we have the ever-precious old L. Periclymenum, or native woodbine, with its flowers yellowish white to red and so sweetly fragrant, of which there are several varieties, the principal of which are L. P. belgica, the Dutch honeysuckle, with purplish red flowers with yellow throats, and L. P. serotina, a late form with purplish flowers, interiors creamy, darkening with age as the exterior of the corolla lightens.

FRUITING CLIMBERS.—Some of the climbing species would be selected for their fruiting capacity rather than for floral beauty, and principal among these would seem to be Wilson's L. alseuosmoides, an evergreen with flowers of purple (yellow within), which are followed by black fruit freely borne. Closely related to this are two others, L. Henryi, with larger leaves, and bronzy orange flowers, followed by purplish black fruits; and L. Giraldii, with distinct bronze-toned foliage and purplish red flowers. All three of these are Chinese natives.

EARLY-FLOWERING BUSH SPECIES.—There are two Chinese species that are always worthy a place in a garden owing to their very early flowering, both being also deliciously fragrant. The earliest is probably Lonicera Standishii, which opens as early as November and continues to February. Mr. Wilson sent home a narrow-leaved form of this called L. Standishii lancifolia, but I do not think there is anything to choose between species and variety with regard to hardiness or beauty. The other species is L. fragrantissima, a creamy white-flowered semi-evergreen, which starts flowering about December and continues until March or April.

Digitized by Google

A SPECIES OF RECENT INTRODUCTION, L. LIGUSTRINA YUNNANENSIS.

LATE-FLOWERING BUSHES.—We have probably a little more scope with those that follow the foregoing in the range from which to select, and here we will briefly consider four species. My first choice falls on Lonicera chætocarpa, again sent home by Mr. Wilson, a most lovely primrose yellow-flowered species, closely related to the old Asiatic species, L. hispida. Next, I should select another Chinese native, L. syringantha, a beautiful small-flowered fragrant species, blooming in May and June, the flowers of which, borne mostly in pairs, are lilac pink in colour. Close to this comes the third, L. thibetica, from the Tibetan Hills, the twin flowers of which are borne in small bunches in the leaf axils, and are rather more of a true lilac tone than the former. It is, I believe, rather more shy in its flowering than L. syringantha. The last one of the selection is quite distinct in appearance, though the flowers are again produced in twos, and of rosy lilac colour, being also sweetly fragrant. This is L. Albertii from Turkestan, of low spreading habit and with narrow (⅛in.) bluish grey foliage.

DECIDUOUS FRUITING BUSH HONEYSUCKLES.—There are many bush forms of good fruiting capabilities, and it is not an easy task to select the best, but a few seem to insist on their claims. Lonicera Maackii, for instance, that giant growing bush that one will keep in the shrubberies owing to its flowering and fruiting beauty, seems to come first, and with its white flowers, which turn a deep yellow tinge with age, and are followed by many scarlet twin fruits, must have a place. Then, again, the two American natives, L. Ledebourii, with deep orange yellow flowers, from Oregon, and L. involucrata from the north-western areas with yellow flowers, both having black fruit, deserve a place; and the curious pair, L. quinquelocularis and L. translucens from China, with their translucent fruits of whitish hue, like moonstones, must also be included as curiosities, if for nothing else. One other that deserves notice is the large-growing rounded bush form, L. chrysantha, which is such a lovely sight when clad with its bright scarlet fruits, which seem to be as freely borne as red currants; this comes, I believe, from Amur.

FRUITING BUSHES OF EVERGREEN CHARACTER.—The last for our immediate consideration are three evergreen species from China. Lonicera nitida, the first, is probably one of the finest evergreens yet received from those vast regions, and is the one referred to earlier as being ideal for the formation of hedges. Of fairly stiff, upright habit, it looks at first sight like a very dainty glossy-leaved privet. It is a pretty sight when bearing its small, round, violet berries. Closely allied to it, but of more prostrate habit and longer foliage, is L. pileata, eminently suitable for a "headland" on a large rockery. This, too, carries amethyst fruits, and the last one of all is a wonderful sight when clad with the same toned fruits, borne nearly as profusely as those of Cotoneaster horizontalis. This is of more recent introduction, and has been accorded the formidable title of L. ligustrina yunnanensis.

SOILS AND ASPECTS.—A few words in closing will suffice on this subject. I do not think that loniceras can be considered at all troublesome as to their soils, for they seem to thrive equally well on very different kinds, though possibly fruiting the more readily on the warmer, lighter, moister loams, and as to aspect, well, we grow them in shade and sun, in sheltered spots and exposed positions, and still they seem quite happy under all, and give very little trouble, and in making a selection from the foregoing the would-be grower will not, I think, have to worry greatly on these two, at times, important propositions.

A RARE ASTER

OUR picture shows a small, daisy-like herbaceous perennial that is seldom met with in our gardens. It is Bellidiastrum Michelii or Aster Bellidiastrum from the Alps and the Jura. Its white flowers are rather similar to those of Bellis sylvestris, and usually appear in great numbers during the months of June and July or even later.

I took the photograph in a very interesting place in Lower Austria, at Purgstall, the residence of Count Herbert Schaffgotsch, who is one of the keenest amateurs of alpine plants. In the rocks through which the green waters of the Erlaaf are swiftly running bellidiastrum may frequently be seen in a half-shady place. It is easily propagated by division and seed, and cannot be recommended for a small rockery, except in a position where it can bespread itself; it is of no small ornamental value during its flowering time. CAMILLO SCHNEIDER.

BELLIDIASTRUM MICHELII, MORE LIKE A DAISY THAN A STARWORT.

THE MANURE PROBLEM—II

THAT the effects of artificial manures are very largely controlled by weather conditions makes efficient manuring more difficult and partly explains why it is impossible to adhere to hard and fast rules. At the best it is only possible to generalise and it behoves the gardener and cultivator of the soil to "put his thinking cap on," to grasp the general principles of manuring and proceed.

The functions of the chief groups of manures have previously been touched upon and it is now desirable to discuss more generally the functions of the individual manures comprising these groups.

THE NITROGENOUS MANURES.

The nitrogenous manures comprise a large group and include both artificial and organic substances, the functions of the latter are best left for discussion until later on.

NITRATE OF SODA.—Generally speaking nitrate of soda should not be used on heavy soils; it has the undoubted effect of destroying the tilth and making the soil to a great extent unworkable—exactly how this is brought about is best left to the scientist to explain. Lime is no use to counteract such a condition, but applications of an acid manure, such as superphosphate, have a good effect.

Nitrate of soda is useful apart from the nitrogen it supplies to the plant. The soda it contains (although of no use directly to the plant as a plant food), is effective in releasing the insoluble potash contained in the soil, thus making it useful to the plant, indeed, this releasing of the potash is so effectual in some soils that it does away with the necessity of applications of soluble potash manures. The effect is chiefly noticeable on medium and light soils, but on the very light soils—where potash is usually very deficient—the soda seldom makes up for the deficiency of potash.

Nitrate of soda is so often termed a soil scourge that such criticism must be met. It is true with nitrate of soda—and with, indeed, any other active fertiliser supplying only one plant food—that if used alone regularly it depletes the stores of other plant foods in the soil. The deficiency must be remedied by applications of the used-up plant foods, *i.e.*, potash and phosphates.

The chief value of nitrate of soda over other manures is that it is of immediate use to the plant The chief points to bear in mind when contemplating using nitrate of soda are:

Do not use it on a heavy, clayey soil.
Use it with phosphate and potash.
Use it only on crops which can make immediate use of it.

The quantity to use for general purposes is from 1lb. to 1½lb. per square rod of ground.

SULPHATE OF AMMONIA.—A *sine qua non* for sulphate of ammonia to give the best results is that the soil should contain calcium carbonate to counteract the acid conditions set up by the manure. It is generally accepted by practical cultivators of the soil that better results follow from the use of sulphate of ammonia in a wet season, owing to it not being so easily washed out of the soil, but this view is not always a popular one with scientists. It has an advantage over nitrate of soda, in that applications of it do not act adversely on the tilth of the soil, in fact, they tend to improve it. It is also useful from the point of view that it can be mixed with other popular manures, where nitrate of soda cannot, and is especially valuable for the potato crop. Its application is similar to that of nitrate of soda.

NITRATE OF LIME.—This fertiliser is chiefly valuable as a substitute for nitrate of soda on heavy soils. Its effect on plant growth appears to be similar to that of nitrate of soda, but the lime it contains has its beneficial action upon heavy soils. It should be applied in spring. It is very necessary to keep the fertiliser dry and covered up, as it readily absorbs moisture and becomes difficult to use when exposed to the air.

Some new introductions in nitrogenous manures are being tested and some of them are likely to prove very attractive from many points of view.

THE PHOSPHATIC MANURES.

SUPERPHOSPHATE OF LIME is the most popular manure in this class, its popularity undoubtedly being due to its quick action and usefulness on most soils. A condition necessary for its success, however, is the presence of calcium carbonate in the soil on which it is used. Superphosphate is chiefly beneficial to the shallow rooting crops and is especially valuable for potatoes. These results are explained by the fact that much of the phosphoric acid contained in the superphosphate remains in the surface soil.

BASIC SLAG.—Applications to heavy soils often give superior results to superphosphate. The lime it contains is of assistance in improving the texture of the soil, and also in releasing potash. There is a very marked prejudice against the use of basic slag on light, dry soils and practical men seldom recommend its application to such soils, since their dryness is said greatly to minimise the effectiveness of the manure. This prejudice, however, is not universal, and good results have followed an application of basic slag on similar soil, deficient in carbonate of lime, but a condition for its success appears to be a wet season. It is probable, too, that the good results in some cases are due to the lime contained in the slag.

BONE MANURES.

From a gardening point of view it is questionable if the use of bone meal is justified by its price, except when used on lawns, where good results are often obtained. Bone meal is very slow in its action and its comparative ineffectiveness is said to be due to its coarseness. Bone meal and steamed bone flour are best treated as substances supplying phosphates, although a certain amount of nitrogen is supplied.

STEAMED BONE FLOUR.—The fineness of this production makes it more valuable than bone meal for supplying phosphoric acid, and from many points of view it should be purchased in preference to bone meal owing to its quicker action.

POTASSIC MANURES.

The soils which benefit usually from applications of potassic manures are the sandy and gravelly ones.

SULPHATE OF POTASH is from many points of view the most satisfactory form in which to supply potash; for crops under glass its usefulness is every year becoming more manifest in building up the constitution of plants and protecting them from attacks of fungi. In some cases of attack of "stripe" disease on tomatoes the plants have completely recovered when applications of sulphate of potash have been given. As a constituent in a complete fertiliser it is indispensable for potatoes.

KAINIT.—It is absolutely essential that kainit, when used, should be applied in autumn and winter to get rid of the harmful substances it contains. It is not such a popular manure as sulphate of potash, although on some soils it has produced excellent results. When applied to potatoes it appears to lower the quality of the tubers. H. C. ELSDON.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

A SIGN OF SPRING AT VINCENT SQUARE

WITH every fortnightly show at the Royal Horticultural Society's Hall, Westminster, one notices a great difference in the number and, above all, in the quality of the exhibits, and on February 24th one was not disappointed, as a distinct advance had been made from that in the previous show. Despite the inclemency of the weather the exhibits were above the average for this time of year. All branches were represented, from alpine and rock plants to flowering shrubs and roses, and bulbs in the shape of tulips and hyacinths. Greenhouse plants were chiefly represented by cyclamens, which were in excellent condition and which, along with the carnation groups and the azaleas, lent a touch of brighter colour to the Hall. The ever-increasing interest which is being taken in all matters pertaining to gardening and general horticulture was manifested by the large attendance.

On entering the Hall one of the first sights which arrested the attention of visitors was the bed of fresh green grass with drifts of crocus, shown by Messrs. Carter and Co., and then, as the sweet and pungent scent of hyacinths reached the onlookers, they glanced in the direction from whence it came and one look made them eager to see more closely the excellent exhibit of Messrs. Bath and Sons. Hyacinths and tulips of every colour, crocuses, daffodils and narcissi were all grown to perfection in bowls, so that the remarkably strong and vigorous growth could be well appreciated. The hyacinths were exceptionally large and fine in colour. Schotel was a lovely clear blue, shaded with lilac and the fleshy bells were borne loosely on a long spike. The pale and delicate lavender-blue flowers of Enchantress were more compact than Schotel. Pure white hyacinths are always attractive. For spotless whiteness and regularity in shape there was hardly one to equal La Grandesse. One of the best late varieties, King of the Yellows was exhibited and delicate in colour was the blush pink of Jacques.

Both in hyacinths and tulips a deep purple seems to be one of the most popular shades. For indoor decoration this tone is well adapted, but the reds, pinks or mauves are much more effective for bedding. Among the hyacinths shown by Messrs. Bath, the variety L'Esperance was of this shade, the bells were small, but compactly arranged on a long spike. Both the tulips Van der Neer and Queen of the Violets were purplish in colour. The flowers of Van der Neer were large and somewhat heavy in appearance. Two good bedding tulips, Cramoise Brilliant, a vivid vermilion scarlet with a yellow centre, and Duchesse de Parma, an orange red edged with yellow, were particularly noticeable. The crocuses were perhaps a little too tightly packed in the bowls, but the masses of flowers so formed made a pleasing contrast with the yellow narcissi. There were pale mauves, deep mauves, whites with large orange anthers, as well as Pallas, a white, prettily veined with mauve and the rich purple Purpurea grandiflora.

The trumpet daffodils, the incomparabilis, the Barri, and the polyanthus were a few of the types of narcissi represented on Messrs. Bath's exhibit. All of them were very robust and good in colour. The deep gold flowers of King Alfred on stems almost 24ins. in length, stood out from among the rest. A sweetly scented variety was Victoria, which has a creamy white perianth and rich yellow trumpet. W. P. Milner seemed very dainty and small beside the large trumpet varieties. Several of the narcissi shown by Messrs. Barr and Sons, especially some of the unnamed ones, were very fine. Narcissus Maximus had pointed, twisted petals and was deep orange, and N. Alasnam was exceptionally large.

The lachenalias shown by Messrs. Barrs added greatly to the interest of the group.

THE FREE FLOWERING LACHENALIA, EXCELSIOR SEEDLING.

These early spring-flowering greenhouse plants are almost unique in colour and texture. No other flower possesses quite the same shade and waxy appearance. The beautiful orange colours and free-flowering habit of the lachenalia were well displayed by this exhibit. Deepest in tone were the seedlings, which seem to be a very good strain. Leiden, with orange flowers borne on reddish stems, and Monte Carlo, with golden flowers shaded with red, were two good varieties. Nelsoni and Siam, which have been raised quite recently, are a marked improvement on the old varieties.

Two of the best and most outstanding exhibits were of cyclamen. Messrs. Sutton and Sons had a magnificent display and the Caledonian Strain Floriculturists staged a larger and more varied collection than at the last fortnightly meeting. The varieties on Messrs. Sutton's stand were arranged separately in bold groups and the intervening space was bedded with moss. In this way the contrast between the different colours could be well appreciated. The development of this plant was cleverly brought home to the onlookers by the introduction of the modest and dainty Cyclamen persicum, the source of the florists' cyclamen, especially when comparing it with such a variety as Giant White. The brilliancy of the colours, the strength and large number of flowers on each plant must have been commented on by many people. This firm has set a high standard of culture for the average grower to attain. Firefly and Giant Shell Pink were two of the best colours. Neither of them possessed the bluish tinge which is present in so many others. Firefly was a vivid cerise scarlet, alive with colour, and Giant Shell Pink had large flowers; the base of the petals were pinkish red and the white ground was shaded with pink, giving the appearance of the pink having run into the white. Giant Crimson and White had to a slight extent this shaded effect. Hydrangea was a mauve-red, and for depth of colour the rich velvety crimson of Vulcan was unsurpassed. Other good varieties were Giant Salmon, White Butterfly and Queen Mary. Giant Ruby, although not so good as some, was interesting, as it was sown during February last year and commenced to bloom in October. This is an excellent proof of the usefulness of the cyclamen.

The Caledonian Strain Floriculturists excel in the frilled varieties. Lady Helen Cassel was again shown and is more attractive than the new sport, a double flowering pink; this was good in colour but inclined to look heavy. It will probably appeal to some as it is quite a novelty. Septimus F. Beck, a shaded red frilled variety, blended well with Silver Leaf Salmon. The well marked silver foliage is a welcome change.

The stand of Messrs. R. and G. Cuthbert of Southgate, Middlesex, presented a perfect feast of colour to the eye. There was a pleasing and soft mixture of the most beautiful shades of salmon, orange, rose, carmine, yellow and lemon, and many hues and tints quite indescribable. The azalea is about the only plant which can provide such a variety and wealth of coloured blooms. Apart altogether from being useful for greenhouse decoration, it is well adapted for planting out in large beds. They are all exceptionally hardy, and certainly a bed planted out in such splendid colours as Messrs. Cuthbert exhibited can scarcely be surpassed in cultivation. Seedlings and varieties of Azalea mollis were shown in abundance, such varieties as Brilliant, with trusses of a brilliant scarlet, one of the best; Chevalier de Reali, creamy white, spotted with orange; and Comte de Gomer, with a large truss, made up of rose-coloured flowers. Many splendid hybrids of A. mollis and A. sinensis, with larger flowers and colours even more brilliant than A. mollis, were also exhibited, the chief varieties being Anthony Koster, rich pure golden yellow; Nicholas Beets, deep orange; and

Digitized by Google

W. E. Gladstone, with warm orange yellow flowers. It was a fine exhibit of bloom and Messrs. Cuthbert are to be congratulated on the high standard reached in the raising of seedlings of this beautiful genus.

Most of the space in the exhibits of rock plants was taken up again by the Kabschia saxifrages.

The hybridist has been busy in this group. usually with happy results, though here and there a hybrid seemed rather vague in outline and washy in colour beside the clear cut elegance of its parents. S. Jenkinsæ, shown by Messrs. Cheal, is an improved Irvingii, the flowers, larger and of a more decided pink, are produced as freely as those of Irvingii and seem less liable to lose their colour. On the same stand Shortia galacifolia made an early appearance; it is not a common plant, but it deserves to be better known for the refinement of its large soldanella flowers showing up cleanly against the bronze leaves. Like many woodlanders it is sweetly scented.

Messrs. Prichard showed a large number of hybrid saxifrages of their own raising. Lady Beatrix Stanley, one of the most showy,

KITCHINGIA UNIFLORA WITH ITS GRACEFUL PINK BELLS.

with deep purplish-pink flowers; Amenity, a Burseriana hybrid, interesting for the terra-cotta of its stems, which somehow spreads faintly into the flowers and gives a curious warm tone to their whiteness; H. Marshall, with very pale lilac-pink flowers that open well without betraying the looseness that mars many of these hybrids.

Messrs. Tucker of Oxford showed a large group of the beautiful and free-flowering S. Burseriana sulphurea, S. Sundermanni (of Kew), a Burseriana in flower but with a much tighter, frostier rosette; S. Sundermanni (of Engler), a purplish pink Engleria hybrid; S. bursiculata, S. Franzii and many others. Messrs. Tucker also showed the uncommon Ranunculus anemonoides from the Austrian Alps, large regular flowers, like those of a flatter, neater Anemone blanda, in white, very faintly suffused with pink, radiating from a tuft of waxy, glaucous leaves. A very distinguished alpine.

The well arranged exhibit of Messrs. Cutbush included a bush of Rhodora canadensis, covered with its honeysuckle-shaped flowers in that shade of lilac pink that is all too common in its near relatives the Rhododendrons.

Messrs. Reuthe showed a pan of Tecophilæa cyanocrocus, the gentian blue Chilian "crocus," that would be very welcome in the alpine house were more of it available. The plants shown were raised from English seed, but this is produced very sparingly and re-importation of the bulbs is really needed.

Among the other exhibitors were the following:

BULBS.—Messrs. Barr and Sons.

CARNATIONS.—Messrs. Allwood Bros., C. Engelmann and Stuart Low and Co.

CROCUS.—Messrs. Carter and Co.

FORCED SHRUBS.—Messrs. L. R. Russell, Stuart Low and Co.

FRUIT.—Messrs. Westmacott and Co., Limited.

ORCHIDS.—Mr. F. J. Hanbury, F.L.S., V.M.H., Mr. H. T. Pitt, Messrs. Stuart Low and Co., and Sanders.

POLYANTHUS.—Messrs. G. A. Miller.

RHODODENDRONS.—Messrs. R. Gill and Son.

ROSES.—Messrs. Elisha J. Hicks and George Prince.

SHRUBS AND ALPINES.—Messrs. Bakers, Barr and Sons, Maxwell and Beale, Carter Page, G. Reuthe, F. K. Wood, Skelton and Kirby, Waterers, and R. W. Wallace.

VIOLETS.—Miss E. Heathcote, Baldwin Pinney and J. J. Kettle.

TOPIARY.—John Klinkert.

ARTISTS.—Maud Angell, Nellie Blacklock, Winifred M. A. Brook Marion Brown, Edith Fisher, Agnes Foreman, Champion Jones, E. D.'O. Rowe, Mrs. Henny Spenser, Winifred Walker, Alice Wilkinson, Ellen Warrington.

DRIED SPECIMENS OF PLANTS.—G. Claridge Druce, D.Sc., LL.D.

GARDEN ARCHITECTS.—R. and E. Hopkins and Percy S. Cane.

NEW & RARE PLANTS.

CYCLAMEN PERSICUM "GIANT SHELL PINK."—It is well known that C. persicum is the source of the standard florists' varieties which are of so much value for duration of bloom, variety and wealth of colour, in the greenhouse. The variety under consideration differs from the type species in its larger size and also in colour of flower. The leaves are of the usual oval shape, marbled with white and vary from 1½ins. to 3ins. across. The large, scentless flowers, made up of oblong segments of a deep shell pink in colour, are carried on erect scapes 9ins. to 1ft. high. It appears to be a free-flowering variety and should form a valuable winter-flowering plant. Award of merit. Shown by Messrs. Sutton and Sons, Reading.

PLECTRANTHUS CHIRADZULENSIS.—This might almost be termed a herb or sub-shrub, which in cultivation reaches from 2½ft. to 3ft. high. Flowering sprays were exhibited which indicate the slender and graceful habit of the plant. The leaves are toothed and somewhat resemble the common nettle. The flowers are borne in light, loose terminal panicles, varying from 6ins. to 9ins. in length. These are of a delicate, light blue in colour and have a long lip characteristic of the family to which they belong. The genus itself is closely allied to coleus. It is valuable as an ornamental herb in the greenhouse on account of its winter-flowering. Award of merit. Shown by Sir John F. Ramsden, Bealstrode Park, Gerrard's Cross, Bucks.

RHODODENDRON SUTCHUENENSE × CORNUBIA.—This is an unnamed hybrid between these two parents and combines the qualities of both exceptionally well. It carries dense heads of flowers and the long leaves, characteristic of sutchuenense, although perhaps the foliage is of a lighter green. The flowers are large, from 2ins. to 3ins. across, of a deep rose colour, spotted at the base of the lobes, which are broad. Award of merit. Shown by Colonel S. R. Clarke, C.B., Borde Hill, Cuckfield, Sussex.

LACHENALIA EXCELSIOR SEEDLING.—This is a new variety of one of the most popular and attractive subjects for the cool greenhouse. The flowers were of the favourite type, being long and bell-shaped, of a deep yellow colour tinged with red or magenta at the edges. The plants showed the merits of careful cultivation, bearing twenty to thirty flowers on the one stalk, which reached almost a foot in height. This variety easily upholds the high standard which has been reached by others of this genus. Award of merit. Shown by Messrs. Barr and Sons, Covent Garden.

CROCUS BLUE BUTTERFLY.—Dainty and graceful hardy plants from 2ins. to 2½ins. high. The flowers are of an intense light blue colour. The blue colour of the segments is set off to advantage by the brilliant orange-coloured stigma. In the interior of the segments the light blue shades into yellowish white. It is a hybrid between C. ærius and C. chrysanthus. Award of merit. Shown by Mr. H. McD. Edelsten, Hillside, Lindfield, Sussex.

KITCHINGIA UNIFLORA.—This is a comparatively new plant, having been introduced only some twenty years ago from Madagascar. A small pot was exhibited by which the general habit of the plant could be judged. The slender-growing stems are more or less prostrate and carry numerous small rounded fleshy leaves. As the specific name suggests, the stems ought to bear one flower, but this is not so, as many graceful little bells of a lovely pink colour are to be found on each stem. It appears to be an ideal plant for a cool greenhouse. Award of merit. Shown by the Director, University Botanic Gardens, Cambridge.

ORCHIDS.

AWARDS OF MERIT.

DENDROBIUM MISS FLORENCE E. KING (nobile nobilius × Artemis).—A richly coloured flower of the nobile section, the segments broadly developed, deep purplish with a crimson tint, the labellum having a central blotch of intense crimson, around which is a narrow white border, the outer margin purplish. From Mr. F. J. Hanbury, Brockhurst, East Grinstead.

LÆLIO-CATTLEYA SHEILA (L.-C. Britannia × C. Clotho).—The two large flowers of this pleasing novelty were of light rose colour, the petals well above the average size, the handsome labellum effectively crisped at the margin, the central area rich purple, and the throat yellow. The specific name is apt to be confused with L.-C. Shyla (L.-C. Pizarro × C. Octave Doin), recorded by Messrs. Stuart Low and Co. in 1922. Shown by Sir H. S. Leon, Bt., Bletchley Park, Bucks.

CYPRIPEDIUM ROBERT PATERSON VAR. BRILLIANCE (Eurybiades × Memoria F. M. Ogilvie).—A bold flower in which the dorsal sepal has a white ground, marked with confluent spots of crimson-purple, and with a suffusion of the same colour in a central vertical line. Petals very broad, and, with the labellum, yellowish heavily stained with mahogany-red. From Messrs. Flory and Black, Slough.

CYMBIDIUM REDSHANK (insigne × Redstart).—A charming new cross. The spike bore eight white flowers, the labellum lined with crimson on the side lobes and with a suffusion of similar colour on the front lobe. Shown by Lieut.-Col. Sir George Holford, K.C.V.O., Westonbirt, Tetbury, Glos.

SIMPLE GARDENING

PLANTING ROSES.

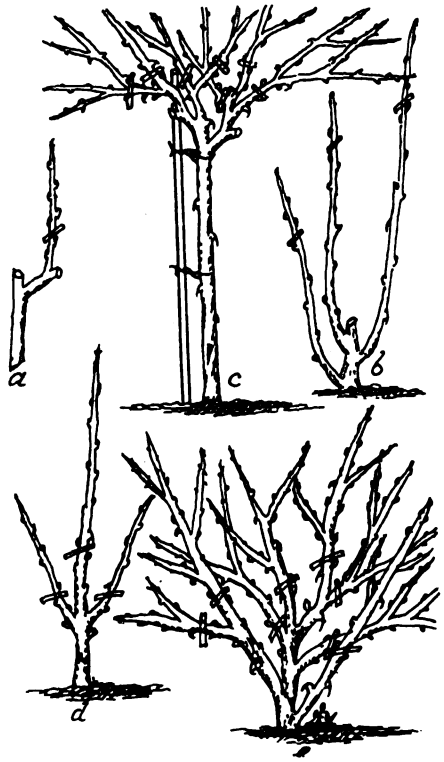
ROSES planted at this time of the year, and in soil that is fairly dry, will succeed much better than those planted in mid-winter while the ground was in a sodden state and very cold. The soil will soon be much warmer and rose trees always thrive best when their roots are in warm soil during the spring months. It was impossible to plant roses satisfactorily, during the autumn and early winter months in many parts of the country, as from north to south the ground was in a very bad state. Of course, a great deal of care must be taken, not only while doing the actual planting, but for several weeks after, so as to avoid a big check to growth after the young roots begin to grow. At all times it is very essential to success that the roots of roses and fruit trees especially, are kept in a moist state while they are out of the soil. Directly the rose trees come from the nursery immerse them for several hours in a cistern or tub filled with clear water before they are planted. The soil should be trenched, if possible, or at least very deeply dug. Naturally rich soil need not be manured, as a top-dressing of manure after planting will be sufficient in this case. But poor soil needs manure and the latter should be mixed freely with it at the time of digging, the top-dressing of half-rotted manure being applied as well, in due course.

HALF-HARDY ANNUALS.

There are many kinds of half-hardy annuals suitable for growing and flowering in a greenhouse. In this note, however, I am referring solely to those for use in the flower garden or window boxes, for filling borders or for cut flowers. There are some real gems among the plants and the work connected with their cultivation is very interesting. Generally, the first week in March is a suitable time for sowing the seeds, as the latter must be sown under glass and given protection for a time. Some cultivators will have cold frames available for the raising of seedlings. If the frames are low ones it is not absolutely necessary to use boxes as well, as the seeds may be sown in a prepared bed of soil. Now, a small frame, measuring, approximately, 4ft. 6ins. by 3ft. 6ins., would contain grand batches of seedlings; the best plan being to sow the seeds in drills. The bed of compost should be about 1ft. from the glass and contain some well rotted leaf-soil and old mortar rubble or coarse sand. Form shallow drills 4ins. apart and sow the seeds thinly in them, covering them judiciously according to the various sizes of the seeds. Example: Aster seeds should be buried nearly a quarter of an inch deep, stock seeds not quite so deeply; nasturtiums a little more than half an inch deep. Some old lime rubble is beneficial in the compost used for the seedlings when they are transplanted. This may be done in beds, in frames or in boxes. Overcrowded and weakly growth should be avoided, and due hardening of the young plants prior to planting them where they are to flower should be given.

PRUNING ROSES.

Every rose enthusiast will be anxious to start pruning his favourites, and, undoubtedly, early pruning is best if we could guarantee the weather to be just right for the resultant new shoots. Not only the weather, but the district and condition of the plants must be taken into consideration. In dealing with hybrid perpetual roses I like to cut back some of the shoots on each plant less severely than others, then, if the new growths are blackened by late frosts the extreme end may be cut off and the basal bud on each spur, if I may so name it, will grow strongly, though a little later, and ensure a supply of flowers.



Instead of cutting off the end, the blackened shoot only may be rubbed out. Then there is another point to consider when engaged in pruning work; as some varieties are less robust than others they require rather more severe cutting—the resultant shoots are stronger. Naturally strong-growing sorts should be cut less severely, the resultant new shoots are then more suitable as bloom-bearers, not being too soft and pithy. A weakly-growing plant should be cut back to two buds; a strong-growing one to four or even five buds. Hybrid tea roses are not pruned as severely as hybrid perpetuals, and rambler roses have unripe ends of shoots cut off and weakly stems removed altogether—thinning-out, as it were. The shoots should be cut off as denoted by the cross lines. The letter *a* shows how to prune a one year old shoot from the bud; *b* a rambler; *c* a standard; *d* a young hybrid perpetual, and *e* an old specimen.

PLANTING VIOLAS AND PANSIES.

Violas are planted in their flowering quarters in autumn or spring. Where the soil is light, autumn-planting is successful; but spring-planting is best in the case of heavy soils. The soil should be deeply dug and well enriched with rotted manure, leaf-soil and coarse grit. When spring planting must be done it is better to be early than late with the work so that the plants may get well established before the hot weather comes. This is a very important point where the soil in the garden is light. Before planting, closely examine the specimens and cut out, close to the base, each straggling shoot and also remove every flower bud found. The planting should be done when the soil is dry, so that it can be firmly pressed round the base of each plant with the fingers. Of course, cool positions are better than hot ones; also a fairly strong, cool loam, but not one containing stagnant water. These lovely border plants are raised from seeds sown as early as possible in the New Year, the resultant seedlings being duly transplanted in nursery beds prior to their removal to the flower garden where they will continue the supply of flowers till late in the summer.

PLANTS IN HALLS AND DWELLING ROOMS.

Few persons object to plants in the dwelling-house; even those who possess greenhouses and have them well filled with nice plants, like to have a few of them in the rooms or hall. Certainly, the majority of householders who do not possess greenhouses buy plants. Of course, some kinds of plants are not suitable for indoor culture, while others are. Skill is required in the case of growing plants in a greenhouse; it is, also, in the case of growing them indoors. The following hints will be helpful: Gas fires and lights are harmful, electric lighting is not very harmful. Bulbs may be allowed to remain in the window till their flowers have faded, then the pots should be placed at the foot of a wall outside, in a sunny position for preference. But with the exception of such plants as annuals, which may also be left to flower and die, other kinds are all the better for a change—that is, they should be taken to the greenhouse occasionally and left there for several weeks while other kinds occupy their positions in the dwelling-house. Even where there are no greenhouses many plants may be benefited by placing them in a sheltered place in the garden during the summer months. If possible, grow plants that do not require repotting while they are in the house. Do not apply strong manures to them either in a dry or liquid state; rely chiefly upon clear water—rain-water for preference. Be very careful in applying water, as over-dryness or a sodden state of the soil proves harmful. Smooth-leaved foliage plants should be sponged and syringed occasionally. Avoid all draughts.

GEORGE GARNER.

GARDENING OF THE MONTH

FLOWER GARDEN.

ANEMONES.—Plant St. Brigid and similar kinds in well prepared beds. Give good drainage. Remove protection from autumn-planted ones.

ANNUALS.—Prepare seed-beds. Thin and weed autumn-sown annuals. Sow at the end of the month in mixed borders or reserve beds any hardy annuals, such as acroclinium, calendula, clarkia, Centaurea Cyanus, eschscholtzia, eutoca, godetia, iberis, lavatera, lupins, malope, nemophila, nigella, Shirley poppies, viscaria, etc.

BULBS.—Plant in woodland when finished flowering inside.

CARNATIONS.—Plant out in border those wintered in frames.

GLADIOLI.—Remove covering from early-flowering gladioli. Plant hardy gladioli at the end of the month. Put sand at the base of the bulbs.

HERBACEOUS BORDERS.—Finish renovation and digging. Fork lightly in between plants if not already done. Take care not to injure the roots. Plant aconitum, delphiniums, lupins, herbaceous phlox, kniphofia, montbretia, etc. Complete planting by the middle of the month. Propagate by root division peonies and Anemone japonica.

LILIUMS.—Plant out those in frames when 6ins. of growth has been made. Choose a shady position. Plant L. Thunbergianum direct into border in bold groups.

PROTECTION.—Place soot and lime round base of such perennials as aconitum, delphiniums, lupins, pyrethrums, etc., to keep off slugs.

ROSES.—Lightly fork over beds. Remove protection from round base or among the branches of tea roses before the buds break. Prune hybrid perpetuals at the end of the month; in warm districts start to prune hybrid teas also. Cut back weak shoots severely, lightly prune vigorous growths. Prune weaker growing varieties more severely than robust ones. Plant if the soil is fairly dry. Mulch with half-rotted manure after planting and avoid any check after the roots begin to grow. Stake standards firmly at the time of planting.

SWEET PEAS.—At end of month sow thinly a few seeds outside, also plant out on the prepared trenches the seedlings raised last month. Stake rows before planting.

VIOLAS AND PANSIES.—Plant out those in frames.

FRAMES.—Take more cuttings of border chrysanthemums. Keep growing temperature in propagation frame. Strike cuttings of delphiniums, phlox, lupins, etc. Plant out violets when they have finished flowering. Protect with mats frames containing seedling annuals. Pinch calceolarias if growing well.

LAWNS.—Begin to mow now. Roll and sweep.

HARDY FRUIT.

APRICOTS.—Protect blossom with fish nets.

FEEDING.—Mulch newly planted trees and old trees.

FIGS.—Prune and train.

GRAFTING.—Carry out as soon as the sap begins to rise.

PEACHES AND NECTARINES.—Protect blossom with double fish nets.

PLANTING.—Complete at once. Plant loganberries and raspberries.

PESTS.—Spray apples and pears just before the buds break. Use Katakilla, a good insecticide, or a solution of 4lb. of soft soap and 3oz. of nicotine to 40 gallons of water. Hand-pick black currant bushes infected with big-bud. If attack severe, burn the bushes. Burn trees infected with silver leaf. Cut out any cankered parts of trees.

PRUNING.—Finish as soon as possible.

VEGETABLES.

ASPARAGUS.—Prepare new beds. Fork over surface of permanent beds and give a dressing of salt.

ARTICHOKES.—Finish planting Jerusalem. Clear off winter protection from globe artichokes and give a dressing of well decayed manure.

BEANS.—Sow broad and dwarf beans. Plant out broad beans raised in heat.

BEETROOT.—Sow turnip-rooted varieties in the open.

BROCCOLI.—Sow thinly in prepared seed-beds.

BRUSSEL SPROUTS.—Sow on a warm border.

CARROTS.—Sow Early Nantes and short-horn varieties. Thin as soon as possible.

LETTUCE.—Sow small quantities on a border.

LEEKS AND ONIONS.—Make a sowing at the end of the month outside. Plant out after hardening off those sown in heat.

PARSLEY.—Make sowing round edge of vegetable garden.

PEAS.—Sow early varieties in succession. Plant out at the end of the month those now hardening off in frames.

POTATOES.—Plant early varieties in warm districts.

SALSAFY.—Make a good sowing now.

SAVOYS.—Sow main crop.

SPINACH.—Make successional sowings.

TURNIPS.—Sow Early Milan varieties.

FRAMES.—Tie up lettuce to form hearts. Make a sowing of carrots and radishes. Ventilate potatoes whenever possible.

SHRUBS.

GENERAL.—Clear out any leaves or dead wood from shrubberies.

PROTECTION.—Remove when weather permits. Take away haybands from stems.

PRUNING.—Clip holly, privet, Portugal laurel, common laurel, etc. Prune after flowering by cutting back straggling branches of forsythia, chimonanthus, cydonia, hammamelis and prunus.

PLANTING.—Finish by the middle of the month. Do not transplant evergreen shrubs now. Stake and tie up newly planted shrubs. Give a mulch of well-rotted manure or peat moss litter.

RHODODENDRONS AND AZALEAS.—Give a slight surface mulch of a light leafy compost containing old mushroom manure and well decayed leaf mould.

ROCK GARDEN.

GENERAL.—Remove protection, reset stones, stir the surface. Remove any leaves killed by frost. Give a top-dressing, compost according to the requirements of the plants.

FLOWERS UNDER GLASS.

ABUTILON.—Pot on into 4in. pots.

ANNUALS.—Give final potting to spring-flowering annuals. Grow seedling hardy annuals sturdily. Keep half-hardy annuals fairly dry. Make further sowings in a cool house. Prick off seedlings in early stages.

BEDDING PLANTS.—Insert cuttings of all kinds in sandy soil in a warm house or on a hot-bed.

BOUVARDIA AND SOLANUM CAPSICASTRUM.—Pot up when ready.

CANNAS.—Start into growth. Syringe with water. Pot up when grown sufficiently.

CAMELLIAS.—Feed with soot water and liquid manure alternately once every fourteen days.

CARNATIONS.—Re-pot malmaisons into 6in. pots. Pot up struck cuttings. Never pot deeply. Keep down aphis and mildew. Feed with good fertiliser.

CHRYSANTHEMUMS.—Pinch points when plants are 6 inches high.

CINERARIAS AND PRIMULAS.—Sow seed of dwarf cineraria. Stake flowering cineraria. Sow P. stellata and P. malacoides in pans of rich compost. Place in warm position.

CYCLAMEN.—After flowering remove to frames. Keep fairly dry.

DAHLIAS.—Start another batch. Start in boxes and pot up young growths when 3ins. long.

GLOXINIAS.—Move into larger pots. Keep the atmosphere close and moist.

HIPPEASTRUMS.—Feed with guano or Clay's Fertiliser when growing well.

HYDRANGEAS.—Give autumn-struck cuttings a larger pot.

LILIUMS.—Feed moderately. Temperature 50°–55°. Fumigate regularly with nicotine compound.

PELARGONIUMS.—Pot up into 3in. pots zonals for winter flowering. Grow in cool atmosphere.

POINSETTIAS.—Give complete rest. Throw under staging and give no water.

ROSES.—Guard against mildew. Syringe with Abol or dust with sulphur to keep down this disease.

SWEET PEAS.—Stake carefully. Move into frames young plants and then plant out at the end of the month.

GENERAL.—Sponge leaves of foliage plants during wet weather to keep down scale, etc. Feed spring-flowering shrubs.

FRUITS AND VEGETABLES UNDER GLASS.

FIGS.—Thin young growths.

MELONS.—Plant on prepared beds. Tie growth up to trellis. Keep atmosphere warm and moist, but ventilate freely on warm days. Pinch points from laterals after the second leaf. Pot on young plants. Grow them rapidly.

PEACHES AND NECTARINES.—Disbud after fruit has set. Remove all growths from the front or back of the present wood. Retain the top growth and those that break at the bottom. Disbud gradually. Syringe again after flowering. Temperature 60°. Prevent a hot, dry atmosphere, which causes an attack of red spider. Thin out peaches on early varieties. Remove only a few at the first thinning.

VINES.—Tie down young shoots. Thin grapes of early varieties. Give higher temperature for flowering vines. Start vines in cold houses.

STRAWBERRIES.—Increase temperature as fruit swells. Discontinue feeding as fruit colours.

CAULIFLOWERS.—Plant out in cold frames or harden off boxes of transplanted seedlings in frames.

CUCUMBERS.—Make another sowing, using ridge varieties. Plant out on prepared beds those in 5in. pots. Syringe and damp down. Temperature, 70°–80°.

CELERIAC.—Sow in gentle heat.

CELERY.—Prick off into boxes.

DWARF BEANS.—Stake if necessary.

LEEKS AND ONIONS.—Grow near the glass. Prick off another batch.

MARROWS.—Pot on young plants. Sow another lot in 3in. pots at the end of the month.

MUSHROOMS.—Make up another bed.

PEAS.—Place boxes in cold frame.

SEAKALE.—Continue to grow a few crowns in darkness in a cool shed.

TOMATOES.—Sow outdoor varieties. Pot on other plants. Use a light compost. Leave room for top-dressing. Keep plants fairly dry. Prick off seedlings into boxes when ready.

CORRESPONDENCE

OSMANTHUS DELAVAYII.

SIR,—The ground is too wet for me to use spade or trowel, so I take up my pen, but with hesitation, for I am bold enough to criticise you, Mr. Editor, and also another high authority, but I do so very gently I hope. In one of your lucid articles recently you loudly praised Osmanthus Delavayii, and rightly so, for who could see this delightful shrub and not want to possess and grow it? But you also express some surprise and disappointment that your previous advice to grow it had not resulted in it being a more common object in gardens.

A short time ago several correspondents expressed their opinions on the use of Lonicera nitida as a hedge plant in the columns of THE GARDEN, and Sir Herbert Maxwell wrote and said, "Why grow L. nitida, why not make your hedge of O. Delavayii instead?" Now, I never see any remarks from Monreith that I do not read and grasp, for they constitute the gospel of gardeners, but when I read that, I realised more than ever the gulf between Monreith and many of us. How many of us could afford to take a couple of hundred cuttings from our osmanthus and strike them for a hedge, and how few of us would not, I fear, have joints too stiff to use the shears by the time such hedge needed clipping? We all desire protecting holly hedges 7ft. or 8ft. high round our gardens, and inner screens of neat yew to shelter our osmanthus and a hundred other treasures; we imagine groups of Viburnum fragrans, tall mezereum or a corner of desfontainea, but, Mr. Editor, these and so many choice subjects are all governed by the enemy and victor of us all, Old Father Time. The slow growth of so many of them is too often overlooked in print, in practice we soon realise it.

The other day in my garden I moved a specimen of Azalea amœna. It was 3ft. high and over 4ft. through, but my pride in it was much damped by the thought that it was no mean bush when I had previously planted it twenty-five years ago! No, sir, time is the essence of all these things, and the pen must not forget it. It all reminds me of the story of the enquirer who wrote to one of our best-known papers and asked the editor for his advice on "How to grow walnuts?" The editor, with that wisdom which is inseparable from your high calling, made the brief reply, "Get your grandfather to plant them."—ERNEST BALLARD, *Colwall.*

CROP ROTATION.

SIR,—Mr. Beckett's article on "Rotation of Crops" is an interesting one, and suggests the possibility of a series of articles on the subject. Rotation of cropping is no new thing, it has been practised from Anglo-Saxon time, and been modified to accommodate every new introduction. Experimental work carried on anywhere is founded on the Rothamsted series of field experiments, which date back to 1840, and are still being carried on and extended. Every thoughtful gardener has his own system, borrowed or worked out, to suit his own soil conditions and the plants which he has to grow in that soil. During the war there was an immense increase in the number of vegetable growers. The necessity for increasing the output of food being the principal incentive. Many of those growers found it profitable or agreeable, and have continued the practice. It is mainly among those amateur growers that the necessity for studying this practice exists. That there is a need for it is very certain. You have only to examine the gardens of agricultural labourers to see it for yourself. In those gardens potatoes after potatoes and little else is the invariable rotation, and it is this want of system that is largely responsible for perpetuating wart-disease, leaf-roll, mosaic and the other ills to which the potato plant is subject. Mr. Beckett has named four years as the minimum period for the repetition of any individual crop. For some things it might well be lengthened, unless special precautions (such as periodical liming) are taken to eliminate the risk of soil infection. As an illustration of this it is commonly accepted that a five years' rotation is too short a period to eliminate the fungus which causes club-root or finger-and-toe in turnips and other members of the cabbage family, and that is not the only trouble to which highly manured and cultivated ground is subject. It would be interesting if a series of notes on garden crop rotation could be published giving details regarding soil, rainfall, etc., as well as any reasons that may have led the cultivator to depart from common practice. I give the rotation as practised in my own garden. It is good loam (of varying depth) on a subsoil mainly gravel, and having been at one time the bed of a river the depth of soil varies considerably. Underground water can be found in almost any part by digging a few feet into the gravel. The average annual rainfall is in the neighbourhood of 28ins., though for the last two years it has been almost 36ins. My rotation is as follows: First year.—Summer brassica plants. Winter fallow. Second year.—Potatoes (early), followed by winter brassica. Third year.—Peas, beans, celery, onions, carrots and other deep-rooted vegetables. Winter fallow. Fourth year.—Strawberries planted in spring. Fifth year.—Strawberries. Sixth year.—Strawberries trenched down in autumn and followed by winter fallow. My garden lies fairly low, forming part of an alluvial flat formed by a shifting river, and is very subject to early and late white frosts, so winter catch cropping can seldom be resorted to.—WILLIAM LOW, *Balmakewan, Montrose.*

[We should be glad to receive other notes on rotation from our readers.—ED.]

ST. BRIGID ANEMONES FROM SEED.

SIR,—In your February 14th issue I was much interested in the illustration of Anemones St. Brigid sent by D. Bucknall, Co. Cork, who enquires if any of your readers have had such fine results. I have been growing St. Brigids from seed for over twenty years with very gratifying results, and I often wonder why one of our finest spring flowers is so much neglected, at least in Scotland. Possibly it is because the intending grower has started away with a hundred or two of tubers, which invariably mean a rather "blanky" bed or border and also smaller flowers. I sow the seed thinly in boxes about the second week in April in a little heat, and afterwards prick out in cold frames, allowing them about 3ins. each way, and so have good plants ready for their permanent quarters by the end of August or beginning of September. It is an advantage to get them out early so that they may get well established before frost sets in. They are not too particular as regards exposure, but if one can give them a southern or western aspect all the better. A fairly open soil enriched with some good old cow manure will suit their requirements. Allow 6ins. or 7ins. between the plants and a foot between the lines. At the present time I have a long border looking very promising without a single blank. In the first lot of plants, raised from bought-in seed, purples and blues usually predominate, but this can be remedied when selecting your flowers for seed for the following year. I usually tie a short piece of raffia round the stem of the largest and best coloured flowers and afterwards gather the seed daily when it is almost at the blowing-off stage. When the plants have finished flowering they are consigned to the rubbish heap, as I consider I have got the best of the flowers out of them.—C. GLASS, *Cardross, Dumbartonshire.*

PLANT LABELS.

SIR,—I regret that, in at least one respect, I have been the means of misleading those who honoured me by reading a volume, probably superfluous, which I added recently to the abundant literature on horticulture. It contained a recommendation of holly as excellent material for wooden plant labels, and this I thought was sure to be right, seeing that it was the last of many wrinkles given me by my old schoolfellow, the late H. J. Elwes. A large log of holly which happened to be in the woodyard was promptly sliced up into labels of various sizes. Their smooth white surface was easily inscribed with pencil without any need for paint, and in durability holly is far superior to deal; but that, alas! has proved to be its only virtue. When exposed to the weather these labels rapidly become darkly discoloured, rendering the inscription on them illegible; and a thin wash of white paint, such as suffices on deal labels, soon washes off the hard, smooth holly wood. Correspondents having complained to me about this, I can but offer a sincere apology for having misled them. I may add that the best wooden labels I have ever used are those painted green, as supplied by Messrs. W. Wood and Sons, Limited, Taplow, Bucks. The green paint takes and keeps lettering by a lead pencil better than white paint, and the colour renders them desirably inconspicuous in a border.—HERBERT MAXWELL, *Monreith.*

ACÆNAS IN NEW ZEALAND.

SIR,—We have a goodly collection of these native to New Zealand, and some are very beautiful when in bloom. A. microphylla is the gem among them, bearing globular heads of bright red bristles. I have seen masses of this up in the mountains creeping along the seldom-used stony roads with its bronzy beautiful foliage carrying hundreds of its bright red heads 2ins. above. This is the only one that does not have barbs to its spines. A. Sanguisorbæ is a very common one, with browny coloured heads and browny green foliage, dreaded by New Zealanders because of its barbed propagating habits. When the heads are ripe they are easily detached and cling to any passing object. The sheep farmers of the "Bidi Bidi," as it is locally called, usually have a race for the wool. The farmer trying to get his sheep shorn before the Bidi Bidi gets hold and spoils it, and not only spoils the wool but sometimes blinds the sheep by tangling up the wool by the eyes while they are feeding.

There are other sorts of acæna growing in spikes instead of globular heads, also brown with the usual pretty foliage. These are not so deadly and grow down to sea level. If anyone would care to try seeds of these or other New Zealand alpines, I would be pleased to give them to anyone who asks if they communicate direct with me.—(Mrs.) M. POULTON, *Shirley, Christchurch, New Zealand.*

[We trust that our readers will avail themselves of the very kind offer of our New Zealand correspondent. Once established in this country many of the New Zealand alpines (a number of which are very fine plants) should do well in this country. One of the chief difficulties in the way is the length of the journey from New Zealand to this side, but we hope that if any readers obtain seeds from Mrs. M. Poulton they will meet with success.—ED.]

NOTES FROM CONTRIBUTORS

VARIETIES OF THE BLACK CURRANT.

THE fruit planting season is now in full swing. Many factors play their part in the results obtained. Not the least important of these is a selection of suitable varieties. I am certain that every other factor will be rendered useless if an unsuitable selection is made. There are, for instance several black currant varieties which have had their day and should be withdrawn. To plant them is to plant disappointment. I have observed the behaviour of varieties of this fruit very carefully and consider the following to be quite reliable :

Boskoop Giant.—The largest black currant in cultivation. A very heavy cropper, having berries of excellent flavour. Commercial growers find Boskoop Giant valuable because the fruit travels so well. The big bud mite is rather partial to this variety, but its attack can be defeated by the removal of infected buds as soon as they are noticed.

Seabrook Black.—A very regular bearer in sheltered positions. Liable to " run off " a little in exposed places. The berries bear the shock of transport well, are of attractive appearance and possess a pleasant flavour. Seabrook Black has strong mite-resisting powers.

Black Champion.—One can truly say of this variety that it never fails. For years it has been regarded by growers all over the land as their most reliable cropper. The berries are of average size and the bushes of average cropping capacity. It is only just to say that the two varieties previously named bear heavier crops. Black Champion falls into the category of esteem because of its regularity.

Edina.—I am most favourably impressed by this comparatively new sort. It crops well and the fruit possesses all the attributes of a good black currant. The tendency to reversion is very slight and I have not observed any signs of big bud.

Laxton's Tinker.—This is a variety of recent introduction, and it is worthy of the firm whose name it bears. Prolific crops of large berries are produced, and those who pride themselves as judges of flavour pronounce it excellent. The variety makes more vigorous growth on light soil than any which have come under my observation.

Daniel's September Black.—A late variety and a good cropper. The fruit packs well and will keep for some time after removal from the bushes. I had berries of this variety last year during the first week of October. They had lost none of that piquant flavour which is so acceptable in black currants.—GEORGE F. COPLEY.

THE GIBRALTAR CANDYTUFT.

IT is the opinion of the writer that Iberis gibraltarica, the Gibraltar candytuft, is not nearly so plentiful as it was at one time. This is doubtless due to the fact that in many parts of the country it is not so hardy as is to be desired. This is extremely unfortunate, for a mass of this plant covered with its large heads of lilac flowers is a conspicuous feature of the rock garden. It will grow as much as 2ft. across, and those who know the appearance of the ordinary perennial white candytuft can form a good idea of the effect of a plant of this size covered with big heads of soft lilac flowers. It is easily raised from seeds sown and treated in the same way as those of hardier perennials, and, as a rule, small young plants stand the winter much better than large old ones. It may also be propagated by cuttings, so that those who live in what may be called " the debatable land " between severe and mild climates may be able to keep a small stock in a cold frame to replace any losses. Even in districts not generally reputed mild the writer has had plants which have survived for two or three years. It is well to lay stress upon the want of absolute hardiness, so that no one may be induced to purchase I. gibraltarica who owns a garden where the winters and springs are of a severe nature, where, certainly, the unhappy gardener would be sure to have to deplore the unwelcome demise of a pretty and otherwise valuable candytuft. A word may be added to suggest the frequent cutting back of old plants to maintain them in good condition and of a suitable size and form.—S. ARNOTT.

RHODODENDRON PRÆCOX.

THE subject of this note is one of the earliest rhododendrons to flower. In sheltered spots its delicate pale purple blossoms begin to expand in early February, but are, unfortunately, liable to be injured by frost. It is not unusual for a bush laden with opening buds to be entirely spoilt by one night's frost. R. præcox is worth a place in the cool greenhouse, where its flowers retain their full beauty for several weeks. As the photograph (taken on February 10th of shoots cut and placed indoors the day before) shows, R. præcox is an evergreen, and the flowers are produced, usually in threes, from buds clustered at the tips of the shoots. It is of hybrid origin, having been raised as the result of a cross between RR. ciliatum and dahuricum.—N. K. G.

ONE OF THE EARLIEST FLOWERING RHODODENDRONS, R. PRÆCOX.

THLASPI STYLOSUM

IT is many years since, attracted by the lure of possessing a winter-blooming dwarf candytuft which I had seen in an ardent amateur's garden, that I became the possessor of a packet of seeds of what was then known as Iberis stylosa. It has been called in later days Noccæa stylosa, and more recently it has received the designation of Thlaspi stylosum. Probably the last is correct.

It seems a quiet little plant to have acquired so many names, but so long as he receives the flower he wants the grower will generally be content to allow the botanists to settle their own disputes and will enjoy the little lilac flowers T. stylosum produces, often all through the winter, and certainly as soon as we have a few days of sunshine very early in the year. It is a tiny plant, only an inch or two high, with small, pale lilac flowers. " Not of much consequence ! " will be the verdict of the many, but its early-flowering appeals to all outdoor growers of alpine flowers.

It is easily raised from seeds, which is as well, as it is not too perennial and sometimes departs this life. Fortunately, seeds germinate well in sandy soil, and a similar soil and plenty of sun suits T. stylosum well when in the rock garden. Far from showy, it is yet highly attractive.—S. A.

CLEARING THE SOIL OF PESTS.

AS all gardeners know, numerous grubs and caterpillars that damage crops spend a good deal of their time underground. The pests may not go down to any great depth, but they are out of sight, and the only evidence of their presence is to be found in the damage that they do. I have found that a very effectual way of clearing ground of almost any grubs that lurk in the soil is as follows : Get about a quarter of a pound of soft soap, or the same amount of any ordinary washing soap will do as well. Boil up a quart of water, and in this dissolve the soap. When all trace of the soap has disappeared, add the solution to a tub containing four gallons of cold water.

Now take a watering-pot with a sprinkler attached and apply the mixture to the ground. Treat the ground in small sections, watching closely all the time. Almost at once the pests come up, and these should be collected and destroyed without delay. It is important not to give the grubs a chance to retreat below the surface again. Large numbers of wireworms and many other kinds of pests are easily captured in this simple way. It does not matter much whether there are growing plants on the ground, as the solution does no harm to foliage.—S. LEONARD BASTIN, *Bournemouth.*

SEQUOIA GIGANTEA

A FEW weeks ago I happened to mention, in talking about Osmanthus Delavayi, the difficulty of explaining a plant's popularity. My attention has been drawn to the speed with which Sequoia gigantea, or the Wellingtonia, spread through the country.

The history of the discovery of these trees is so well known that repetition would be superfluous, but the reasons that underly its immediate popularity are interesting. The first importation of seed was in 1853, by Lobb. His description of the tree, which, by the way, was not the first, caused a great sensation and there were notes about it in practically every paper in England. It is certain that no tree has ever caused such a sensation.

Lindley waxed enthusiastic over it in the *Gardeners' Chronicle*. He ends his panegyric by saying "Wellington stands as high above his contemporaries as the Californian tree above all the surrounding forests. Let it then bear henceforth the name of Wellingtonia gigantea. Emperors and kings and princes have their plants, and we must not forget to place in the highest rank among them our own great warrior." On further examination it was found that it was not a new genus, but related to Sequoia sempervirens, so the name Wellingtonia does not stand.

This was the merest whisper of a summer breeze to what followed. Pæans of praise were raised, the age and size of the trees increased almost daily, while they were found exceedingly useful in the pulpit for the sake of comparing Biblical dates. Lecturers considered its discovery as manna from Heaven. One lecturer at the time, after dilating upon the evils of the Californian gold rush and the Great Salt Lake, around which swarmed a great Mormon population, "under the rule of that licentious potentate, Mr. Brigham Young," went on to describe in most graphic terms trees of 400ft. and 500ft. in height. He said that the interior of one of these trees was of sufficient area to contain all the wives of Brigham Young and all the husbands of Lola Montes. Needless to say the lecturer discanted at length upon Biblical parallels and then ended "among great and prolonged applause." This is just a sample of what must have been almost a weekly occurrence during the winters of 1854 and 1855.

The only person who was not carried away was the famous American botanist, Asa Gray. It is true that in a lecture in 1872 he said, that "no account and no photographic representation of either species of the far-famed Sequoia trees gives any adequate impression of their singular majesty—still less of their beauty," but he threw cold water on the 4,000 and more years which was supposed to be the age of some of these giants. Later in the same lecture he said, "So far as we can judge from the actual counting of the layers of several trees, no Sequoia now alive can much overdate the Christian era."

Meanwhile, Messrs. Veitch of Chelsea and Exeter were steadily importing further consignments of seed and were advertising the plant. The first advertisement I can find is on February 25th, 1854, in which they say they "have much pleasure in stating that their seeds of the above magnificent tree are vegetating satisfactorily. They therefore hope to be able to send out well established seedling plants during the ensuing summer and autumn. They are now taking orders for them at the following prices:—For a single plant 2 guineas, for 4 plants 6 guineas." and so on. No doubt this original stock was strictly limited, because there are not many trees of this age in the country. There must have been numerous further importations, for in Messrs. Veitch's catalogue of 1867–68, they are quoted from 2s. 6d. to 42s. each, but by this time other nurserymen had received consignments of seed, for 1860–67 was about the top of the Sequoia gigantea boom. I can find no advertisement of them after 1876, nor can I hear of any trees being planted after that date. I know that at the present moment seed is entirely unobtainable, for the trees cannot be felled; while the cones are small, and, of course, at a great height, and so the seed cannot be gathered on the ground.

I had no idea what an enormous amount of interest was taken in the Sequoia until I began to look into the matter. The intense interest taken by expert and layman, and the publicity given it by all and sundry, certainly explain its popularity. The world is more sophisticated nowadays—particularly gardeners.

E. H. M. C.

THE CHARM OF THE MINIATURE DAFFODILS

BY EDWARD CAHEN.

SO MUCH HAS BEEN WRITTEN ABOUT THE HYBRIDISATION OF DAFFODILS AND THE LARGE BLOOMS THAT HAVE BEEN EVOLVED THAT THE MINIATURE SPECIES AND VARIETIES HAVE PERHAPS BEEN RELEGATED TO THE BACKGROUND.

WHAT is the chief distinction between the professional gardener and the amateur? Is it the preference for size shown by the former? The professional never seems to be satisfied till he has produced a bloom or a vegetable larger than his rival. In no other group of flowers is this more noticeable than among the daffodils. Such giant varieties as King Alfred and Madame de Graaff still hold the field as prime favourites among professional gardeners. Many amateurs and especially those who possess rock gardens, are turning their attention on the other hand to the miniature daffodils; thus opening up a field hitherto scarcely explored, where great variety of form, elegance and daintiness replace the grandeur of the larger types.

Plant hybridists, too, finding that so much has already been done to improve the larger daffodils, are beginnning to take an interest in these miniature species. By selecting suitable parents they have a vision of producing a daffodil with a closed trumpet, which will bear some resemblance to the flowers of the larger heaths.

In the ancient Greek legends we read how Persephone was picking narcissi when she was carried away by Pluto to become the Queen of the Shades. It is, therefore, not surprising to find that these charming little daffodils are for the most part to be found growing wild in many parts of Europe. The hedgerows and woods of Southern England produce a little trumpet daffodil only a few inches high which in itself is a "thing of beauty and a joy for ever."

The smallest of all the trumpet daffodils, Narcissus minimus, seldom rises more than 3ins. above the soil, but produces a trumpet of perfect shape.

NARCISSUS TRIANDRUS CALATHINUS.

Other miniature trumpets are N. minor, now very scarce; also N. nanus and Lobularis nanus, which is often sold for it, though it may be reckoned greatly inferior.

Fascinating as these tiny trumpet daffodils are they are really only miniatures of the larger trumpets, and it is not till we come to the distinctive species that we find blooms of really striking form. Take the genus Bulbocodium, for instance, the Hoop Petticoat or Medusa's Trumpet, as they are variously called in English. Several varieties are to be had, each with its own individual charm of form or colour. The large sulphur Hoop Petticoat (Bulbocodium citrinus), a native of the Pyrenees, where so many of our choice rock plants come from, is a fairy-like daffodil of a citron yellow colour. This consists almost entirely of trumpet as the perianth is reduced to the smallest dimensions. Its segments form a little star at the base of the trumpet.

Then there is the yellow Hoop Petticoat (B. conspicuus). It has flowers like those of citrinus, but of a rich golden yellow and rush-like foliage, which is very slender and graceful. This springs up soon after the bulbs are planted and grows to its full extent, some 6ins., before the buds of the little star-shaped flowers appear.

A very early-flowering variety is B. monophyllus. This is a native of North Africa and has pure paper-white flowers with bright yellow stamens. In a warm situation on the rockery, sheltered from the winds, this little gem will open its flowers soon after Christmas is past. Another group has the segments of the perianth reflexed like the flowers of a cyclamen. In this group there is much of interest. Narcissus cyclamineus, which takes its name from the close resemblance its flowers bear to those of the cyclamen, has a curious history. In French books of the early seventeenth century you will find figures of this little daffodil. It then appears to have been lost for two or three hundred years. It was discovered again by Mr. A. W. Tait of Oporto to whom we owe its re-introduction to our gardens. The flowers are of a rich yellow, the trumpet is long and so narrow that it might be said to be tubular. The segments of the perianth of a slightly greenish-yellow colour are of equal length, slender and reflexed. On the mountains of Spain and Portugal there grows another member of this family, discovered there by the late Mr. Peter Barr. In the hard gritty soil, often emerging from some fissure in the granite and slate rocks, he found Triandrus albus, with its elegant, creamy-white flowers, which have won for it the entrancing name of "Angel's Tears."

The perianth is reflexed but much broader than in cyclamineus or the bulbocodiums, and each segment has a fascinating little twist resembling the blades of an aeroplane propeller. The trumpet is slightly globular, a point which has been eagerly seized upon by the hybridist in pursuit of his vision of a heath-flowered daffodil. From this little cup protrudes the slender pistil, and often the stamens as well, in prettiest possible manner. Each stem bears two of these elegant little blossoms.

Mr. Peter Barr was also responsible for the discovery of another member of this division, Triandrus calathinus. This he found at some personal risk on the Isle of Glénan in Brittany.

Unfortunately, however, the sea has now washed away all trace of this rare daffodil from its native haunts. The flowers are produced, two or three together, in drooping clusters. The goblet-shaped crown is very prettily fluted at the edge.

Even a miniature polyanthus narcissus (caniculatus) has been discovered. This is a native of the sunny south, coming from Mentone and is on this account only for

Digitized by Google

very sheltered sunny positions on the rockery. It grows about 6ins. above the ground, bearing heads of three or four flowers with white reflexed perianth and bright golden yellow cups. This possesses the additional charm of being sweet scented. Grown in pans in the cold greenhouse the buds of many of the miniature daffodils are already showing before the turn of the year. The enthusiast thus has the prolonged pleasure of watching them swell day by day until the flowers appear.

Triandrus is particularly interesting in in this respect. At first perfectly straight, at the end of the stem the bud is pushed up until the full length, or nearly so, of the stem is attained. It then bends over and the buds begin to emerge from their protecting sheath. Slowly each one swells and turns whiter and whiter day by day until they closely resemble a small child's top or a plumb bob. Suddenly the tension on the points of the perianth enclosing the cup becomes too much for them, they spring apart, slowly reflexing and twisting until the flower attains its final form. There is, however, no necessity to grow them in pans under glass, though they lend themselves admirably to greenhouse decoration. Nearly all of them are perfectly hardy and if left to themselves when once planted in a sheltered position on the rockery they will become established and increase rapidly, well repaying the initial cost and trouble in obtaining them.

Growing so close to the ground the flowers are apt to get spoilt by the earth splashing up during a shower. It is therefore advisable to allow some close-growing evergreen plant to creep over the bulbs. They are thus protected during winter from excessive moisture and when the flowers open they are not spoiled. For this purpose many of the thymes are very suitable.

Most of the miniature daffodils, which find their way on to the market are collected from their wild haunts in the countries where they grow. Owing to their diminutive size they would never be found again were they allowed to die down. Accordingly they are lifted when in flower and it is owing to this somewhat drastic treatment that the bulbs do not always flower the first year. This also accounts for the high mortality among them.

N. CYCLAMINEUS NATURALISED IN A WOOD.

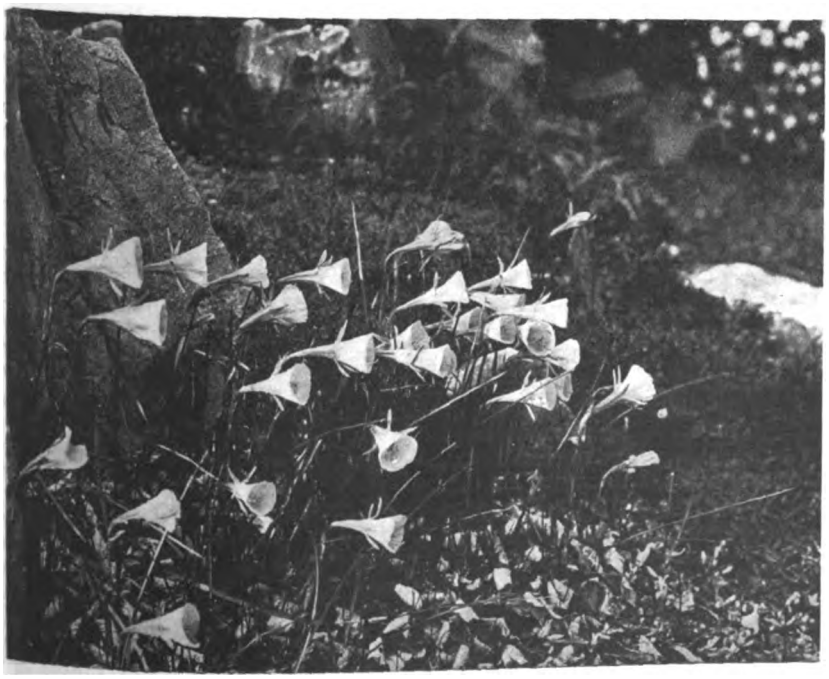
The miniature daffodils, and more especially triandrus, have proved an excellent subject for the hybridist's skill. Any number of hybrids have already been raised by crossing them with suitably chosen trumpets and other members of the narcissus family. Triandrus, indeed, is such an apt subject for hybridisation that Nature has forestalled the hybridist. A cross between triandrus and a wild trumpet daffodil has been found growing wild in Spain and has therefore received the name "Queen of Spain."

The aim of the hybridist's art, however, is twofold—to produce new forms, combining the distinctive features of both parents, and, secondly, to improve on those forms already existing.

To attain the first of these objects triandrus has chiefly been utilised as one parent. Such flowers as the jonquil and the polyanthus narcissus have been chosen as the other. In this way scent has been introduced into a strain which has hitherto had none. Perhaps one of the most beautiful of these hybrids was obtained by crossing triandrus with a polyanthus narcissus. This produces a head of from eight to a dozen pendent, pure white flowers. On this account it has been aptly named "Silver Chimes."

Turning now to the second aim of the hybridist, namely, the improvement of already existing forms, it has been found possible to increase the size of the naturally occurring flowers without depriving them of their exquisite form and daintiness.

By a suitable choice of a trumpet as one parent, and by taking cyclamineus as the other, the actual size of the flower has been increased from the somewhat inconspicuous 1¾in. of Nature's bloom to 2¼in. in the hybrid without altering the essential proportions of tube to perianth. The tube still retains its beautiful frilled edge, though it is somewhat less tubular. The perianth is slightly less reflexed than in Nature, but this rather adds to the distinction of the bloom than otherwise. The golden yellow colour is greatly improved, being more intense and richer. In the rock garden or naturalised in the woodland, colonies of these miniature daffodils are one of the charms of spring. Their slender gracefulness and dainty form



ONE OF THE HOOP PETTICOAT DAFFODILS, N. BULBOCODIUM CITRINUS.

Digitized by Google

have a fascination possessed by few other flowers, In a sheltered position they will establish themselves and increase.

Perhaps a few words should be added in regard to cost. Often this is a matter for serious consideration with the more humble amateurs of restricted means. And is it not just those who long for the rarer and more costly varieties? A comparison of the prices asked for these miniature daffodils in some half dozen catalogues reveals the fact that we are dealing with a commodity of fixed value.

Some of the Hoop Petticoat daffodils are quite cheap costing from 1s. 4d. to 1s. 9d. a dozen. Twelve bulbs of the dainty cyclamineus can be had for 4s. and the same quantity of N. minimus for a trifle more. N. nanus, however, presumably owing to its rarity, costs 1s. a bulb. Its substitute, Lobularis nanus, on the other hand is only 1s. for a dozen bulbs. "Angels' Tears" are cheap at 1s. 6d. a dozen, unless the variety calathinus is desired, when this sum must be expended for a single bulb.

ROSES AND ROSE PRUNING

SUCCESSFUL ROSE GROWING DEPENDS SO MUCH ON PRUNING THAT THIS ARTICLE MAY BE A TIMELY REMINDER OF THIS IMPORTANT GARDENING OPERATION.

IT often used to be said, partly in jest but largely in earnest, that no amateur should thin his own grapes or prune his own roses. The underlying idea being that there was a distinct danger that he would not sufficiently harden his heart to thin or prune with the necessary severity to produce a successful crop. While this remains as true in principle to-day as before, there are no serious reasons why anyone who approaches the matter in a right spirit may not prune as successfully as the most accomplished expert.

Before commencing operations, it is most essential to have clear ideas as to the nature of the types of roses that are grown and the objects in view. Generally it may be laid down that the objects of pruning roses are to obtain more and better blooms for as many seasons as possible. This suggests that the individual rose bushes are not expected to continue perpetually, and when one considers for a moment it is seen that this is so. For, while the garden rose is a shrub, it is not as other shrubs are, which, when properly planted and given ordinary attention, may be relied upon to continue as useful subjects for very many years. Ordinarily the roses in our gardens are not raised from seeds or even cuttings, but have their origin in a bud taken from a stock plant and attached to another individual. Although the pruner, naturally, has an eye to its ultimate shape, the form of the bush is, to a certain extent, of minor importance. The chief duty of a rose is to produce bloom.

The time of pruning is an important matter, and, while this will vary slightly according to local conditions, it will be found that the middle of March is the best time to prune what may be termed general utility roses—that is, those grown for garden decoration and for supplying cut bloom. Often, following a mild winter such as we have experienced this season, at the time mentioned many roses will be in leaf, and flower buds are evident. It is at such times that the inexperienced and tender-hearted amateur goes astray. It does seem a pity to destroy so much potential bloom, and there is the fear that the hard pruning of roses which are evidently full of sap will cause bleeding which must have a harmful if not deadly effect on the bushes. But no such fears need be entertained. It has been found, over and over again, that while roses which have been pruned when in almost full leaf do bleed profusely, no harm has resulted and, on the contrary, some expert growers are of the decided opinion that the loss of sap is beneficial to bushes that are necessarily too soft, in that the bleeding tends to harden them, and better blooms are the result. For a few days after having been pruned under these conditions the roses will bleed freely, but it soon ceases. If one were guided by the heart and not the head and left roses unpruned because they had grown so much by pruning time, a grave risk of loss through spring frosts would result. On the other hand, there is danger in pruning at too early a date during mild winters, because this would induce early growth of the basal buds and if these are injured by late frosts the season's bloom is lost and probably the bushes spoilt beyond recovery.

The middle of March is also a very suitable time for pruning dwarf and standard hybrid teas and perpetuals and all the Pernetiana roses. The noisette and real tea roses, which are more delicate and tender, should be left at least a fortnight later and, in cold districts, the middle of April will not be too late. The real pruning of all climbing roses should be done during late summer and autumn after they have finished flowering.

The above are the general types, and in addition there are a number of special kinds, mostly species, which often require particular treatment if they are to display their full beauty. The Banksian roses require scarcely any pruning at all. All that is needed is to cut away the old flower trusses and thin out any weakly shoots: this is best done in April, but generally they should be allowed to grow at will, especially for the first few years. Any pruning needed by the China roses should be done towards the end of March, but these must be lightly handled, and the chief pruning may well consist in thinning them a little after they have flowered. The same remarks apply to the moss roses, Penzance briars and Rosa rugosa. The last-named is most effective when given plenty of space and allowed to grow at will.

The dwarf polyantha roses, such as Mrs. W. H. Cutbush, Ellen Poulsen and Jessie, should be pruned as hard as possible at about the middle of March. They will then make robust little shoots which will continue to flower beautifully until almost Christmas. Fortune's Yellow simply needs to have the flowering shoots cut hard back to the main stems immediately their beauty is past and the resultant shoots thinned out in the following spring.

Unless there should be some special reason to the contrary all newly planted roses must be pruned as severely as possible on the first occasion after they have been planted. It may seem a cruel thing to do, and one may wonder where the plants are when the pruning is finished, but the future success of the roses depends on severity of treatment at the first pruning. This is especially necessary with climbing roses, unless they are pot-grown, and by this means they will acquire the habit of producing annually the stout basal shoots which make such a fine display during the flowering season.

With regard to the actual pruning, one must decide as to whether a comparatively few extra fine show blooms are desired or a reasonable number of flowers for general purposes. If the former is the case, the bush or standard must be reduced to fewer shoots and these must be cut closer than for the latter. But in each case the pruned shoot should be cut to a bud pointing outwards and surplus growths should be entirely removed, so that at midsummer and later none of the branches should intercross and they should be far enough apart to allow sun and air to enter the bush. When the pruning is finished there should remain a well balanced bush or standard with the shoots at. as far as possible, equal distances one from another, forming the foundation of a creditable plant which will yield the required quantity of bloom.

Although the use of secateurs is the most convenient and easy, there are objections in their way. Unless the implement is in perfect condition bruising is inevitable, and this, of course, is most harmful to the rose. Unless the shoot to be operated upon is very favourably placed it is often not possible with the secateurs to cut as closely to the bud as is advisable, and consequently a spur is left and this invariably dies back. None of these objections apply to the pruning knife, and if this is of fair size and kept sharp by far the best work is done by its use. A small pruning saw, to remove old shoots, is also needed, as also is a pair of easy-fitting gloves, while a kneeling mat is a great convenience.

A. C. BARTLETT.

NOTES FROM FLORAIRE

BY H. CORREVON.

EVERYONE who has a garden knows the popularity of blue flowers. We may know people who have blue gardens and others who search for blue flowers and leaves, so strong is the love for the colour of the sky. Specially appreciated are the gentians, blue linums and some of the boraginæous plants (omphalodes, myosotis, lithospermums, etc.), which are, generally speaking, of easy culture. We have here at Floraire a special love for lithospermum—particularly for the European species, which are the best of the blue ones. Of blue flowers there is none better than the delicious god flower (Parochetus communis), which is covered with its numerous deep blue flowers during December. It is a pea, but how beautiful it is impossible to describe.

The lithospermums can be, from a cultural point of view, divided into two groups: those which are really herbaceous and grow on flat ground, and those which are shrubby and saxatile and are better grown on walls or in crevices of rocks. The first section are plants growing in thin shade or on half-shady banks on rocky slopes. The type of this group is the beloved L. purpureo-cœruleum, a British plant which grows all over south and middle Europe and even as far east as Persia and Asterabad. It grows under banks and on bushy slopes; and thanks to its stoloniferous character, it spreads rapidly if conditions are suitable. On half-foot stems its flowers make a marvellous head of azure blue shaded with pink and purple. In the garden it likes a half-shady position, and succeeds in all light soils. L. Zollingeri is an Asiatic form of it with paler blue flowers and longer stems.

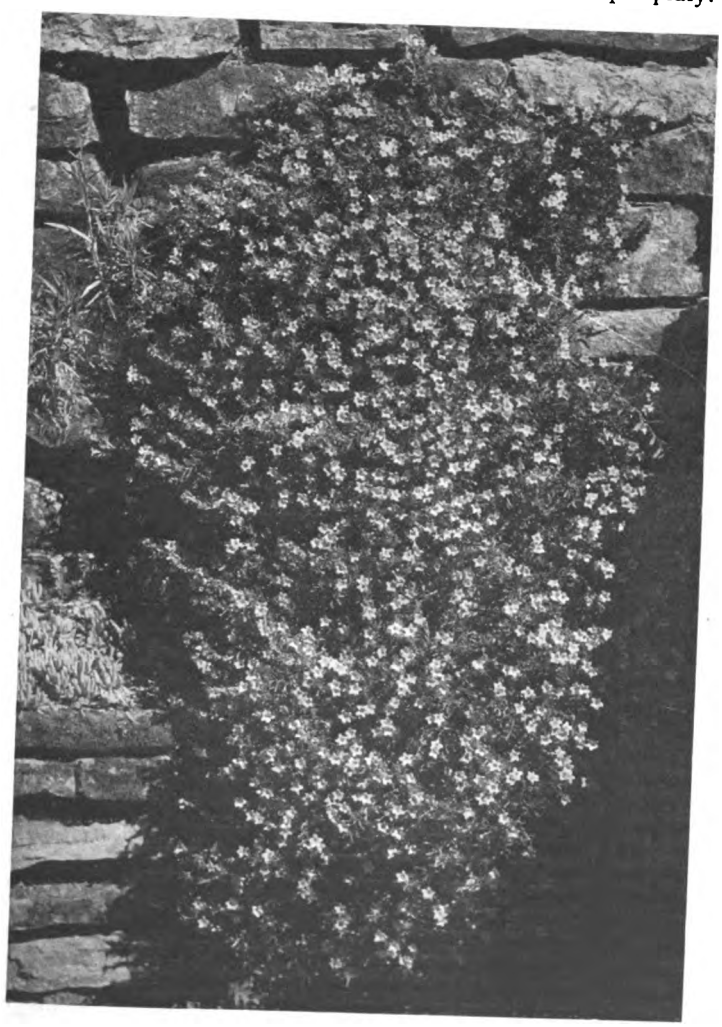
The rare and beautiful L. Gastoni (*Botanical Magazine*, t. 5926) from the western Pyrenees was introduced into gardens through Messrs. Backhouse and Son in 1870. It is seldom seen in gardens now, and is wrongly said to be of difficult growth. Such a reputation is unmerited, as it only wants limestone and a well drained soil. I saw it grown as an ordinary herbaceous border edging and flourishing there as well as the common Omphalodes verna. When planted in suitable situations it spreads through the rockery by means of its stoloniferous roots. It is a bushy plant, with broad, deep green foliage and large pure blue flowers (May to July), which are pink in the bud. The plant must be divided every three years, as it soon makes large bunches of roots. It is found on steep rocky slopes of limestone in the central and west Pyrenees from 3,000ft. to 5,000ft. altitude, always in a well drained position facing east, west or north, but never south. It grows among rank grasses (festuca, bromus, etc.).

L. prostratum is the best known of all, in England at least, where it is very popular. It is a Spanish plant which spreads north along the coast as far as Brest, growing in silicious sandy ground in half-shady situations. Under the pines of the Landes it is a beautiful sight with its large tufts of deep green foliage and its heads of azure blue flowers, which are in bloom all the summer through. Its variety Heavenly Blue is well known and more grown in England than the type. Here, we cannot grow it except in pure peat in semi-shade. Farrer, however, speaks of it as indifferent to the nature of the soil.

The saxatile and shrubby kinds are as follows: L. fruticosum, from the south-west of Europe growing around Marseilles, Aix, Nimes, Montpelier, etc., in the Pyrenees and in the whole Iberian peninsula. This is a lime-loving plant, forming a small shrub 12ins. to 14ins. high, like a poor rosemary with erect branches, furnished with narrow, thin, greyish leaves and bearing in the spring and till July many deep blue flowers; it is of a stoloniferous nature. There are fields of it near Aix-en-Provence and in the whole south-west of France. It requires shelter for the winter, at least at Floraire, and a very sunny situation.

L. graminifolium is perhaps the gem of the genus. I shall always remember the sight I had at the end of June, 1904, when I for the first time saw it on the steep path up Monte Summano in the Venezian Alps; the path was almost covered with enormous tufts of that ideal plant. It was growing along with yellow tufts of Inula ensifolia, with the deep carmine flowers of Linum viscosum, the deep red Serapias longipetala, the leathery leaves of Epimedium alpinum, etc. There the lithospermum formed such broad patches that I could not find one young plant which could be lifted. However, a friend from the town Schio sent me the same autumn a large number of seeds which came up rapidly. This is a dwarf and bushy plant, with silver-grey foliage, narrow, grass-like leaves and a stem of 6ins. to 10ins., bearing large heads of sky blue, tubular flowers, which are light pink or rose in bud. The aspect of the whole plant is charming, and when grown on a wall it is one of the best things to be seen in gardens, flowering the whole summer through and bearing thousands of flowers together. It likes a perpendicular position. Well drained soil or rock suit it well, but a wall is the best position for it. There are two hybrids of it with the L. petræum: L. intermedium (with larger, shorter leaves and deeper blue flowers) and Froebeli, which is rather dwarfer. Both seed well and come true from seed.

L. oleæfolium is a real saxatile plant, growing in a few places in the East Pyrenees between Spain and France. I have seen it on two very dry and sunny facing rocks, where it covers the stone as does Campanula Raineri in the Bergamse Alps. It creeps between the stone fissures and seems to be able to split the hardest rocks. It is very dwarf, not exceeding more than 1in. to 2ins. high, spreading by means of its thick, hard, silver-coloured stolons. The leaves are oval, thick and shining, and are as grey as those of the olive; it bears, the summer through



LARGE AND BEAUTIFUL TUFTS OF THOSPERMUM PROSTRATUM WITH MASSES OF AZURE BLUE FLOWERS.

Digitized by Google

masses of azure and rose flowers. It only requires a very sunny position on the wall or in the rockery (south aspect). It is easily propagated from seeds or cuttings.

L. petræum, (Echium, or Moltkia petræa), from Dalmatia and Greece, is a dwarf shrub not exceeding 1ft. high; it has short pale green leaves and abundant heads of blue and pink flowers, which are borne from May to July. There is a rosy pink form brought, I believe, from Greece by our Genevan botanist, E. Boissier. Same cultivation as graminifolium.

L. rosmarinifolium, from the Abruzzes and South Apennines is a delicious rosemary-like shrub with bright green leaves and large flowers of the brightest blue all the winter through. A very sunny position sheltered for the winter is necessary.

All these shrubby and saxatile lithospermums are of easy culture and reproduction, and want sun and dry positions. They are all easily germinated from seeds and can be increased by means of cuttings. With their masses of blue flowers and pale green foliage they give excellent effects in the rockery.

LITHOSPERMUM PETRÆUM - A DWARF SHRUB WHICH WILL GIVE AN EXCELLENT DISPLAY OF FLOWERS IN THE ROCK GARDEN.

SOME CULINARY HERBS WORTH CULTIVATING

IN the majority of gardens the collection of herbs rarely extends beyond the ordinary mint, parsley, sage and thyme, though many other useful plants required in the making of salads, flavouring soups, etc., may be grown to advantage. Such herbs as basil, chervil, chives, fennel, marjoram, purslane, rampion, savory, sorrel and tarragon will flourish on common soil and are easily raised from seeds or cuttings. A dry and sunny position should be chosen for the production of their fragrant qualities, and the best time for making new beds or borders is in the spring, although roots and cuttings may be planted in the autumn. Herbs, when gathered, should be laid out singly on a dry, airy, shaded site for a couple of days before exposing to sunshine. Though it is a common custom to tie them in small bunches when dried, and hang heads downwards, their flavour is best maintained by picking off the leaves and placing them, well dried, into bottles tightly corked, and storing in a dry place. The following are a few hints respecting the cultivation and uses of the various herbs:

SWEET BASIL (Annual). — Used as seasoning for soups, etc.; the leaves and tops have a strong flavour of cloves. The seed should be sown on a hot-bed in April, and the seedlings planted out in a warm border when the summer is so far advanced that there is no longer any danger from frost. The crop is generally ready for gathering in August.

CHERVIL (Annual).—Also known as sweet cicely and myrrh. A favourite old aromatic herb which, though rarely found in an amateur's garden, is very useful for salads and flavouring purposes in the same manner as parsley. If sown in May, the foliage will be ready for use in about six weeks. The seedlings should be thinned to about 6ins. apart, and for a succession of plants another sowing may be made at the beginning of July, with a third sowing about a month later. Only a small quantity of seed should be sown at once, as a few plants will provide a supply of leaves for picking. Plenty of water must be given to secure a good crop.

CHIVES (Perennial).—The properties of this herb are very similar to those of the leek and onion; the leaves are used for flavouring soups and dishes and salads. The bulbs are very useful in spring as a substitute for young onions, and, apart from their utility, chives are very ornamental, throwing up lavender-coloured blooms during the summer, giving a pretty effect and finish to bed or border edge.

FENNEL (Perennial).—The leaves of this strong smelling herb are very useful for flavouring soups, garnishing and in the making of several fish sauces, being regarded as an almost indispensable adjunct to mackerel. Sow during April and May in drills an inch deep, and from 12ins. to 15ins. apart. The plant is so easy to grow and adapted to all soils that it may be cultivated either in the herb bed or in any out of the way corner. As a rule, a bed of fennel will continue in use for years if not allowed to flower and seed. Like mint the plant can be easily forced if potted up in winter and put into moderate heat.

POT MARJORAM (Perennial). — The aromatic leaves are employed, both green and dried for stuffings and seasoning for soups. The best means of propagation is by dividing old plants in March or April, or the seed may be sown in spring or autumn, and the seedlings planted out in a sunny position, 12ins. to 15ins. apart each way.

SWEET-KNOTTED MARJORAM (Annual). —This is considered superior to the perennial variety, being of better flavour, and so easily and quickly grown that seeds sown at the beginning of April will produce plants ready for use by the end of May. Early in June it is a good plan to make another sowing; these two sowings will afford a continuous supply. The seeds should be sown very thinly in drills one foot apart, and the seedlings thinned to about 8ins. apart in the rows.

PURSLANE (Annual). — The young shoots and leaves are used in salads, soups and for pickling. Any light soil will suit it; being succulent it will even thrive in sandy soil. It requires to be sown in April, or when the danger of frost is over, and covered very slightly.

RAMPION (Annual).—The leaves and roots are used in winter salads; the roots also may take the place of radish, having a pleasant nutty flavour. The seeds should be sown at the end of May, in rather light soil, and thinly covered.

SUMMER SAVORY (Annual). — The aromatic tops are used for salads and soups, also for boiling with beans and peas, to which it imparts a nice flavour. Propagated by seed sown during April.

SORREL (Perennial).—Used to impart an acid flavour to salads. Served also as a separate dish, or mingled with spinach, and as an ingredient in soups and sauces. Grows freely in any good garden soil, and is increased by dividing the roots in spring. They should be planted in rows 15ins. to 18ins. apart, and the flower stems cut down directly they appear. Only a few leaves from each plant should be gathered at a time.

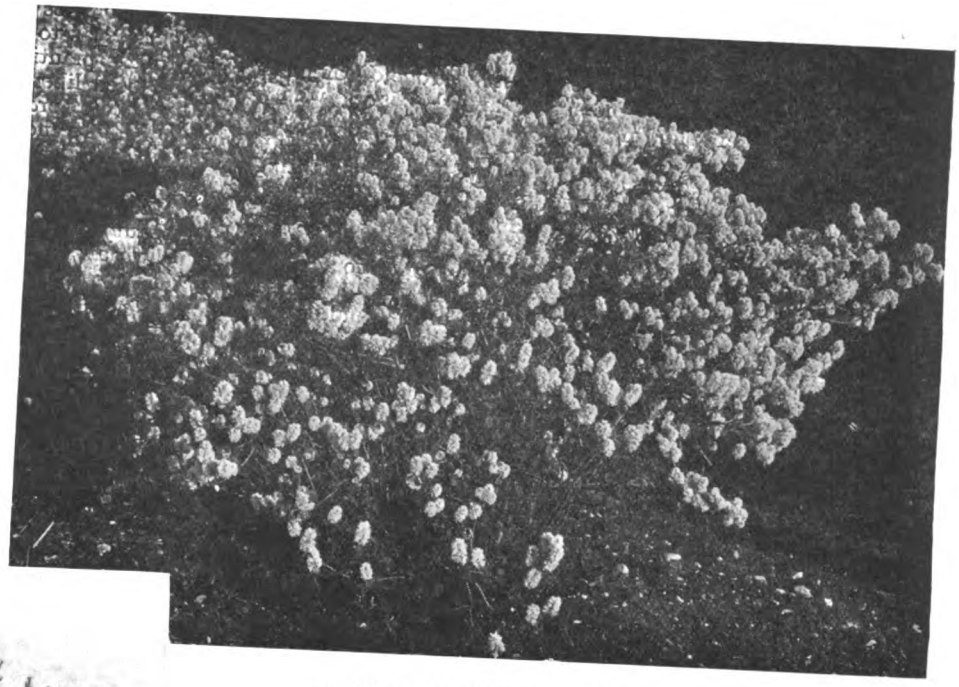
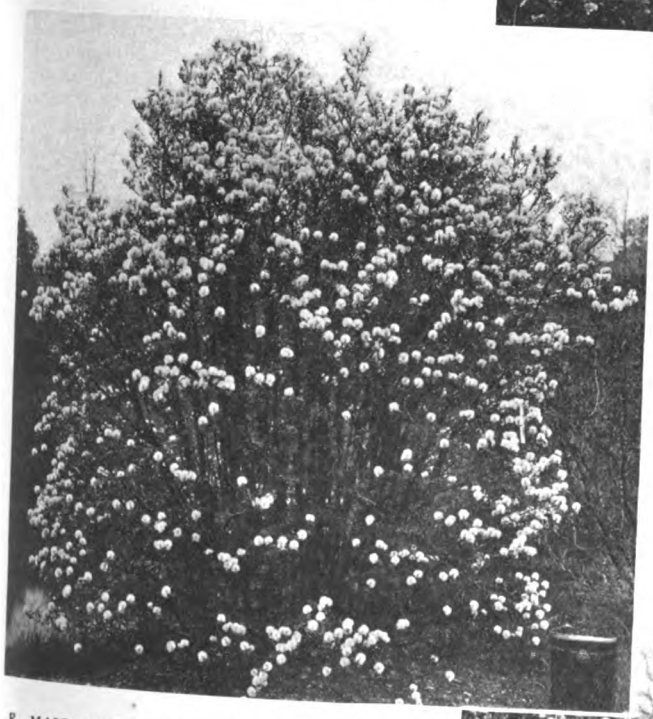
FOTHERGILLAS

WHY are the fothergillas so little known in English gardens to-day? So long ago as 1765 one species (F. Gardeni) was in cultivation in England, and in 1780 a second species, now known as F. major, was growing there. These are figured in the *Botanical Magazine* for 1810 (tt. 1341, 1342). The genus itself commemorates an old-time English worthy, one Dr. John Fothergill, who in the eighteenth century had a garden at Stratford-le-Bow famous for its collection of American plants.

Fothergillas are purely American shrubs, being native of the Alleghany Mountains and adjacent parts of the south-eastern United States. Three species are now recognised, though the differences between two of them (F. major and F. monticola) are admittedly slight. F. Gardeni, the first known, is really the poor relation of the group. All three



A COOL SITUATION SUITS F. MONTICOLA.



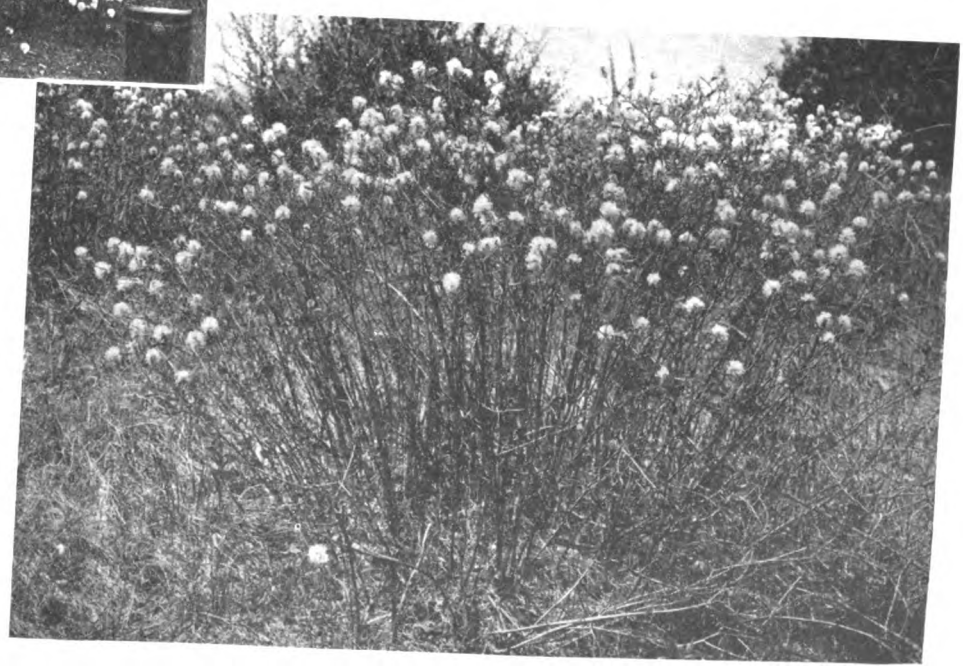
F. MAJOR, OF STURDY COMPACT HABIT.

are very hardy shrubs, sending up freely erect shoots from the base and branching plenteously form dense bushes. They are relatives of the witch hazels and resemble them closely in foliage. The flowers, however, are very different in appearance, consisting of long, erect, white stamens tipped with yellow anthers crowded together in ovoid and rounded ½in. high clusters at the ends of the innumerable naked branchlets. The whole inflorescence is fragrant and very conspicuous, resembling a bottle-brush, and quite different from that of any other hardy northern shrub. The shrubs are very free-flowering, and in the autumn the leaves assume a brilliant crimson in the case of F. Gardeni and, red orange and yellow in the other two species.

In habit F. major is a sturdy compact shrub, oval in general outline and 10ft. and more tall. F. monticola is looser, more spreading and less tall, though equally vigorous. The other species (F. Gardeni) is a more slender plant, seldom more than a yard high, with weak often lolling stems and smaller flower-clusters. In the Arnold Arboretum these Fothergillas flourish, F. major and F. monticola especially, in any soil and situation, though a sandy peaty soil and a cool situation best meet their needs. They fruit freely, but, since on ripening they violently eject their seeds, they need watching if seeds be required for propagation. They may also be increased, by cuttings of ripened wood under glass, by layering and by suckers.

Distinct in character, perfectly hardy, free-flowering, free from disease pests of any kind and with glorious autumn foliage, I herewith present their pictures, and again ask: Why are fothergillas so little known in English gardens?

E. H. WILSON.



THE MORE SLENDER FOTHERGILLA GARDENI.

Digitized by Google

PLANTING THE WATER AND BOG GARDEN

WHEN the summer is over the gardener is often appalled by the amount of renovating, remodelling and replanting that faces him during the months that vegetation is dormant. It is consoling that there is at least one department that he can leave over until the spring, and that is the waterside and bog garden planting. Indeed, had he nothing else to do, the wise gardener would wait until winter is over for this work. It is never wise to carry out this transplanting during the cold, and usually wet, days of winter. I am no advocate of mid-winter planting of anything in the garden when it can be avoided, but certainly in the water or bog garden, where the roots will lie dormant in a condition of icy saturation for many weeks, it often proves fatal. Of course, the preparation of new planting areas can be undertaken at any time during the winter, but even in this it is as well to leave those portions that are in immediate contact with the water until just before the time of planting. In such spaces the finely broken earth, and any material such as leaf-mould, peat or manure that may be incorporated with it, is likely to get sodden, and if the water rises and falls to any extent much of it may be carried away by the receding flow, whereas if left until just before the planting is done, the rapid root action will secure it against such a catastrophe.

The present article being intended as a guide as to what, rather than where and how to plant, it will be best to imagine the conditions that obtain in the majority of cases and describe the plants suitable for each position, or the various conditions it provides. Whether the water garden be small or large, stream, pond or lake, its effective treatment involves taking in as much of the area in the immediate neighbourhood as can be brought successfully into the garden picture to be created. Broadly speaking, this may be divided for planting purposes into three distinct conditions.

1. The actual water area, its depths, or shallow margins.

2. The banks close to the waterside, and the land as far back as is kept in a permanently wet condition by the percolation of water under the ground level.

3. The more distant area where the land will probably be higher, and therefore drier on the upper surface, although it almost invariably happens that it will be cool and moist underneath at about the level of the water.

The vegetation automatically divides itself up into distinct classes. There are, first, the moisture-loving trees and shrubs that thrive in any position in which they can get their roots down into the cool damp earth. Secondly, there are the plants of the herbaceous and hardy perennial class that love the lush waterside; and, thirdly, the semi-aquatic or true aquatic vegetation that will only thrive when their roots are partially or totally submerged.

In every effort of garden planting trees and shrubs are the first things to consider, and the positions for them must inevitably be decided before any other planting is arranged for. If the space at one's disposal is not too restricted, this element is negligible, but if the space is at all contracted, trees and shrubs can only be included when the utmost care is exercised as to the choice of both variety and position.

In the planting of areas round lakes or large ponds they can be used liberally, and if they are carefully disposed they are capable of producing an infinite variety of effects of colour, contour, light and shade. Always remember trees and shrubs grow, and most of them having attained their normal size are capable of completely over-shadowing groundwork planting. In waterside gardening it is absolutely imperative to plant for beauty of outline as well as cultural success. I cannot lay down any rules for attaining this, any more than an artist can give you laws of composition for picture making. Indeed, every site will present its own problems in this respect and also suggest its own solutions.

A FINE WATERSIDE TREE, THE SWAMP CYPRESS.

By far the most important trees for waterside planting are the willows. The towering blue-grey columns of the "bat" willow, Salix alba cœrulea, when the area is large enough to admit them, are valuable trees and create points that lift the scene heavenwards and make an excellent background for all dumpier trees. No waterside scene can look flat and uninteresting where one or more little groups of this form can be introduced. Another that should always be used wherever possible is S. vitellina pendula, the golden barked weeping willow. This can be planted where its slender branches trail downwards to the water surface, or in the background where it will make a foil for other plants. I think, however, it is best at the water's edge. One of its charms is its restless movement even on the stillest day, and as its graceful, slender branches sway to and fro it keeps the water surface alive with incessantly varying effects of light and shade. In winter the bark on its young growth is golden yellow. In spring the exquisite tenderness of its young greenery strikes a note that no other quite gives, and if one desires to luxuriate in a sensuous delight of pleasing colour the ground under and around it can be carpeted thickly with some blue flower, such as Muscari Heavenly Blue, Anchusa myosotidiflora or Anemone appenina.

The more upright golden willow, Salix vitellina, is also a valuable tree, and, if necessary, can be cut back hard each year. Certainly this produces a large number of young growths that give brilliant winter colour, and these "cutbacks" are very beautiful as incidents by the water's edge. Another to which the same remarks apply is the cardinal willow, Salix Britzensis, of which the bark is scarlet, and this also is a tree that attains magnificent proportions when allowed to grow naturally. There is a delightful grey-leaved willow of almost prostrate habit with silky hoary leaves that will creep down over a bank to the water's edge and send long, arching branches athwart the surface, S. sericea pendula. The warm brown of the bark is attractive for itself and gives a sense of "drawing" to the plant that is peculiarly fascinating. This willow is not used as much as it ought to be, but it should be grown as a bush, on its own roots, and not as a standard where it has to be

Digitized by Google

grafted on a stock that usually kills the scion. S. purpurea nana, a dwarf purple species, and the grey bush willow, S. rosmarinifolia, are two other forms that can be used with discretion. S. Caprea is too coarse and rampant for the average water garden, and the weeping form known as the Kilmarnock willow is a mop-headed sort of brute for many years after planting that merely disfigures the landscape. An old well grown tree of it is certainly very fine, but there are more graceful weeping forms that render it unnecessary in the garden scheme.

Taxodium distichum, the deciduous cypress, is another tree that delights in swampy ground. It ultimately attains a great height and requires room in which to spread. Not only is the fresh green of its fernlike foliage a valuable colour note, especially in its early stages of development, but the ruddy brown and gold of its autumn tint produces a wonderful effect. This is one tree that should never be omitted in waterside planting. It will, indeed, grow actually in the water, and visitors to Kew Gardens will probably remember one there with nymphæas jostling its bole, rising from about 2ft. of water. There is a pendulous form that is also quite handsome and several varieties that, although interesting, are of no particular beauty. In all, the red-brown bark is very beautiful in winter.

SPIRÆA THUNBERGII WITH BEAUTIFUL ARCHING SPRAYS.

Except in gardens where there is room and to spare few people will want to plant the common forms of alder (Alnus glutinosa, etc.), but there is one known as A. laciniata imperialis which makes a very beautiful tree. Like the deciduous cypress, it is not averse to making its roots in shallow water. Its great merit lies in its extremely rapid growth, and it is useful for giving an established appearance to a newly planted garden.

Those who admit the elders to their planting scheme will probably prefer to restrict themselves to the garden varieties of Sambucus racemosa, of which plumosa, with deeply cut leaves, and plumosa aurea, a yellow-leaved variety, are the freer growing and most popular. There is, however, a vigorous attraction in a well flowered clump of many of the other species, particularly the North American, that is in keeping with the luxuriance of growth usually attained by the waterside.

Trees of this description are also valuable during the infant stages of the garden growth, and when other and more desirable subjects have grown up sufficiently can be cut out ruthlessly.

Poplars of most species and varieties can be planted for temporary effects, but unless the space is unlimited they grow too rapidly and assume such gigantic proportions that great care must be exercised in planting them. In gardens of moderate or small proportions they should be excluded.

Just as amenable to waterside conditions, and certainly not less beautiful, are the swamp honeysuckles; indeed, nearly all the rhododendrons known in commerce as azaleas rejoice in such conditions. Of the azaleas for this purpose choose varieties of the honeysuckle or Ghent azalea liberally. The mollis × sinensis hybrids can also be used freely. Rustica flore pleno for those who like double flowers, viscosa and its hybrid azaleoides for fragrance; but the large-flowered mollis section, beautiful as they are, should only be used sparingly. There is, however, a range of colour in those I have mentioned as most suitable that should satisfy the most exacting. There is just one fact that should be remembered in planting both azaleas and rhododendrons. Both are happier if it can be arranged that the shadow of trees protects them during the brightest hours of the day. Both have the reputation of preferring peaty soil, but it has long been proved that they will succeed admirably in good loam that is open enough to allow their myriads of tiny roots free action, and which contains no lime in its composition.

SALIX VITELLINA PENDULA BY THE WATERSIDE AT HALLINGBURY.

The andromedas also enjoy the damp areas near the water ways. Under this heading I include for convenience all those shrubs usually called andromedas, although botanically they should be divided: pieris, leucothöe, cassandra, zenobia, etc. The common bog rosemary, Andromeda polifolia rosmarinifolia is a beautiful little plant. Leucothöe Catesbæi is another useful shrub if only for the winter tints in its foliage. A fine form of this is Rollinsoni, which produces young shoots of vivid colouring and white flowers. Pieris formosa and Zenobia speciosa are two more that cannot be

Digitized by Google

omitted. All these andromedas like to be planted in half shade.

The Virginian fringe tree, Chionanthus virginica, is another May-blooming white-flowered shrub that revels in quite boggy land in full sunshine. It makes a handsome shrub and is very fragrant.

The dogwoods are all shrubs that succeed in moist land. Some, such as Cornus florida, are valuable for both flower and autumn foliage; others, like Cornus alba and its varieties, are useful as foliage shrubs in the summer and for their brilliant wood in winter. It is the young wood that offers the greatest brilliance of bark, therefore the most successful method is to cut them back hard about April.

For winter berry no shrubs offer quite the same attraction as those of the cotoneasters that will grow in damp soil. The old well known Cotoneaster Simonsii is an example, but C. pannosa and C. Francheti are equally successful, although not essentially bog shrubs, and I have seen C. horizontalis growing in permanently saturated soil spreading its fan-shaped branches aglow with autumn tint and berry over the water and thriving as if it were a true water-lover.

The deutzias are also shrubs that succeed by the water-side and equally well in drier conditions. Deutzia discolor and D. scabra are perhaps the most satisfactory, but all are successful.

In positions moist, but not too wet, the beautiful enkianthus will love to dwell. E. campanulatus in particular is a wonderful shrub, either in spring when in flower or in autumn when its foliage lights up with a sunset glow. E. japonicus is scarcely less attractive, although with its white flowers it looks more like andromeda in spring. It has a wonderful autumn colour, however.

Myrica gale (sweet gale, or bog myrtle) is a native shrub, but not by any means common. With its fragrant foliage it is in the bog garden what Myrtus communis is in the other portions.

For broad background masses Spiræas Aitchisoni, ariæfolia and Lindleyana are all useful, while Thunbergii will send its slender, arching sprays of white flowers out over the water in February and light up the banks in autumn with glowing foliage tints.

Vaccinium corymbosum, the swamp blueberry, is another moisture-loving shrub that is pretty in May with its pale pinkish flowers, but it is a joy indeed in the autumn, every shade of scarlet and crimson developing in its foliage.

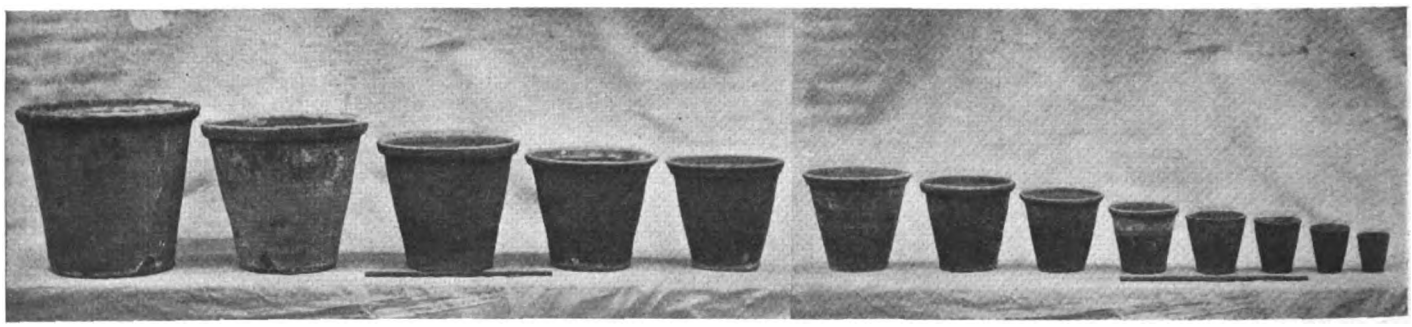
To the carpeting shrubs, such as Epigæa repens, Leiophyllum prostratum (better known as Ledum Lyoni), gaultherias and others, space scarcely allows reference, but there are a number of them that can be used in places not far removed from the waterside.

I should like to reiterate here that not *all* the shrubs I have mentioned would usually be indicated in a list for bog planting, but it must be remembered the areas near the lake or pond side are not always permanently soaked, and all I have mentioned enjoy damp conditions at their roots.

More because of their suitability of form and gracefulness of character than because they actually require wet conditions in which to grow it is necessary to mention the bamboos. Some of them it is true love moisture, practically all of them succeed in it. Most of them, whether arundinaria, bambusa or phyllostachys, will, if planted near water, spread towards rather than away from it, and will only cease their advance when they have reached its margin. GEO. DILLISTONE.

(To be continued.)

POTS AND POTTING



THE COMPLETE RANGE OF POTS, AS USED IN MODERN GARDENING.

POTTING is one of the most important of all gardening operations and it is only by some understanding of such work that one can hope to be a successful cultivator. There is no greater proof of gardening ability than that displayed by well grown pot plants, and to obtain this latter result should be the aim of all growers.

In potting, pots are of the first importance and of these there are sizes to suit all requirements—ranging from the tiny "thumb," only an inch in diameter, to the large cumbersome 20in. At the present day, pot sizes are generally indicated as so many inches in diameter; but in some parts of the country the old terms used by manufacturers are still retained, and are frequently referred to in these columns. These terms originated from the number of pots of various sizes cast from a certain quantity of clay. For example, from a certain quantity of clay sixty 3in. pots can be cast, and these are known as size 60s; from the same quantity of clay one can obtain forty-eight 5in. pots, and these are known as 48s.

The following is a list of the old sizes, with the corresponding inches in diameter. 80s, 1in. to 2in.; 60s, 3in. to 3½in.; 54s, 4in.; 48s, 5in.; 32s, 6in. to 7in.; 24s, 8in.; 16s, 9in.; 12s, 10in. to 11in.; 8s, 12in.

When pots are received from the makers they should be soaked in water for at least half an hour and allowed to become perfectly dry before using. If this is not done the dry clay will absorb the moisture from the soil to the detriment of the plant. Pots which have been previously used must be washed scrupulously clean before they are brought into service again. Not only is this a preventive to the spread of disease, but it is also necessary to ensure clean work in future pottings. It will be found that a plant which has been potted in a wet or dirty pot can only be turned out with difficulty, often at the expense of the pot and in most cases also at the expense of the plant. This is due to the roots adhering to the inside of the pot and when the soil is turned out these fibrous roots are broken off. No plant can be expected to recover from such treatment and there could be no worse example of bad workmanship.

The drainage or crocking of pots is also an important factor in good cultivation, and for this purpose potsherds provide the best material. Commence by placing a large piece, convex side up over the hole, round this place somewhat smaller pieces, then cover these over with ½in. or ¼in. chips, according to the size of pot. When crocking, the number and size of the crocks used depends on the size and the nature of the pot, and on the plant to be potted, but a few well placed pieces will prove more effective than a handful just thrown in. To prevent fine soil from being washed into the drainage, place some rough material over the crocks, such as fibrous loam or rough leaves.

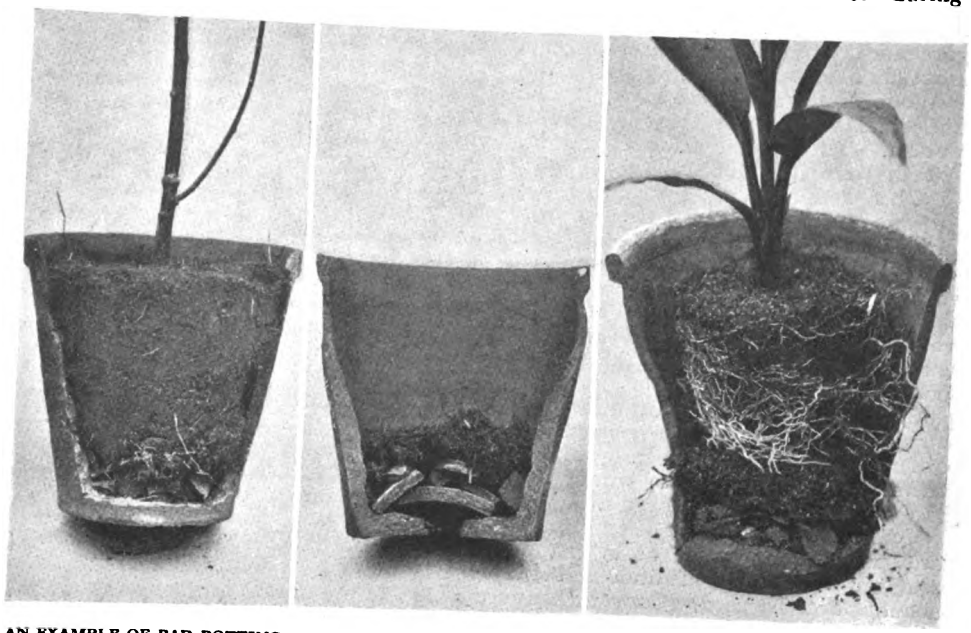
One of the most difficult operations in potting, and one which requires a great deal of care, is the potting up of rooted cuttings. In such a case we are dealing with a newly formed individual, characterised by a delicate root system and a vigorous aerial portion. This we set to nourish itself, a task which may

Digitized by Google

prove too much for it unless it is carefully nursed. Work of this kind should, if possible, be carried out in the house occupied by the cuttings, so that they may not suffer from any change in temperature. The soil should be previously prepared and the pots used just large enough to take the roots without these touching the sides. Fill about one-third of the pot with soil, then insert the cutting, holding it in position with the left hand; heap the soil up round this to rather more than the level of the pot, then, placing the first two fingers of each hand on top of the soil, raise the pot and rap it twice or thrice on the bench. This will bring about an equal firmness of soil all the way through. Pressing on the surface with the thumbs or fingers should be avoided. Cuttings which have been rooted in a close case should be placed under the same conditions for two or three days after potting, then by gradually admitting air, accustom them to the bench conditions, where, in about a week's time, they may be placed.

The successful growing of batches, such as biennials for greenhouse work, will greatly depend on the method of potting. Most of these are of rapid growth and should at no time be allowed to suffer from the lack of food material at the root. Commencing with the seedling, the best method is to prick out three or four round the rim of a 3in. pot. This ensures that the roots shall occupy the most aerated part of the soil, a condition which is beneficial to root development; also that the young plants are not totally separated from their neighbours, which is undoubtedly an advantage to plants at this stage. Once these have formed sturdy little plants with a good root system, they should be potted up singly into 3in. or 3½in., according to the size of pot it is intended to flower them in. Should this be a 7in., the following shifts are the most suitable, 3½in., 5in. and 7in. On the other hand, if they are to be placed finally in a 6in. pot, the best shifts are from 3in. to 4in. and then to 6in. In the early stages of growth the potting of such plants should be only moderately firm, with increasing firmness at each future potting, but rarely will it be necessary to use the "potting stick," the fingers and a good tap on the bench should suffice.

At no time during growth should the plants be allowed to suffer from the lack of root space. One or two plants should be examined periodically in order to ascertain the condition of the roots by turning the ball of soil out of the pot. This should be done by placing the fingers on top of the soil, with the stem of the plant between the first two, then turn the pot upside down and knock the rim on the edge of the bench. Loosened in this way the pot will lift off easily, but in doing so care should be taken not to displace the crocks. As soon as the roots show movement round the outside of the ball, then re-potting should be carried out almost immediately, unless such a condition occurs towards the end of the year when growth is almost at a standstill. It is then better to defer re-potting until growth has recommenced. Plants never do well if over-potted, that is potted on before they have developed a good root system, or it may be by giving them too big a shift. Another mistake is potting on at a bad time of the year. The effects may be somewhat overcome by careful watering, but even this seldom proves successful. The best growing months of the year are April, May and again in September, and the best time to pot is just prior to these periods, say March and towards the end of August and the beginning of September.



AN EXAMPLE OF BAD POTTING. PLACING OF THE CROCKS. RE-POTTING.

It is the usual practice to have a general re-potting of all established plants during spring, for it is necessary at this time that such plants should have some fresh material by which they can build up new growth, and being in a vigorous condition they are better able to overcome the check from root disturbance. Of all our plants perhaps the hardwoods dislike being disturbed at the root most of all, but if the work of re-potting and the treatment thereafter is carried out carefully, few losses should occur. On turning the ball out of the pot, in most cases it will be found that the roots have formed a mat round the outside and that the crocks are completely overgrown. With a sharp-pointed stick pick out the crocks, at the same time prick over the ball, removing some of the old soil and carefully disentangle the roots. Select a pot just large enough to allow about ½in. of fresh soil all the way round. In the bottom of this place sufficient soil, packing it firmly, to bring the surface of the plant ball up to the previous level, as deep planting spells death to many hard woods. Only small quantities of soil should be filled in at a time and this must be packed firmly and evenly all the way round with the "rammer." To ensure the least possible check the soil must be brought into close contact with the roots, therefore firm potting is necessary. Aim at getting the fresh soil and that of the old ball equal in firmness. On the other hand, if the soil is filled in carelessly, bad packing at the base is almost sure to occur, even to the extent of cavities, resulting in the roots in this area becoming dried and useless and, ultimately, in the death of the plant.

Most hardwoods will benefit through being potted twice during the season, and especially those which flower during spring. The best times being immediately after flowering and again at the beginning of September.

To deal with the method of potting for all kinds of plants would require more space than is available, but there are a few general principles which may prove helpful to those who are sometimes in doubt.

Most softwooded plants require to be potted less firmly than the hardwooded sorts, so also with those which have thick, fleshy roots, such as anthuriums. These should have an open compost and this only moderately firmed in the pot, while those with very fine roots, such as our heaths possess, must be potted firmly.

Orchids and other plants which produce aerial roots only require some open fibrous material which will retain moisture.

Plants should at no time be potted while in a dry condition, for future waterings will simply pass through the fresh soil, leaving the old ball dry. Neither should they be potted immediately after being watered, as a soft ball will be forced out of shape, often rising in the pot by the firming of the fresh soil. The moisture content of the potting soil and that of the plant ball should be as nearly equal as possible. Ample space must be allowed at all times for water. This should be at least ½in. to the 3in. pot, with a gradual increase as the sizes become larger.

The watering of plants or "flooding home" immediately after potting is to be strongly recommended. Not only does this settle the soil round the roots, but it brings about an even condition which is so important in reducing to a minimum the harmful effects of re-potting.

W. LAMBERTON.

THE MANURE PROBLEM—III

THE gardener is more favourably placed than the farmer in regard to many manurial substances, partly owing to the very limited supply in some cases, and further that the gardener is often able to obtain enough from his own garden or holding.

WOOD ASHES are a case in point, and the chief plant food they contain is potash. Before the salts containing potash were introduced large supplies of ashes were collected by Kentish hop growers chiefly from cottagers who largely used wood as fuel for their domestic hearths. One cannot go wrong in applying wood ashes to most soils; they are practically fool-proof and have the effect of improving the tilth of many soils. Ashes from the garden bonfire are also valuable for their potash. If wood ashes are kept for any length of time, it is necessary, in order to preserve the potash, to keep them dry. If exposed to winter rains the potash is quickly washed away.

COAL ASHES, it should be emphasised, are practically useless as a manure, and on a light or medium soil they should never be used. On very heavy, sticky soils they, perhaps, serve their purpose in making them more amenable to working, but even in this case caution should be the keynote.

SOOT is probably more generally used in gardens than any other local substance, and its merits and demerits are probably more discussed than any other fertiliser. The chief value of soot is as a manure supplying nitrogen and used as a top-dressing in spring. It further has a tendency to improve the tilth of heavy soils and is also largely used in some market-growing districts for raising the temperature of the soil. It certainly has this effect, and is useful also in checking various pests. The quality of soot varies very considerably, and the soot obtained from the home fire is usually preferable to all others. The lighter the soot the more valuable is its manurial content. It is necessary to store it in a dry place some weeks before using. It should not be mixed with lime. When this is done the ammonia escapes and the manurial value is destroyed.

POULTRY DROPPINGS.—The supply of poultry droppings has increased during recent years, and in many districts is easily obtainable in bulk. Properly used, poultry manure is a valuable asset to the gardener. It is a complete manure containing nitrogen, phosphates and potash. The best results follow by thoroughly drying the collected poultry droppings and powdering them before use. Additions of dry soil are helpful as a factor to hasten the drying. The use of poultry manure is, unfortunately, abused by many people by being thickly applied and dug into the soil in a similar manner to farmyard manure. The result is generally weak, sappy growth to all plants. It is essentially a manure for top-dressing and is useful to all crops during their growing period. A valuable liquid manure can be made by placing about a peck of poultry droppings in forty gallons of water.

SHODDY is chiefly valuable as a substance gradually releasing nitrogen for the use of plants over a prolonged period and also for supplying organic matter to the soil. Where farmyard manure is difficult to obtain, shoddy becomes doubly valuable owing to its bulky organic content; however, used alone it is not a satisfactory substitute, because it does not supply the phosphoric acid and potash as in the case of farmyard manure. Samples of shoddy vary very considerably. Cotton waste as a manure is unremunerative if it has to be purchased; it is the wool waste which contains the valuable manurial properties. It is nothing exceptional to see large quantities of pieces of old sacking and cotton rags being dug into allotments, and it appears to many people that any material which decays when dug into the soil is good from a manurial point of view. Shoddy is being used by hop and fruit growers in Kent in largely increasing quantities, probably owing to the scarcity of other organic manures.

FEATHERS.—That feathers are invaluable as a manure there can be no question, and in the case of large feathers their use also appreciably helps to maintain the physical balance of the soil. The price of feathers is often considerably lower than shoddy, and when cognisance is taken of the fact that a good sample of feathers contains as much as 16 per cent. of ammonia, it must be admitted that a case is made out for their more general use. Unfortunately, many samples of feathers contain a large quantity of dirt, and a guarantee as to their purity should always be obtained. Small feathers decay rapidly and supply a freely available source of nitrogen.

SEWAGE MANURES.—A good case has yet to be made out for these substances as a remunerative manure to purchase; however, methods of treatment are progressing, and it is probable in the near future that a satisfactory method of treatment will be developed which will produce a useful manure from these waste products.

GREEN MANURING could be practised much more generally with advantageous results to many soils. Green crops are valuable for supplying humus to soils and also preserving the plant foods as well as supplying them. Mustard is probably more used than any other crop, and on chalky soils it is undoubtedly the most useful. The one disadvantage attaching to its use is that it is necessary to sow it early in order to secure good growth for digging into soils before frosts affect it. Tares are not suitable for the light and chalky soils, but lupins are often particularly valuable. Rye is a crop which can be sown late in September and to the middle of October. It can remain all the winter and be dug into the soil in spring with good results.

FARMYARD MANURE.—To many people to discuss the use of farmyard manure appears superfluous, and as a fool-proof manure it is almost complete, but there are certain aspects which can be usefully discussed. The storage methods employed for farmyard manure are often bad ones, and when exposed to the weather the value of the manure is considerably reduced. In the case of gardens where manure cannot be used at once, it is a good plan to place the farmyard manure in a heap and case it over with a layer of about 6ins. of soil An application is beneficial to most soils, the exception being the peaty and sour soils. It is best applied to heavy soils in the autumn or winter, and the long strawy manure benefits such soils more than well decayed short manure. The latter is more useful for digging into light soils during the spring.

LIME.—Efficient manuring is impossible without the presence of lime in the soil or in the manure to be applied. Lime is a substance which benefits the plant in addition to the soil, and its presence in the soil for most crops is an indispensable condition for their successful growth and maturity. To describe all the advantages pertaining to lime would require several pages of THE GARDEN, and it is only possible just to bring its importance forward. Many artificial manures, as well as organic manures, are incapable of being utilised by plants if lime is lacking. Finger-and-toe of the cruciferæ and various insect pests are often prevented and checked by its presence. Germs useful—in fact, indispensable—to plants are encouraged by its existence. Its effect for improving the texture of soils is also well known. The few advantages are mentioned as evidence to show the necessity for lime in all soils where the common vegetable and fruit crops are grown.

H. C. ELSDON.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

NOTES FROM CONTRIBUTORS

LAYERING RHODODENDRON MUCRONULATUM.

READERS of THE GARDEN who have seen Rhododendron mucronulatum flowering this season and wish to increase their stock may be interested in the accompanying photograph, which illustrates one method by which they may successfully obtain more plants of this early-flowering rhododendron.

The plant illustrated is one of two large groups growing at Kew, and was selected for propagation on account of its very fine form, free flowering and colour. The original intention was to pot it in a large pot and stand it under glass for the purpose of obtaining soft cuttings, which form a ready means of increase: but on lifting it was found to have a huge ball of soil and the branches proved so very flexible that layering suggested itself as the best method of propagation. Cuttings would, of course, provide a greater number of plants, but these would take much longer to grow into flowering specimens.

THE PROPAGATION OF RHODODENDRON MUCRONULATUM BY LAYERING.

The plant was lifted on February 14th just after flowering and transplanted to the arboretum nursery. A few barrow-loads of prepared soil were spread round it and made level and firm. Each branch in turn was then carefully brought to ground level and pegged securely down with strong wooden pegs. After pegging they were bent abruptly upwards and tied to bamboo canes. Great care should be exercised at this point, as the branches are liable to break between the peg and the tying. It will be noticed that each branch is bent as near as possible to a point where the main stems branch out. This should always be aimed at, so that a well furnished plant is produced.

Although perhaps not necessary, the outside bark may be scraped off the larger branches on the side which is next the soil, and in doing so care should be taken to avoid cutting away the wood. This operation will assist in checking the flow of sap and promote root growth; but it is found, however, by experiment that the abrupt bend is quite sufficient for this.

The need of care in pegging down, bending and tying up each branch cannot be overemphasised. On no account should either of these operations be carried out quickly. A steady, persistent pull will successfully bring the most difficult branch into position, and in tying, a running knot is best employed. Further to ensure success, every tool that is likely to be required should be lying handy. Pegs of various sizes should be made beforehand, and strong bamboo canes selected, so that the work can be carried out expeditiously.

When all the branches had been pegged down and tied up, more prepared soil was worked round them and made firm, care being taken that every branch was covered. It will be noticed that no extra soil is put round the "collar" of the plant. This should be left as though the plant were growing naturally upright.

Finally, wet turves were packed very tightly round the soil so that during the summer the layers may be successfully watered.

The layered branches will gradually form roots and at the end of about two years will be ready for severing from the parent plant and transplanting. These operations should not be carried out at the same time, the former being done a little before the latter.

While the pegged branches are forming new plants the stock plant will send up new branches and these in turn can be pegged down after the transplanting of the first batch. This method in time will result in a large number of plants being obtained from the original stock plant.—F. P. KNIGHT.

ANEMONE PALMATA.

THIS choice windflower deserves all the praise bestowed upon it by "Sandstone" (page 95); but I have been driven to the conclusion that it is no plant for our humid west. Time after time have we placed it in the sunniest spots at our command, always with the same result—a few flowers grudgingly given in the first season after planting; then, nothing but some scattered leaves as a prelude to death.

I came to realise the reason for our disappointment in May, 1921, when journeying by motor from Lisbon to Badajos. Between Setubal and Casa Branca the track lies over a dry moor, bare and sun-baked, but very rich in wild flowers. On the highest part of this plateau, where the clay soil was cooked to the consistency of pantiles, a space of some two or three acres was densely peopled with Anemone palmata. The foliage was nearly all dried up, the flowers nearly all gone to fluffy seed: only here and there were a few belated blossoms, both yellow and white. The conditions of air and soil were far different from any that we can provide in our sloppy climate, and I have abandoned all hope of success with this charming herb. I venture to think that "Sandstone's" prescription of peat, leaf-mould and summer moisture are conditions quite alien to its requirements, for these are just what are lacking at the place I have described.—HERBERT MAXWELL, *Monreith*.

THE SPRING SATIN FLOWER (SISYRINCHIUM GRANDIFLORUM).

IT may be, as some assert, that we attribute to the earliest flowers a charm beyond that which awaits the later gifts of Flora—a perfection which they do not deserve. But we are not prepared to assent to this reservation when we think of or see the marvellous loveliness of these often fragile-looking blossoms, which, with all their slender beauty, dare the dying winter's fiercest struggles. Most of them are lovely indeed and not to be surpassed by the flowers of summer or autumn with their more mature graces. And surely no one can venture to assert that the spring satin flower, Sisyrinchium grandiflorum, is surpassed in grace or in the marvellous colouring it shows. To see it piercing through the snows of February and hanging its delightful bells of wondrous violet or purple above the snowy carpet is to witness a loveliness which gives us joy. It is, indeed, a very beautiful plant. It has long, narrow, rush-like leaves, and above these a slender yet strong stem which bears almost translucent brilliant violet blooms, bell-shaped, and pendent from the fragile-looking pedicels with a grace unsurpassed. Its white variety, S. g. album, now quite scarce, is very lovely also, yet it does not cheer us as does the violet or typical form. It is a gem of gems, and happy are they who have clumps of S. grandiflorum—and plenty of them—in their gardens.

To secure such it ought to have a cool, peaty soil, where it will increase fairly quickly. I do not advocate too frequent division, nor would I advise planting it in too dry soil.

I think it looks best in nooks of the rock garden, where, a little above the ground level, it is more effective than on the flat. The white variety shows well against dark rockwork, but the violet or violet-purple one looks finer when the rockwork is veiled with, say, a mossy saxifrage, so that the colouring of the bells may stand out against the greenery. A good mass in the border is highly attractive, however. S. grandiflorum generally flowers in February and goes on until early summer. It is thoroughly hardy, but it sometimes resents disturbance, and ought to be planted in very early autumn rather than later in the year or in spring as some do. Plants in pots can, however, be planted out at any time. By the way, those who possess an alpine house may well add the spring satin flower to the collection of alpines grown in pots as its beautiful purple or violet bells lend a distinct tone of colour to the house, which is generally lacking in bright shades at this time of the year.—S. ARNOTT.

CORRESPONDENCE

GENTIANA PYRENAICA.

SIR,—In Mr. Clarence Elliott's interesting article on this plant (page 112) it is a little surprising to read that since seen about twenty-five years ago at Backhouse's York nursery, he has "never met the plant either in gardens, conversation or books;" and that he does "not think Farrer ever grew G. pyrenaica, and I much doubt if he ever saw it, which makes his description of it in his 'English Rock Garden' all the more wonderful."

One would have thought Mr. Elliott had known Farrer well enough to realise that his "extraordinarily true and vivid" descriptions of plants were due to the fact that he *knew*, often in their native haunts, most of the plants he described, aided by his artistic and poetic temperament and wide culture. I would suggest that these very qualities would prevent him from giving a good and Farreresque description to a plant he had not seen. Moreover, Farrer briefly mentioned this plant on page 216 of "My Rock Garden," where we read: "In the same category as *bavarica* come *pyrenaica*, too, and *imbricata*, both of whom (*sic*) are beautiful, both of whom are damp-lovers, both of whom I have tried and lost so frequently that I will hurriedly pass by these skeletons in my cupboard."

And surely Farrer, a north countryman, must have seen G. pyrenaica in the York nurseries, where many years ago it was introduced to English gardeners. I take a particular interest in this plant, apart from its beauty, because early in July, 1903, I had the privilege of accompanying my friend James Backhouse to the Eastern Pyrenees, and it was from those damp pastures near Mont Louis that the stock of this lovely gentian was then replenished at York.

Looking up all that has been published in THE GARDEN these three years about the Pyrenees and gentians, and they have been both valuable and readable articles, there is one writer to whom the "doubt if he ever saw it" would seem to be more applicable! That writer says: "G. pyrenaica, when it is obtained true, is an excellent moraine plant with well rounded flowers of a rich deep blue colour, but without the startling brilliance of G. Gentianella or G. verna." The same gentians, however, vary greatly in colour, and it is possible that pyrenaica may sometimes become bluer under cultivation. Mr. Elliott's description, "an intensely brilliant violet purple," is excellent, and does more justice to the colour than my own, "a rich violet." His suggestion of a distinct relationship with the group of ornata gentians is also commendable. It must not be forgotten that G. pyrenaica is one of several good Pyrenean or French plants which miss the Alps and re-appear in the Carpathians and the Caucasus. It is satisfactory to know that a goodly supply of this remarkable and too little known gentian is striving so well at Stevenage. The last time I saw it exhibited was at the "Bath and West" Agricultural Show in Bristol a few years ago.—H. S. THOMPSON.

PLANTS AND PEOPLE.

SIR,—I read with much appreciation in your issue of February 28th a contribution on "Plants and People," by Dr. F. A. Hampton. In this paper Dr. Hampton calls attention to two interesting names suggested by the late Mr. Reginald Farrer, but expresses the opinion that as these are not official they have perhaps already passed out of use. May I point out that Mr. Farrer's suggestions have been adopted, and both species have been described. The name "Reginella" was coined by Mr. Farrer for a delicate little primrose found by him in Kansu. While it is quite correct for Dr. Hampton to say that this name has some reference to Mr. Farrer's Christian name, I believe that Mr. Farrer had in view another interpretation of the word. Obviously, it can be translated "Little Queen." Mr. Farrer's choice was no doubt conditioned by the fact that the name served thus a double purpose. The species will be found described in "Notes from the Royal Botanic Garden, Edinburgh," IX (1916), page 197, as Primula Reginella, Balf. f. et Farrer. The cypripedium which Farrer noted as having a countenance resembling that of Bardolph is described in the same publication, page 101. Readers of the journal, as well as Dr. Hampton, may be interested to know that Mr. Farrer's two happy suggestions will not pass into oblivion. —W. W. S.

ERINUS ALPINUS.

SIR,—Your contributor Mr. Markham has sent a very interesting note and illustration on this useful and beautiful alpine. Here it grows vigorously, seeding itself over the rock garden and coming up in unexpected places. To get the best effects both the white and the rose form should be grown, and I would add the other member of the family, E. hirsutus (Farrer gives E. hispanicus as the correct name). When the rose form of E. alpinus and E. hirsutus are grown together they make a charming blend in colour, especially when seen in the evening light. Position seems to matter little with me; those plants grow everywhere and are very much at home in the moraine. It may be that the damper climate of Scotland is more to the liking of those plants than the south of England, but it is surprising that a southern plant makes itself so much at home on the chilly east coast of Scotland.—WILLIAM LOW, *Montrose*.

RHODOSTACHYS.

SIR,—Much interest has been evoked by the publication of Mr. McMullen's note and photograph of the rhodostachys which flowered in his garden last December. It would seem that the genus is commoner in cultivation than is generally supposed, and the several notes which have since appeared show the value of making others acquainted with anything unusual flowering in private collections. Mr. McMullen's plant was an offset from a plant in Mr. Smyth's wonderful garden at Dalkey, and it, in turn, was supposed to be from the old plant which has grown for many years in a narrow border adjoining the succulent house at Glasnevin. The latter is labelled R. andina, hence the reason for believing Mr. McMullen's plant to be that species. It would appear, however, that Mr. Smyth's plant cannot be an offset from the Glasnevin specimen of R. andina, but was probably an unflowered pot plant of R. Pitcairniæfolia, and it is remarkable that whereas the offset has flowered with Mr. McMullen, no attempt at an inflorescence has been made by Mr. Smyth's plant, though apparently more favourably placed. Both species are comparatively hardy, given a sunny, sheltered position at the base of a wall, or elsewhere, and well drained loamy soil. The uncommon appearance of the plants, combined with the unique colouring of the flowers and surrounding leaves, especially in R. Pitcairniæfolia, invests them with very great interest to lovers of plants. A plant of equal interest and very similar in leaf arrangement is Pitcairnia spathacea (*Botanical Magazine*, 7966), which flourishes in the same border at Glasnevin. In this case, however, the inflorescence is more or less erect, forming a panicle, totalling a height of 2ft. or more. The bracts on the scape and subtending the flowers are pink, as also is the calyx; the petals, which project considerably beyond the calyx, are pale blue. Those who are interested in uncommon plants might do worse than try this pitcairnia where rhodostachys succeeds.—J. W. BESANT, *Glasnevin*.

SMALL POTATOES AS SEED.

SIR,—There is little that I can say in answer to "E. E. P." and Mr. Stuart, who both understand the position and both, I seem to think, agree with me entirely. Rogues, of course, ought to be weeded out in every garden where seed is saved, and no seed sets should be selected from a root which has all its tubers small—a suspicious mark when other plants are normal. It is always best to begin to "rogue" a crop in the sprouting trays, and yet a rogue may have correct family ties but develop undesirable attributes later on. "Rogueing," then, must continue, and another fine time to weed out bad plants is after earthing-up finally, when the haulm meets in the drill; the work of selection, indeed, goes on until the potatoes are stored in bulk. I cannot satisfy Mr. Stuart by defining reversion. A plant of any variety may not be true to its parents; if its new properties are good we have, in all probability, the birth of a new variety, but if they are inferior to the parent we have reversion of a kind. Reversion, then, may not mean a return to an absolutely ruthless state. I agree with "E. E. P." in regard to the size of seed; small sets are from 1½oz. to 2½oz., from the size of a golf ball to that of an egg, but the sets vary very much in regard to weight and size. A full-sized tuber is twice that size. By cutting it into two there is no loss, into three a distinct gain—and then there is the possibility that the tuber is likely to be a good parent. The three of us are agreed that clean, immature, *small* sets are undoubtedly fine croppers, and I think we will agree that one reason why potato culture is not at present in as healthy a condition as it ought to be (too many partially understood diseases) is because small seed sets have become an absolute fetish with some growers.—H. H. A.

SEEDS AND SEED LISTS.

SIR,—The subject of seeds and seed lists in your issue of February 7th, prompts me to enquire why it is that seeds of trees and shrubs are, to the ordinary amateur at least, practically unobtainable in this country. At all events, I have not yet succeeded in finding an English firm of seed merchants which list these items, and an enquiry to THE GARDEN some two years or so ago failed to provide any enlightenment. There must surely be many amateurs who, like myself, indulge in the fascinating pastime of tree and shrub propagation, and it has always been a mystery to me why there is apparently no English firm sufficiently enterprising to cater for this branch of horticulture. The remarks in your Editorial, on the quality of the average English seedman's goods, are unquestionably justified. But there *are* other things besides vegetables and annuals which can be raised from seed, and it seems extraordinary that for such items it should be necessary to apply to one of the Continental seedsmen, who publish comprehensive lists embracing all kinds of subjects which the English catalogue totally ignores.—ERIC F. WETTERN, *South Croydon*.

ONIONS.

SIR,—The note on Onions by "Claremont" has tempted me to write my experience with the onion fly. I have grown onions—as a hobby—on light and heavy soils, and have only had trouble on the light. The fly appeared to me to find the plant by its scent so I thought I would plant a row of Viola Maggie Mott, which is strongly scented, across the bed about every fifth row. Result: very slight attack. A light dressing of fish meal once a week was also very effective. Up to the present I have never had a red onion (Barr's Red Globe) attacked by fly. Are some varieties immune? I think the fly passes the winter in the pupal stag eand hatches out in the spring. If onion-growing could be given up for one season only, over a wide area, I firmly believe that district would be free from the fly for a number of years. I expect some of your famous contributors will smile at an amateur's methods, but I dislike being beaten by a fly.—C. LACEY, *Wimbledon.*

SIR.—"Claremont" need not have had any difficulty in ripening his onion bulbs had he dried them in a slow oven or over a fire after they came to maturity. I find the simplest plan in ripening onions is to lift the bulbs slightly, towards the end of August and again early in September, with a digging fork, and when the leaves commence to turn brown, pull up and bunch loosely together and ripen off out of doors as far as possible; then place them for a few days in a slow oven until the outer scale leaves become brittle, when they can be stored in a cool outhouse where a good circulation of air passes freely among the bulbs.

My experience with onion fly is that the eggs are laid under the bulbs, not among the leaves, and when the maggots hatch out they commence to feed and eat their way to the centre of the young bulbs and cause decay. Deep planting in spring is very effective in checking the ravages of this pest.

"Claremont" asks the question, "Is it possible for the larva of the onion fly to lie dormant in the soil from one year to another and then awaken to activity?" I am afraid the larva—or, to be correct, the maggots—do not pass the winter as such. The metamorphosis of the onion fly is complete: that is—fly, egg, maggot and pupa.

The maggot hatches from the egg and eats greedily for some time, and when full-fed it becomes a pupa inside a brown case, usually in the soil where the onions had been growing and there remains all winter; in spring the fly emerges from the pupa.—GEORGE STUART, *Edinburgh.*

PLANT NOMENCLATURE.

NAMES ENDING IN "I" OR "II."

SIR,—This matter has been decided officially by the International Congress of Botanical Nomenclature held at Brussels in 1910, and is as follows:

When a specific name is taken from the name of a man, it is formed in the following way:

(*a*) When the name ends in a vowel, the letter "i" is added (thus, "Glazioui," from Glaziou; "Bureaui" from Bureau), except when the name ends in "a," when "e" is added (thus, "Balansæ," from Balansa).

(*b*) When the name ends in a consonant, the letters "ii" are added (thus, "Magnusii," from Magnus; "Ramondii," from Ramond), except when the word ends in "er," when "i" is added ("Kerneri," from Kerner).

(*c*) Syllables which are not modified by these endings retain their original spelling, even in the case of the consonants "k" and "w" or groupings of vowels which are not used in classic Latin. Letters foreign to the Latin of botanists should be transcribed, and diacritic signs suppressed. The German ö, ä, ü, become oe, ae, ue; the French é, ê and è become, in general, e.

(*d*) When specific names taken from the name of a person have an adjectival form a similar plan is adopted (Geranium Robertianum, Verbena Hassleriana, etc.).—EDWARD A. BUNYARD.

SNAILS AND SLUGS.

SIR,—For many years now I have used ducks as slug catchers, and find them far the most pleasant and economical method. I agree with Mr. Spragge (page 94) that they should be of one of the light breeds, or they will do quite as much harm as good, and I myself have Indian Runners. But the most valuable period of a duck's life as regards slug-eating is from about the second to the ninth week, when it will consume hundreds in a day, and at that age never touches green food, unlike a chicken, which is largely vegetarian. I think anyone would find it worth while to hatch a sitting or purchase some young ducklings, and if of the Aylesbury or other large breed, they can generally be easily disposed of at two or three months old.—E. M. LUPTON. *Leeds.*

SIR.—I should like to add my testimony to the efficiency of alum as a slug and snail destroyer, as advocated by your correspondent, Mr. Richardson.

I have two large clumps of Iris stylosa, and when they commence to bloom in November, nearly every one of the succulent young stems have been hitherto eaten off by slugs; but since spreading some powdered alum round them, and also in the centre, every bloom has been perfect all through the winter. It also seems to have a very lasting effect, as I have only made two applications in three months, notwithstanding the heavy rains we have had all through the winter, whereas the soot, salt, etc., which I formerly used had to be frequently renewed. I have also tried it with polyanthus and primrose on an old garden wall and rockery which are infested with slugs and snails, with the same beneficent result; but care should be taken to put the alum only round the stems, as I find that, if sprinkled in the foliage, it turns it yellow.

I see that in experiments made at Wisley by the R.H.S. in the destruction of slugs, etc. (R.H.S. Journal, July, 1924), they also advocate the use of sulphate of aluminium, which is alum, mixed with a saturated solution of lime in water, which I intend to try later on for delphiniums, dahlias, etc.—G. ANSDELL *Dinton.*

SIR,—Mr. F. C. King's note in your issue for January 31st, page 65, anent snails and slugs is not only interesting, but verging on comic, and seems all but incredible. Fifteen thousand slugs destroyed per day, or, taken at the same rate, 210,000 in a fortnight's work, is truly astounding. It seems such a Utopian spot for the propagation of this slug that would it not be worth his while, seriously considering the cultivation of the edible snail and supplying the Paris market? Personally, I think I suffer from every conceivable garden vermin except the snail, so cannot speak from experience, but ducklings seem the most likely cure under the circumstances—and what ducklings they would be! A great number of birds abound in my neighbourhood, and doubtless they take a considerable toll, in part payment at least for other damage done. Could Mr. King not encourage them in larger numbers?

It would be interesting and helpful to know the nature of the lands which abound in this snail-tormented spot. Could the ground not be left fallow for a year and so starve the vermin out, and if not too large an enclosure an edging of zinc, such as old roof ridges, would, I fancy, keep the ground clear from the pests in the future? Snails, somehow, cannot or will not cross zinc. Mr. King has my sincere sympathy, but there is really something comic in the situation and the feeling of forlorn hope mixed with not a little anger in his letter. His earnest desire and efforts in their destruction, however, cannot but be admired.—FORMAKIN, *Renfrewshire.*

SIR,—In connection with the destruction of slugs I would like to give another remedy which from personal experience I have found to give excellent results. I refer to the value of a waste product, namely, spent carbide from the pans of an acetylene gas plant. My first impressions of its value were many years ago, at Barrow-in-Furness, when I had the option of some loads of spent carbide for some footpaths. To my surprise, after being down on the path for one night I found that earthworms of all sizes were killed in great quantity. This gave me a clue, and knowing that worms, slugs and snails were all soft-fleshed pests, I experimented further and found that the least contact of each of these pests with the carbide was sufficient to frizzle them and destroy. Before my present master removed from Derbyshire into Durham, we had a carbide gas plant, and all spent carbide I used for footpaths. The carbide acted as a pest-killer, and also as a weed-killer. Not only has it the foregoing uses, but is too a soil steriliser for scab and rust, and slug-eaten potatoes. I gave a farmer many loads to work into a piece of old worn-out ground; this he ploughed in in the autumn, with the result that in the following season he had the most beautiful clean root crops. Like soot, lime or salt, the dry powdered carbide, which is so very valuable to have in tins for use at any time, is minimised in its effectiveness if saturated with rain.—W. H. LUCAS, *The Manor Gardens, Hurworth-on-Tees.*

IVY AS AN EDGING.

SIR,—Ivy makes a unique and attractive edging to the shrubbery, the lawn and occasionally to a selected flower border. The rooted cuttings (cuttings may easily be rooted for this purpose) are planted in line and then pinned down in freshly dug soil which is in good heart, and all subsequent growths for a year or two are pinned closely to the ground in a similar way. After this the shoots are pinned down loosely for a year or two, and finally all that is necessary is to weave new shoots under those already pinned in position.

The ivy is fairly slow in growth, but in time it makes a lovely billow of delightful green. The leaves should be clipped off every March, and they will soon come up again delightfully fresh. We have also seen the golden and smaller-leaved kinds used as edgings, but we think the strong large-leaved Irish ivy better than any.—LANARKSHIRE.

IONOPSIDIUM ACAULE.

SIR.—I notice that in your issue of February 14th you mention among "the more uncommon annuals" Ionopsidium acaule. It certainly should be more grown, as it is most useful as a groundwork plant. We sowed it here round the wide stone base of a statue in full sun, and apparently in gravel, although some good soil had been put under the base. It bloomed profusely in June and July, and then sowed itself, so that there was a new and larger crop by October, which has been in full bloom ever since, such frosts as we had not affecting either leaf or flower.—H. AVRAY TIPPING, *Middlesex.*

EXCHANGE.

SIR,—I shall be pleased to exchange three good plants of Saxifraga granulata flore plena for three plants of Phlox canadensis Laphami.—O. WILSON, *The Gardens, Arthington Hall, Leeds.*

SIMPLE GARDENING

PREPARING GROUND FOR LAWN GRASS SEED.

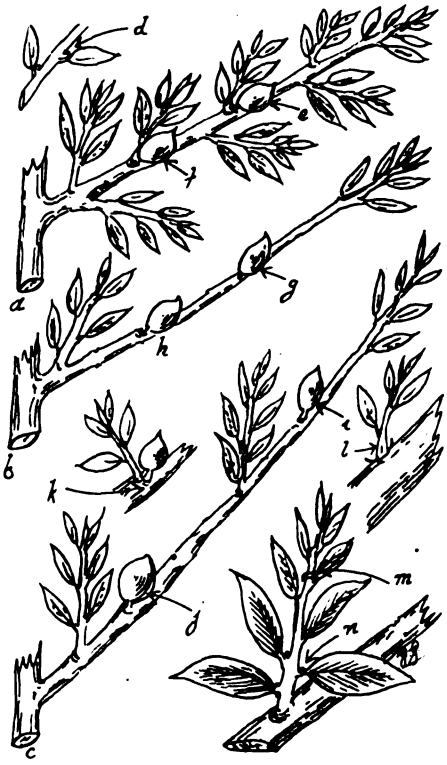
IN the southern counties grass seeds should be sown about two weeks earlier than is advisable in the northern. The soil is warmer and drier generally, and, consequently, easier to prepare than in wetter and colder parts. It is well, too, to get the resultant seedling grasses strong and well established before the hot days of summer come. Soils in some situations do not require much preparation—those that are free from large stones, coarse weeds and other foreign matter; also, those that are level or nearly so. A dead level is not advisable, as water may lodge there too long during a rainy winter; it is only safe to have a quite level lawn in places where the ground is naturally very sandy. A lawn the size of a tennis court should be about 3ins. to 4ins. lower at one end or side than the opposite. Levelling sloping ground is always tedious work if it is done thoroughly. The top 9ins. of soil should be taken off and placed conveniently, then the soil of the higher half should be transferred to the lower, and the subsoil of the higher half forked up, well broken and covered with a thin layer of rich compost. The 9ins. of good surface soil first removed should be replaced evenly over the whole; thus all parts will be of equal richness or nearly so. This is also the best opportunity for thoroughly cleaning the soil.

RE-POTTING CHRYSANTHEMUMS.

It does not matter whether the plants are intended to bear large blooms for exhibition, for groups or for cut flowers, it is a mistake to allow the young specimens to remain very long in the small pots. These plants that have received a check at this stage of their growth show it later on, its effect being to cause a thinness of stem just above the soil in the pot. Subsequent re-pottings have improved the general condition of each plant and this is shown in the greater thickness of the main stem from 6in. and upwards above the soil level. It is a mistake to re-pot all the young plants on the same date as some root more freely than others and these should be picked out and dealt with first, so it means that some of the plants will need attention in this matter every week, where large batches of them are grown, till the final potting is finished. Good fibrous loam, two thrids, leaf-soil and old mortar rubble one third, form a suitable compost. A small quantity of rotted manure, horse for preference, and bone meal may be added to the mixture with beneficial results.

DISBUDDING PEACHES AND NECTARINES.

As regards general treatment these are alike, practically. The only difference—a very small one—is that nectarines will mature more fruits than peaches without any detriment to the tree. As a general guide, one peach per square foot should be left to mature and one nectarine to every square measuring 9ins. on each side, respectively. Where a tree is cropped equally all over it, there is no difficulty in so leaving the fruits; but some trees bear more young fruits on the upper than on the lower portion. In a case of this kind the right thing to do is to ascertain the number of square feet covered by the branches and so leave the required number of fruits on the peach and nectarine, respectively. I am referring to trees in a perfectly healthy state. Those not quite robust should not be cropped as heavily. On the other hand, it is sometimes desirable to crop very vigorous young specimens more heavily. The work of disbudding and thinning-out of young fruits should be done gradually, not all in one day. The final thinning of the fruits is done after the



stoning stage. When removing the young shoots care must be taken not to loosen any young fruits that are to be retained. *a* shows a shoot before disbudding; *b*, the same branch disbudded; *c*, a longer branch disbudded. The letter *d* shows buds that will bear fruits next year; *e*, a fruit on a short branch, to be removed; *f*, one to be retained; *g*, the fruit removed; *h*, the stronger one to be retained. On a longer branch, *i* and *j* show two fruits both to be retained, also an extra young shoot; *k* shows base of fruit that must not be loosened; *l*, a young shoot on old wood, to be removed; some shoots, *m*, must be stopped; the basal buds, *n*, often bear fine fruits the following year.

PRUNING BLACK, WHITE AND RED CURRANTS, AND GOOSEBERRIES.

Although these useful fruit bushes are grown in almost every fruit garden throughout the country, there is still to be found badly and even wrongly-pruned specimens in every district. The black currant bush bears the finest fruits on the young wood and the most promising bushes are those that resemble, after pruning, healthy clumps of thinned-out willows. The correct pruning consists of the thinning-out of the oldest branches and the retention of the youngest. At the base of many of the older branches small conical-shaped pink buds may be seen. If, when pruned, a few of these buds are retained, they will, in a year's time, become strong shoots with plenty of fruit buds on them. The second year these will be the fruit-bearing branches. Many strong stems grow directly through the soil and these are good shoots to retain. When cuttings are inserted the basal buds are left intact, but these are removed in the case of red and white currants and gooseberries. Red and white currants should have leaders shortened where extension of branch is desirable, and the young shoots growing from spurs freely cut back to within three or four buds. Gooseberries bear fruit on both young and old wood. The centres of the bushes should be kept open and all side shoots that are pruned should be cut back to a bud pointing upward to ensure more upright growing shoots each year.

SOWING SWEET PEAS IN OPEN BORDERS.

For early use—at home and for exhibition—the best flowers are those that are grown on plants raised in the autumn. All lovers of these charming flowers do not sow the seeds in the autumn, nor under glass in the spring, but in the open border. With the exception of pure sandy soils the ground, generally, has not been fit to dig or fork up till quite recently. Having decided as to the position for the rows or clumps, first clear away all surface weeds and rubbish, dry it and then convert it to ashes by burning in a slow fire. Keep these and other ashes dry for use in the pea trenches. Then make the surface black with soot, deeply dig the ground evenly all over. If possible open the trenches due north and south. Clumps should be at least 5ft. apart. Open the trenches 18ins. wide, 1ft. deep, removing the soil to this depth and placing it at the side of each trench. With the bottom foot of soil mix very freely rotted manure—horse manure for heavy, cow or pig manure for light soils. Failing these, use Wakeley's hop manure, which is an excellent substitute, also, old hot-bed manure and half-decayed leaf-soil if obtainable. These additions will fill the trench to within 6ins. of the top. A 3in. potful of dry fowl manure to each lined yard of trench will be highly beneficial if it is reduced to a powder and mixed with the soil. Drop the seeds 9ins. apart in a zig-zag line and cover them 1in. deep with fine soil. The soil left at the side of each trench will be useful for top-dressing mixed with super-phosphate, later in the summer.

SPRINGTIME

EVEN in the most squalid of springs there is something to admire in flower, and no spring, however harsh and inclement it may be, is so devastating that it will remove all the blossom which pleases us year after year. The other day a few friends and I voted as to what flowering trees and shrubs we should grow in our gardens supposing that we were limited to six kinds. The only plant which everyone agreed was indispensable was a cherry of sorts. Several varieties were mentioned, among them Prunus Conradini and the ordinary double English cherry, but as long as it was a cherry we waived the question of variety.

I think that most gardeners would agree with us over this, for the cherry, probably more than any other tree or shrub, is symbolical of springtime, and that is a time of year when we like to be warned that summer and flowering time are approaching. Covered with masses of beautiful white to pink flowers standing out from their black sombre coloured and funereal branches, characteristically knotted and gnarled, they present a picture in our mind's eye that is rarely if ever forgotten. Not only does it gladden our hearts and create a warmth of affection for the trees, but it signifies an intention on the part of Mother Earth to fulfil her share in making provision for the future. Although the cherry has spread throughout the world, yet there is something about it that personifies an English orchard or an English home. And what could be more graceful! The trees in the illustration below, smothered in blossom and with a grace of form that cannot be improved upon, are growing in an ordinary orchard. They are not grown for ornament, and yet I doubt if any ornamental plant can excel them in beauty.

A SELECTION of PANSIES and VIOLAS

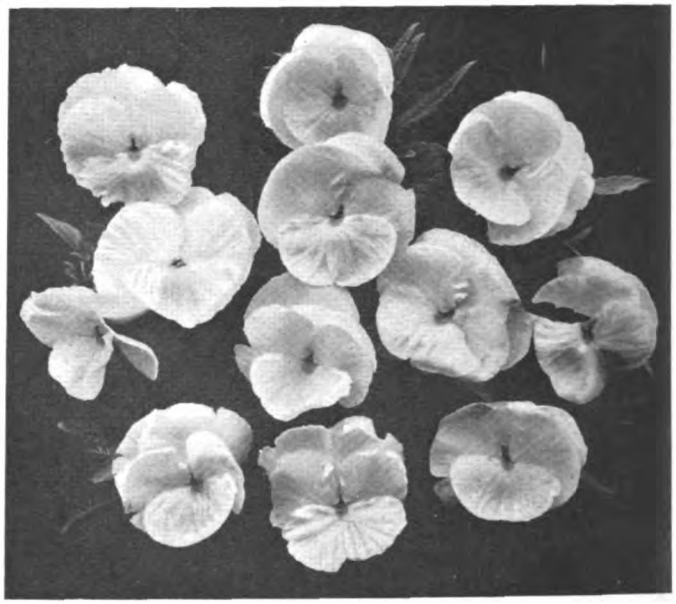
THERE seems to be a revival of interest in the culture of these pretty and useful little flowers. They appeal strongly to the town or suburban gardener who finds some difficulty in obtaining the best results from more exacting floral subjects. In the smallest plot, even if it lies within the smoke zone of a big city, pansies and violas can be grown.

Where conditions are more favourable they not only thrive but give a continuous display of bloom from early spring until the frosts come. A rich medium loam suits them best, and in those parts of the country where the climate is very temperate and rainfall above normal it is quite an easy matter to obtain good flowers. In Scotland and in some of the hilly districts of northern England first-class blooms can be grown with a minimum of trouble, and plants in districts that lie well above sea level are rarely troubled with disease. They are not widely grown in the south, but it has been proved that certain kinds can be grown successfully there, and there is no reason why the strongest of the bedding varieties should be excluded from southern gardens.

Pansies and violas should be grown in beds or borders where they receive the full benefit of the morning sun; but, if possible, they should be protected from the scorching effect of summer heat. Trees that are planted some distance away, walls or fences, will often provide the necessary shade; but where the situation is open it may be advisable to use artificial means of shading them in the height of summer. To plant them in a low-lying part of the garden, even if this be shady, is not a good plan, as in a wet season there are many casualties among plants in such situations.

A study of the structure of the plant will reveal two sets of roots, one that penetrates to a depth of five or six inches, and the other reaching out among the surface soil. The soil should be cultivated to a depth of a foot or more to enable the longer roots to have a cool run, and when the plot is being dug over it is a good plan to work in a liberal quantity of well rotted animal manure and bone-meal as sustenance for the plants throughout the season and a source of food supply when the surface roots cannot perform their functions during a period of drought. A mulch applied during hot weather is beneficial in tiding the plants over a dry spell, but unless they have a good foundation in the lower levels they cannot keep up a continuous display of flowers of the highest quality. If beds or borders have not yet been prepared this should be done without delay so that the soil has time to settle before planting time.

It is unwise to plant out too soon. March planting is quite early enough in the south; northern growers would be well advised to wait until April. Early planting sometimes results in loss of plants or withered growths as a consequence of late frosts or cold east winds. This is more noticeable in exposed districts.



WILLIAM BARR A FINE WHITE VIOLA WITH WELL SHAPED FLOWERS.

When planting out choose a day when the soil is friable and plant firmly. If the plants have been raised at home or obtained locally keep each rooted cutting in its surrounding ball of soil, as the young roots are very tender and must not be damaged or become dry. A well grown plant in autumn will often measure 6ins. in diameter, so that it is well to give as much space between the plants as is possible. If they can be planted a foot apart so much the better, as this also makes it easier for hoeing and mulching during the summer.

Bedding violas are specially recommended for those who desire a long and continuous display of bloom regardless of the size of the individual flowers. They have a tufted habit, generally a sturdy growth, and most of them will come through an ordinary winter unprotected. They are easily propagated from cuttings or by division of the old plants in the spring. Rooted cuttings after becoming established can be left undisturbed for two seasons, when they will give an early display the second spring and afterwards may be trimmed to preserve a neat appearance. Selections may be made in selfs, fancies, edged and bordered varieties or bronze shades. The latter should be protected from the fierce rays of the sun in the middle of summer, as they are apt to become scorched. A dozen reliable varieties might include Swan (the best white bedder), Lady Knox (cream), Royal Sovereign (pale yellow), Tangerine Harrison (deep orange), Moseley Perfection (deep yellow), Maggie Mott (pale mauve), John Quarton (light mauve), W. H. Woodgate (light blue), Improved Archie Grant, or Edina as it is called in Scotland (dark blue), Royal Purple, Pride of Darras (white with a broad band of purple) and Jubilee (dark velvety purple).

The exhibitor must look for larger-flowered varieties, for, with the exception of Moseley Perfection, the above-named are either small or medium flowered. During the past few years

AN EXAMPLE OF THE EFFECTIVENESS OF WELL FLOWERED VIOLAS IN A BED BY THEMSELVES.

Digitized by Google

I have grown most of the leading kinds, both old favourites and newer introductions, and although personal taste plays an important part in the matter of selection, the following twelve should please the most fastidious grower: William Barr (white), John Adamson (orange self), Kathleen Condry (deep purple), Mrs. Andrew Stevenson (deep yellow with a heavy band of deep heliotrope on the side and bottom petals and a suffusion of the same colour on the top petals), Mrs. William Boyes (lemon yellow with a picotee edge of lavender), Jean Drummond (lemon yellow self), John Wood (one of the best striped varieties), Lily Stark (deep violet with lavender top petals), James Dewar (white with picotee edge of blue), Mollie Gibb (creamy white with picotee edge of heliotrope) Olive Harrison (primrose edged with sky blue) and Mrs. R. Beveridge (a distinct shade of lavender-pink).

Some of the exhibition violas, such as Sir Edward Grey and Master Stevenson, while being capable of producing fine individual flowers, are of too straggly growth to be useful for general garden decoration; but many of the newer, large-flowered type, such as John Adamson and Olive Harrison, have a splendid habit and can be used for bedding or massing if desired.

There is a type of pansy, known as the bedding pansy, of which Messrs. Dobbie and Co.'s richly coloured Bellfield is a notable example, which promises to be used largely for massing and bold colour effect. In this class there are now many lovely shades of bronze.

As a rule, pansies are more inclined to grow "leggy" and sprawl, but if they are used for garden decoration I have found that they are very effective if planted fairly close together and allowed to ramble at will, when the growths and flowers become intermixed in a sort of abandon that gives quite a brilliant and varied effect in the mass. The exhibitor who grows pansies, however, must be more orthodox in his methods. It may even be necessary to shade them, to restrict the flowering and to thin out side growths.

A dozen up-to-date fancy pansies might include Mrs. Andrew Frater (plum purple, sulphur yellow, old rose and magenta), Annie Beveridge (deep violet, terra cotta and lemon), Robert Beveridge (deep purple, white and magenta), Mrs. A. B. Cochrane (purple and cream), Jean Lister McKellar (dark purple and creamy white), Dr. McKinnon (plum, lemon and rosy purple), Mary Drummond (brown, deep yellow and crimson), Dr. Ogilvie (dark purple, white and violet), Nellie Cochrane (light purple, claret, white and crimson), John Greig (dark purple, crimson, canary yellow, light purple, violet and white), Mrs. A. Harrison (dark violet and cream) and Alexander Lister (plum, rose and white), an old variety, but one that is still very popular and one that gains the prize for the best bloom in the show more than any other. The new variety, A. R. Stevenson (claret, pale chrome, yellow and wine colour), is said to be one of the finest pansies of recent introduction, and it will probably prove to be the sensational novelty of the forthcoming season It bears the name of one of our greatest raisers.

NORMAN LAMBERT.

LILIUMS: PLANTING AND SOIL CONDITIONS

A FINE GROUP OF LILIUM CANDIDUM.

WITH the exception of a few Indian species, most of our cultivated lilies are hardy, especially with a little protection in the case of some American ones; losses during the winter generally resulting from damp, which is probably much more fatal than cold.

The cultivator of a choice collection of lilies under our climatic conditions is confronted with a difficult problem: for, during the summer months, a considerable amount of moisture at the root is essential for success, whereas in the winter this dampness will prove fatal. The grower of choice lilies is thus faced with the problem of providing conditions that will be more or less suitable for both summer and winter. Here we may take it for granted that suitable winter conditions are the more important of the two: and the most essential point is sharp and perfect drainage, which may be a possible disadvantage during dry weather in the growing season. This is not serious, as long spells of dry weather are not at all frequent, and the difficulty can be overcome by means of watering. I shall try to show that good winter conditions may be obtained by free drainage, without causing the bulbs to suffer unduly from dryness at the root during the summer.

In nature most species of liliums grow in association with other plants; it may be that shrubs, grasses or herbs, and the roots of neighbouring plants keep the soil in good mechanical condition. Here, I feel sure, is the clue to our failure to grow many lilies—and, indeed, many other plants—successfully, for they lack the association of other plants which help to keep the soil well drained and in good mechanical condition. Considering this, it is not surprising that we frequently fail with a choice lilium, a few bulbs of which are often placed in a bed or portion of a bed utterly devoid of roots, causing the soil to become water-logged during winter, with the result that the bulbs fail to make roots and ultimately decay. On the other hand, there are quite a number of good garden lilies that will succeed quite well in any good properly drained garden soil. For example, such strong-growing garden lilies as L. candidum, L. croceum, L. Martagon and its varieties, L. tigrinum, L. testaceum, L. Henryi, L. umbellatum, L. chalcedonicum

Digitized by Google

and L. elegans. All the foregoing are loam lovers, and many failures with them are due to the fact that peat is used in the compost. Lilium candidum should be planted during August, while all the others should be planted as soon as the bulbs can be obtained; or, if stocks exist, replanting should be done as soon as the stems have partly dried up, some time during October being the most suitable, while the ground is still warm. If there is any suspicion that the planting sites are not well drained, the soil should be removed to a depth of at least 2ft., or even 2½ft., this to allow room for plenty of drainage, which should consist of 6ins. of clinkers or any small rubble. There is no reason why some soil should not be mixed with the drainage. Under these conditions healthy bulbs should come safely through the winter.

With sharp drainage one is faced with the necessity of watering during spells of dry weather, and if it can be arranged some system of sub-irrigation is undoubtedly best. In a small way this could quite well be done by inserting a length of small drain pipe at the side, or even in the centre, of a group of plants. Although this, under certain conditions may be desirable and necessary, especially where many choice species are grown, I do not in a general way consider it to be essential. Where the collection of choice species is large, it might be advisable to construct a special bed with underground perforated pipes for watering purposes; but, generally speaking, we must regard this as being beyond the resources of the average cultivator, and is only necessary in exceptional circumstances. I would, rather, advise the use of ample drainage in the form of rubble mixed with a little soil, 1ft. or even 18ins. below choice lilies, which will ensure sharp drainage during the winter months, and, what is of prime importance, will conserve moisture at the roots during dry weather; and by this simple method we achieve the two-fold object. During dry weather the surface moisture may be conserved by mulching with well decayed flaky leaf-soil; a mulch of this kind is especially valuable in the case of stem-rooting lilies. When drainage of this description is provided, it is surprising the mass of roots which will develop in it; and in this connection we have a parallel in the moraine or scree bed in the rock garden, where many small, choice, deep-rooting alpine plants can be successfully grown, whereas they are more or less failures when grown in ordinary soil.

Returning to the planting of our lilies, I would advise, when preparing the sites, that a hole from 2ft. to 2½ft. deep be made, varying the depth according to the strength of the species to be planted; 12ins. to 15ins. of the prepared drainage should be placed in the bottom of the holes, afterwards filling them in with prepared compost, which, of course, will vary according to the species; but a good medium loam, with the addition of well decayed leaf-soil and plenty of good gritty sand, should answer for most of the species in cultivation. This prepared compost should be trodden fairly firmly—I find it is a common mistake to leave it too loose, which results in its getting water-logged by moisture draining in from the firmer surrounding ground. Here I am assuming that the planting sites are being made in beds of dwarf shrubs, as in a general way they afford us the best conditions for success, since their roots help to keep the soil in good mechanical condition, as well as affording the young shoots shelter from cold cutting winds during the spring, and providing a certain amount of shade for the roots during the summer—all three important essentials for success.

LILIUM TESTACEUM IS MOST EFFECTIVE AGAINST A BACKGROUND OF TREES.

ONE OF THE MOST GRACEFUL OF LILIES, L. MARTAGON ALBUM.

The sites should be prepared immediately before, so that the compost is always in good working condition; the holes being filled up to within 9ins., 6ins. or 4ins. of the top, according to the particular species. For example, stem-rooting lilies should be planted deeper than species that do not produce roots from the stem; while large bulbs, naturally, should be planted deeper than small ones—although there are exceptions to this rule. For instance, in the case of L. candidum and L. giganteum the top of the bulbs should be little more

Digitized by Google

than covered; on the other hand, bulbs of L. auratum and L. Henryi may be planted 1ft. in depth.

Having put in the prepared compost to the required depth, taking care to tread it firmly, a layer of sharp gritty sand should be added, pressing the bulbs into this, and a covering of sand given; the holes should then be filled in slightly higher than the surrounding soil, as the fresh compost is sure to sink a little, and pressed fairly firmly, afterwards marking the sites with a short bamboo cane.

When preparing the compost I consider it is an advantage if a quantity of small stones are mixed with it, as they conserve moisture and assist drainage. Some cultivators when planting choice lilies place an inverted flower-pot underneath the bulbs, while others lay them on their sides to prevent wet lodging in the scales. When proper drainage is provided, I doubt if such methods are necessary, but that is a matter that rests with the individual, and when dealing with this fickle and beautiful race of plants no possible means of securing successful results should be neglected.

Certain Californian species, such as L. pardalinum, L. Parryi and L. Humboldtii, are often spoken of as swamp lilies; the beginner should not be misled by this, for no lilium is likely to be happy or live long in swampy, stagnant conditions. In their native habitats the species in question may grow in moist situations, such as streamsides, etc., but it is certain that the bulbs are always high and dry, even if their roots do reach down to the moisture underneath, and that this underground water is nearly always moving, and not stagnant. In any case, we must remember that there is a vast difference between natural conditions and what we are able to give the plants under cultivation, for, as I have already hinted, plant association in nature plays an important part in plant growth. Again, it does not always follow that if we try to reproduce natural conditions in the garden that success will follow in the cultivation of plants. If we take L. pardalinum as an example: one is generally advised to give it plenty of peat in the compost, whereas it really succeeds best and increases freely when grown in ordinary well drained loam, with the addition of some well decayed leaf-soil. In nature, liliums cover such a wide geographical range and grow under such varying conditions that it is difficult to lay down any definite rule as to local conditions. Although the latter play an important part in the successful cultivation of any particular species, good drainage (and shade at the root) is of chief importance. Also, at the same time, under our climatic conditions, they can do with full exposure to the sun: with the exception of L. giganteum and L. cordifolium, which are woodland lilies and—in the South, at least—require a certain amount of shade, although in Scotland they do splendidly out in the open with full exposure to the sun.

J. COUTTS.

ANEMONES FOR BEDS AND BORDERS

IN ANY GARDEN, ANEMONES, WITH THEIR VARIETY AND WEALTH OF COLOUR, ALWAYS FORM ATTRACTIVE SUBJECTS.

THE name anemone recalls at once to the minds of many the vision of a woodland or copse in April with the sun shining through the leafless trees on to a snowy carpet of dainty woodland anemones gently waving in the breeze. These anemones are fragile, but among the whole genus (often called the windflower) there are cultivated species suitable for the wild garden, a most valuable group for the rock garden, and a number of sturdy members which are very effective in beds alone or in the mixed border. The size and form of anemones vary from the small tufts of A. Pulsatilla to the tall heads of A. japonica, which are borne on stems nearly 4ft. in height. The colours in anemones are countless.

Although border anemones are long established favourites, within the last thirty years some of the species have been improved to such a great extent that a much larger number are being grown. There are two distinct branches in the border types, the spring-flowering kinds and those which bloom in the autumn. Among the early-flowering type the most important species are the tuberous-rooted A. coronaria, A. fulgens, A. alpina, A. sulphurea and lastly, A. sylvestris. The chief autumn-flowering anemone is A. japonica and its many varieties, which are all herbaceous plants. Of all these A. coronaria is the largest section and it is upon this group that the efforts of the specialist have been concentrated. From the wild species, the poppy anemone of Asia Minor, various strains have been produced by selection, for example there are the "Caen" type of French origin, the double "chrysanthemum flowered" race, the double Nice anemone, and the most recent of all, the St. Brigid strain. The latter are semi-double, and all are in a great variety of beautiful colours. There are single as well as double kinds of the "Caen" anemone.

A TYPICAL ST. BRIGID ANEMONE.

The poppy anemone and the various strains thereof thrive in warm deep soil, but they dislike cold and damp during the winter. Some growers hold that the cold wetness of winter is very liable to injure the plants and that the tubers should be lifted after flowering and stored until the planting time. On the other hand the disturbance of the roots is more likely to cause poor results than the effects of damp, and the best method is to plant the tubers in really well drained soil and leave them untouched, unless, of course, the soil is particularly heavy.

The St. Brigid anemone is worthy of good treatment and if the cultural details of this are mastered, any of the other types of poppy anemone will flourish exceedingly when grown in a similar way. Their great variety of colours and their robust, sturdy growth are two factors which make people anxious to grow them. The latest forms of St. Brigid anemones are vastly improved and vary from deepest crimson to purple, brilliant scarlet, delicate blue, pink, mauve and violet to almost white. Some are distinctly

Digitized by Google

zoned with white, red or rose. All the shades blend harmoniously together and of all the anemones the St. Brigid look perhaps more effective when planted in beds by themselves rather than intermingled with other flowers in the herbaceous border. The flowers are borne on strong, erect stems and the broad petals form a shallow cup.

The secret of success with St. Brigid anemones is to give them firm, well drained soil and plenty of moisture during the growing season. Firm planting is essential and the roots should never be disturbed with any tool; when weeding is necessary it must be done by hand. These tuberous-rooted anemones are propagated by means of seed or division of the tubers. The tubers are planted in October or November and again in spring and later. If some are planted now there will be a fine display of flowers from early summer onwards. By planting at different intervals a succession of bloom is obtained. The most suitable

ONE OF THE BEST AUTUMN FLOWERING ANEMONES, A. JAPONICA CRISPA.

soil is friable, rather heavy loam. If the soil is very heavy clay it should be artificially drained and a liberal dressing of sand given. Well decayed cow manure and chopped-up old turf greatly improve the beds, and should be well mixed with soil to a depth of 15ins. to 18ins. when the beds are dug. Leave the beds for a short while to settle, and then just before planting break up the surface and rake level. The tubers are irregular in shape and, when planting, the growing knob should be placed upwards and the tuber laid flat at the bottom of the hole. If in doubt as to which is the growing point, plant the tubers sideways and they will automatically right themselves. There are often the remains of root fibres on the underside which are a help in recognising the correct sides. The tubers can be divided, and each piece will grow provided it has a growing point. This is not often done except for breeding purposes. Before planting make the bed thoroughly firm, and, by means of a thin stick, drill holes exactly 3ins. deep and 4ins. apart; drop into each a root, then fill up with soil. When the whole bed is finished it should be made firm by pressing with the back of a rake or rolling with a light wooden roller.

After autumn planting some growers cover the beds with leaf-soil as a means of protection, but this is not necessary in most districts. If the flowers show signs of developing before sharp frosts have ceased, a light covering can be given. St. Brigid anemones planted during October and November bloom from the following April, those planted in the spring flower from early summer onwards according to the season. Flowers are produced for several years if the soil is particularly suitable, and, as it has already been said, the tubers should not be disturbed until they appear to be worn out or the ground needs replenishing.

During the growing season these tuberous anemones should have a mulch of well rotted short manure to keep the roots cool and moist. If this is not sufficient and the roots appear to be dry, copious supplies of water should be given. Mulching, watering and hand weeding are necessary during the summer months, and until it is time to renew the beds a brilliant array of flowers will be obtained with a minimum amount of labour.

When the beds begin to show that they need replenishing, preparation should be made for increasing the stock. This can best be carried out by purchasing some more tubers, for unless seedlings are carefully raised vigorous tubers are not formed, and thus it is more satisfactory to buy from some reliable grower.

Other species can be raised from seed sown as soon as it is ripe in July, and seed from only the best coloured plants should be used. A bed in a warm situation should be well prepared several weeks before sowing in the same way as advised for the permanent beds, but a larger proportion of well decayed cow manure thoroughly incorporated with the soil produces a more suitable compost. The seed is encased in a woolly covering which causes it to adhere together, making thin and even distribution some what difficult. To overcome this, mix the seed with slightly damp silver sand and rub between the fingers, by which means the seed is separated and can be scattered easily. Rake and make the bed firm before sowing. The seed should be sown in drills ½in. deep and 10ins. apart or it can be scattered broadcast over the bed. When the sowing is completed cover lightly with some fine soil and give a little water if the ground is dry.

Until germination has taken place, some means of shading the beds is necessary. Tiffany, sheets of newspaper or evergreen shoots can be used. When the seedlings are up, which will be in about one month's time, remove the covering and give a watering, and leave them in the seed bed until the following year. They will bloom in April and directly the foliage has died down and before second growth has started they should be lifted, dried and stored until they are planted in their permanent quarters in October.

A. fulgens, the vivid scarlet windflower can withstand frost, but not stagnant moisture. It needs a rich, well manured loam in a position in partial shade. Its beautiful scarlet flowers look equally attractive in a mixed border or in a little nook on the rockery, while in a bed by itself A. fulgens makes a wonderful effect. The most satisfactory way of propagation is by division of the roots in early autumn, but it can also be planted in February and March.

The alpine windflower, A. alpina grows to a height of nearly 2ft. Its creamy white flowers are purplish outside and division is the surest way of propagating it. Seed is the best method of increasing the variety Sulphurea of A. alpina and it needs a warm well drained soil and plenty of moisture during the summer. Both of the last two anemones bloom during May.

The pure white snowdrop anemone, A. sylvestris, in any border is a delight to the eye. Its delicate drooping flowers are borne on stems 1½ft. in length in May and June. This is suitable also for shady places and it should be increased by division.

A. japonica is known to all; its handsome white or rose-coloured flowers are seen during the autumn decking the borders, the shrubbery or the woodland of many gardens. It is an herbaceous perennial and once it is established, if left untouched will go on flowering for some years, especially if the soil has been well dug and given a liberal dressing of manure before planting. There are several excellent varieties, such as Queen Charlotte, rose coloured and darker outside the petals; Lady Ardilaun, a pure white single; Alice, silvery pink and semi-double; and alba, a pure white form of A. japonica. They vary in height from 2½ft. to 3ft., and continue blooming until they are cut down by frost in late autumn.

THE CULTIVATION OF THE GLADIOLUS

BY MAJOR G. CHURCHER.

THE SWORD LILIES INTRODUCED FROM SOUTH AFRICA ARE AMONG THE FINEST, HARDIEST AND MOST FREE FLOWERING SUBJECTS IN OUR GARDENS, WHERE THEY SHOULD FIND A CORNER HOWEVER SMALL.

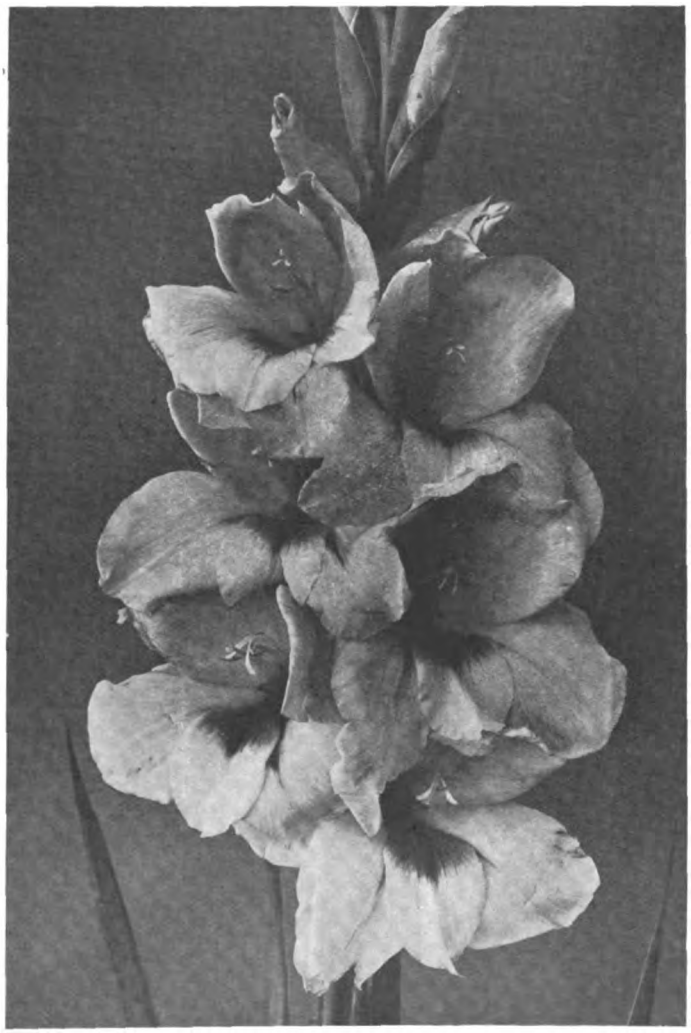
THE gladiolus has been well described as the most decorative and most easily grown of all summer-flowering bulbs. Certainly there are few flowers that can vie with it for decorative use and lasting qualities, when cut for the house. Yet, like many other plants, it repays you for a little extra care and attention.

Those who have had some experience with the flower will have taken care to see that the proposed beds have been well and deeply dug and any necessary manure applied during the winter; and have, no doubt, been looking at the bulbs recently with a view to getting them back to Mother Earth.

The bulbs themselves have, by the indication of rootlets shown that they too think it is getting near planting time. The mild weather has, no doubt, been the cause of this early tendency to grow. It might therefore be as well to remind those who have not had much experience with the gladiolus, of the necessity to unpack the bulbs as soon as received and open the bags so that the bulbs may have plenty of air. There is one exception to this rule, and that is in the case of bulbs coming from Canada and the U.S.A. It is just as well to let the package remain in a cool place for twenty-four hours before unpacking, and do not allow the bulbs to be subject to a rapid rise of temperature.

Let us now assume that the beds have been properly prepared and the soil is in a workable condition, the bulbs may be planted, according to size, from 3ins. to 8ins. apart, having regard to the space to be filled. Bulbs of different varieties vary greatly in size, without in any way affecting their blooming qualities. Large flat bulbs are generally old and of little value for the production of large flowers. Judge by the depth of the bulb, rather than the width. If planting in rows, after many experiments in various distances, it will be found that 2oins. between the rows is the least width to give good results. This width enables the soil between to be kept well cultivated. Should space be valuable, plant in double rows in the same way as you would plant broad or runner beans, leaving the full width of at least 2oins. between the rows. The depth of planting must be governed by the size of the bulb and the soil conditions. A sandy loam is more suitable for deep planting than a stiff soil. Deep planting helps to overcome the need for staking.

Successive plantings used to be advocated for prolonging the blooming season, but there is such a difference in the time required by the different varieties to attain their full growth that a succession of bloom can be obtained by selection. This will be quite understood when it is known that the time varies from 60 to 120 days. If, however, it is desired to have one particular flower over a long period, successive plantings from ten to fourteen days should be made.



G. BLERIOT CARRYING A LARGE SPIKE OF BEAUTIFUL ROSE TINTED FLOWERS.

The gladiolus likes water, provided good drainage can be assured, and good cultivation will be of more benefit than artificial watering. Keep all weeds down and the top soil loose and in a mulch condition. If watering becomes necessary always follow with the hoe before the surface has had time to cake.

Artificial manures are best given in liquid form and when the ground is moist. Lime improves the colour of the foliage and the bloom.

Some people think the gladiolus is too stiff for use in beds, but I would suggest that very effective beds may be had by planting a groundwork of antirrhinum with the gladiolus coming up between. Most of us have grown beds of yellow or blood red wallflowers with red or yellow tulips showing above. The same idea of colour combinations may be worked out with the gladiolus and antirrhinum. Heliotrope can also be used as a groundwork with one of the yellow or white varieties of primulinus. In borders good broad stretches of colour should be made against a background of delphiniums and Michaelmas daisies.

The number of varieties has greatly increased during recent years and some confusion in the names has been the result. Some growers, however, are trying to clear away this bugbear. Two or three years ago I bought Highland Laddie as a new variety and this year I find Mr. Kunderd has a new introduction of that name with the following note:

"By mistake the name of Highland Laddie became attached to my old variety, 'Red Copper.' I have purchased the name from my friend Mr. McKibbin and given it to this very beautiful new pink."

At one of the meetings of the R.H.S. last year I was attracted by a flower on one of the stands, but the name Bleriot did not appear to me correct. I asked the attendant and I was assured that it was correctly named. However, I was not convinced that it was like the flower I grew under that name and on looking up my notes I find that my Bleriot was raised by Vilmorin and received an award of merit in 1914. It was not a particularly good doer, but it flowered in 1916, 1917 and 1918; the colour description was carmine lake, overlaid with plum violet, small blotch of creamy white. The flower illustrated is thus described in Messrs. Bath's catalogue: Apricot rose, with orange throat, lovely colour, large flower, good spike.

Many more instances of duplicate names might be given, but the above illustrations will be sufficient to remind readers that in taking notes at shows care should be made to add to the names the colour descriptions of the flowers, as comparisons can then be made.

PLANTING THE WATER AND BOG GARDEN

(*Continued from page* 144.)

WITH THE EMBELLISHMENT OF THE SIDES OF LAKES AND PONDS IN THE GARDEN BY THE JUDICIOUS SELECTION OF SUITABLE PLANTS, A NEW CHARM IS ADDED TO THE GENERAL LANDSCAPE EFFECT WITH A MINIMUM OF TROUBLE.

OF all the herbaceous plants that beautify the water garden none offers quite the same attractions as the astilbes and spiræas.

The astilbes (goatsbeard) alone are becoming a formidable list of plants. There are several distinct types, and most of the remainder are hybrids between these. They love the water's edge, where they can get their roots right down into the wet mud in summer. Nor do they object to this saturation in winter. The finest species are A. Davidii, a really beautiful plant if it can be isolated from any other colour, but it is of that shade of bluish purple (the minute anthers are bright blue) that maddens the colour sensitive when placed in juxtaposition with any other colour. A. grandis is perhaps its safest companion, being white. A. rivularis and an improved form known as A. r. major are also white and bold, graceful plants with nothing quite equal to them for the extreme water's edge. The old well known A. chinensis with its slender pale pink plumes completes the list of the necessary types. All the remainder, of which their name is legion, are hybrids between the above. Cream Pearl, Princess Mary, Salmon Queen, Vesta, Rubella, Siegfried and others, all varying shades, white to the deepest salmon pink and some nearly approaching purple. All are worth growing.

The spiræas have occupied the hybridist less than the astilbes, and the available list is therefore more limited. No water garden should be without the glorious crimson S. palmata or its pink form, S. palmata elegans. There is a white form also for those who desire it. Another indispensable is S. venusta and a bolder habited deeper pink form called S. venusta magnifica. The distinction is so marked between these two that I have sometimes wondered whether the latter has any right to pose as a venusta at all. It suggests S. gigantea in its habit of growth. S. gigantea (Kamtschatica) is a noble species for the large water garden, but is too rampant for small areas. It will grow 8ft. high and in a very short time as much through. S. Aruncus is a very fine and graceful plant. S. filipendula plena (double dropwort) and the double meadow-sweet, S. Ulmaria fl. pl. completes the list.

About equal in order of merit with astilbes and spiræas for the purpose we are discussing are the moisture-loving irises, and the queen of the race for this purpose is undoubtedly Iris Kæmpferi, better known as the Japanese iris. Having made that statement I feel constrained to qualify it. All the varieties of I. Kæmpferi succeed well in rich, damp soil, but permanent moisture is not really essential to their well-being. During the growing season they insist upon plenty of it. During the dormant months they are better without too much wet at their roots. They like a situation where they can get their toes down into the cool moisture in the hot days of early summer. They are happiest if the water recedes from them in winter. There are nominally about seventy or eighty varieties of them, actually there are about twenty-five or thirty distinct sorts that are worth growing separately. The colours range from the purest white to the deepest violet-purple.

After Iris Kæmpferi come a whole range of species, all of which like more or less moisture and some revel in wet conditions. The largest class of these is the Siberian subsection of the beardless irises. Of the true Sibiricas, Purple Emperor, Perry's Blue, Orientalis Snow Queen and a variety named last summer (on account of its colour) by Mr. E. A. Bowles Kingfisher Blue, are the best. Closely allied to these is the somewhat variable, so far as colour is concerned, Iris Delavayi. The stock at present in commerce is the produce of seeds sent home by Wilson, in which there have always been variations in colour, and to some extent in form. The best of them is a wonderful and richly coloured violet, known as I. Wilsoni, one of the species that only gives of its best under moist conditions in the soil. I. Bulleyana, lilac and purple, and I. chrysographes, deep red-violet with golden veins, are others of value in this group.

PRIMULA SIKKIMENSIS, A SOFT LEMON YELLOW.

The sub-section Iris Spuria does not insist on moisture, but succeeds in damp ground admirably. The same remarks apply to ochroleuca (orientalis), a giant ivory white; aurea, golden yellow; Monnieri, primrose yellow, all these three growing 4ft. to 5ft. high in rich damp soil, and the hybrids Mon-spur and Mon-aurea are equally satisfactory.

I. lævigata, a Japanese species that was for many years credited with the parentage of the Kæmpferi race, is a beautiful violet-flowered plant, and revels in bog land, as does a beautiful form of it, alba purpurea. By the way, there are two forms of this plant in existence, that recognised by the Royal Horticultural Society some years ago as "Colchesterense" being quite distinct and infinitely the better plant.

Iris fulva, a reddish copper-coloured plant, I have known make its way into a wet ditch and flower beautifully.

There are other irises for the waterside, but those enumerated should suffice as a nucleus, and the only other I will mention is pseudacorus, the wild flag of our English waterways, which will grow admirably in the water, but if allowed to do so will take possession of all the area in its neighbourhood. There is a variegated form of it that is very effective by the waterside and should always be included in any planting. Many people do not care for variegated plants in the ordinary way, but this is one of the exceptions that can be admitted with no fear of its offending in any form. This also applies to another variegated form of a native species, I. fœtidissima aurea.

Digitized by Google

So far I have only mentioned summer-flowering plants, the iris beginning in late May or early June and flowering until the middle of July. Astilbes and spiræas begin in late June and flower on through July and August. Lilies, late June, July and August.

The primulas, however, will fill in the space during the earlier weeks, and no genus offers such a wealth of brilliant colour. First there is Primula rosea that will remain submerged during most of the winter and then thrust up its dainty pink flowers as soon as the water recedes and the sun shows itself in the spring. This is followed closely by P. denticulata in mauve and lilac shades, some modern seedlings being deep rich purple. P. kashmiriana is a form of this species with flower-stems and the ribs of the foliage much powdered with fine silvery dust or meal, and has been known to grow 2ft. high and as much across. P. pulverulenta is perhaps the most telling of the whole species, with its giant whorls of deep crimson flowers on stems 3ft. high, in May and June. The leaves and calyces in this also are beautifully coated with farina. P. Helodoxa, introduced from China by Forrest some years ago, is a wonderful plant with bright golden yellow flowers. It made its *début* with acclamation, and was hailed with delight as a promising parent and a permanent addition to the bog garden. So far it has proved neither permanent nor parentally inclined. I have known of many attempts to cross it with other species, but none that has been successful has come to my notice yet, and yet if one could only get it to cross, what a wealth of beautiful forms might emanate from the results!

Primula japonica is a rampant grower where it does well, and has produced, in addition to its own crimson, many variations of colour, some of which are better than the type, many are inferior and a few are of a negligible attraction. P. Beesiana, purple, and P. Bulleyana, orange, are two other Chinese species that must be included. P. sikkimensis, with its tall, graceful stem and soft yellow flowers, is always welcomed.

And now what shall I say of the numerous hybrids, pulverulenta ×, Cockburniana ×, Bulleyana ×, Beesiana × and all the other crosses. They are exceedingly beautiful, many of them, but it is folly to mention by name plants that may only be a memory when these lines are in print. Some few are, shall I say, partially perennial, and these may be propagated true. Many are biennial, and these can only be raised by seed. The result is that many have been named and in about the second or third generation have ceased to exist, as they produce every imaginable variation.

The primulas bring us very near the water's edge, so while here we may as well notice other plants that like a similar position. Such are the calthas (marsh marigolds), of which the two best are the old Caltha palustris fl. pl. and the larger-leaved, bolder-habited C. polypetala, Both grow well in shallow water or along the wet banks, and their golden glow is very valuable in the early spring.

The marsh musk, Mimulus luteus, and hybrids between this and M. cupreus are invaluable, as they flower throughout the summer, and common as M. luteus is, I know of no finer combination than its pure yellow mingled with the light blue of the water forget-me-not (Myosotis semperflorens) at the water's edge. Polygonum bistorta, a pretty pink moisture loving knotweed, is another desirable plant. Indeed, all the polygonums are happiest in moisture. Astrantia carniolica (masterwort) also likes the water's edge. Epimediums, for the beauty of their foliage as much as for their dainty flowers, should be planted freely as a carpet to other plants. The lythrums (purple loosestrife) give a glow of rich purple or deep rose late in the year that mingles charmingly with the earlier changing autumn foliage in the water garden. Lysimachia (yellow loosestrife) in several species are useful, but should not be planted too freely, as they are certainly somewhat aggressive, a remark that applies to the purple loosestrife also. Pimpernella magna rosea (the Burnet saxifrage) with its umbels of rosy flowers is a good late summer plant.

All the ragworts, or senecios, have bold, handsome foliage as well as large showy flowers. S. Clivorum is worth planting for its foliage alone, but when covered with great golden flowers is telling indeed. S. japonicus (syn. Erythrochaete palmatifida) is equally beautiful and grows taller. S. tanguticus is better for foliage than for flowers.

GEO. DILLISTONE.

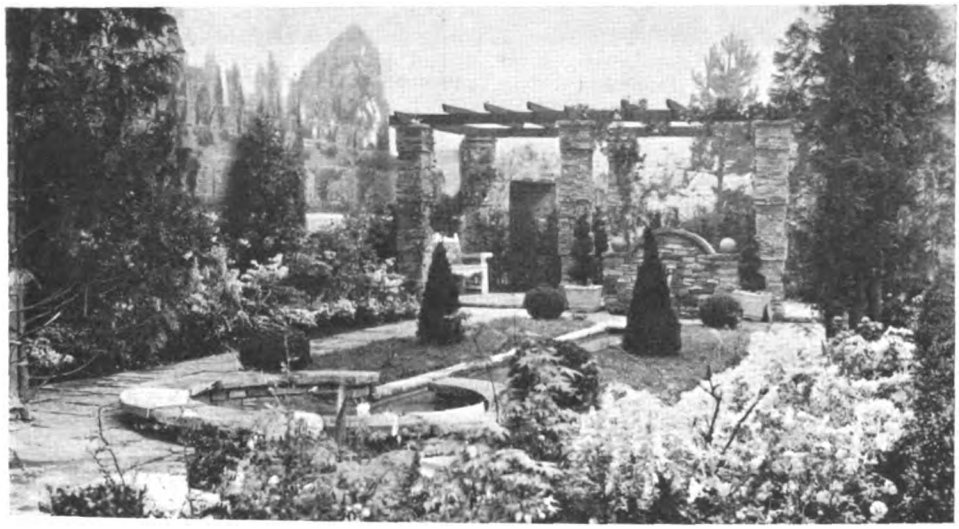
THE GARDENS AT OLYMPIA

IN this year, at the Ideal Home Exhibition, if not before, the nurserymen who lay out gardens have certainly excelled even their efforts at Chelsea. Naturally, at Olympia they know that they are not hampered by the weather, and so they can allow themselves a certain freedom of action; on the other hand, they have here nothing but a concrete floor to work on. The standard at Olympia has been improving every year, and this year, on the whole, it has reached a height which it would be hard to better. The only criticism that can be made is that in one or two cases the plants have been packed too tightly together in the beds. A realistic garden is being aimed at, so why crowd the plants to such an extent that they could never exist in reality in such mass formation. It is true that the appalling season has reduced plants in flower to a minimum, but overcrowding is worse than too sparse planting, for in the former all plants lose their individuality, which should only be the case in annuals and a few exceptions in shrubs and herbaceous plants.

Of the more ambitious by far the most effective lay-out is the garden designed and made by Messrs. Carter. This represents a formal Riviera hillside garden and, is probably the best garden that has ever been staged at an exhibition or show. In the making of this garden Messrs. Carter have gone to an immense amount of trouble and expense; as an example, over 150 loads of earth have been carted into Olympia for this one garden; but a little examination will show that, given a slope and leaving out the garden house, such a design would not be expensive to execute, while its effectiveness is undoubted. At the back is a terrace, on which are flowering azaleas and flowering cherries like Prunus triloba, while on the sloping sides are planted conifers of various kinds. Below the top terrace is a second one, which is made on a curve. In the middle of the curve is a circular pool, with a many-sprayed fountain, which is surrounded by hybrid Primula malacoides. The overflow from the fountain splashes into a formally designed tank at the base, while in the immediate foreground are groups of daffodils flowering in turf. The beauty of this garden is the way in which the actual terracing around the central theme of the fountain gives way to the slope of the bank in the most natural manner possible. On the slope on either side of the central terrace are planted further groups of azaleas. We have nothing but praise for the general lay-out and planting of this garden, and it reflects great credit on Mr. Bard and his staff for producing such a fine exhibit. Messrs. Carter have also designed Messrs. Lyons' Japanese tea-garden, but this is more a conventional design, although quite effective.



THE STRICTLY FORMAL GARDEN OF MR. G. WHITELEGG.

A RIVIERA HILLSIDE GARDEN AS DESIGNED BY MESSRS. CARTERS'

Another effective garden is that of Messrs. Cheal. Here the design is quite conventional and formal, but the result is excellent. In the centre is a rectangular plot with a stone path running up the middle and four beds of different-coloured hyacinths in bloom. Surrounding this plot is a narrow border devoted to low-growing shrubs such as skimmias, Andromeda calcyculata nana, and azaleas, among them A. Ribiera with semi-double tubular flowers of a blush white. This belongs to a group of azaleas that might be more often grown in gardens. This border in turn is backed by a row of yews, while at the back is a small terrace on which are also planted shrubs like lilacs and Viburnum Carlesii. This is a type of garden that is particularly well suited for small areas. The central beds can be filled several times during the season, while the shrubs can be so selected as to give the maximum amount of colour throughout the year.

Messrs Allwoods' are showing a novel design for a carnation and pink garden where the maximum amount of effect can be given with the minimum amount of labour. This is composed of twin lines of double banks, each surmounted with a low wall. These banks have a very moderate slope and have beds cut in them for carnations and pinks. The result of this gentle slope is that the whole contents of the bed can be viewed from the right angle of vision. We cannot remember ever having seen such a design before.

Of rock gardens we consider that Messrs. Maxwell and Beale's is the most effective but is closely followed by that laid out by the Orpington Nursery Company. The latter has an advantage, for it is laid out at the side of the hall, and thus has a background; while the former is in the middle and has to be a complete entity. Messrs. Maxwell and Beale's exhibit consists of a small stone-flagged court with tulips in beds, a terrace of untrimmed stones planted on the top with polyanthus and a very naturally planted rock garden at the back. It is not overcrowded, and the groups of erica, primulas and so on are very effective. The Orpington Nurseries exhibit an alpine meadow with a little stream and rocky pools. The central theme of this exhibit is heather, plants of which are scattered promiscuously in the grassy levels. A background of pines and silver birches lends a realistic touch to the scene.

A small rockery populated by dwarf shrubs, primulas, mossy saxifrages, Muscari Heavenly Blue, giving a fine blend of colour, is one of the features arranged by the Central Garden Supplies, Limited. The other part of the exhibit consists of two or three beds filled with early-flowering shrubs such as Forsythia intermedia and Prunus triloba, which are mingled with the brilliant colours of hardy azaleas and Rhododendron præcox. A new idea in window-boxes is also shown by this firm. These could be termed portable rock gardens. They can be made in any shape or size to suit all windows and crannies. They

Digitized by Google

are made of wood which is painted a remarkably true stone colour, and are to be had either lined with zinc or unlined. When filled with dwarf plants they have a very attractive appearance, and will give excellent service for a number of years even without a lining of zinc. From a decorative point of view they will prove of value in a house with many windows and odd corners.

Mr. George Whitelegg has fully attained his object in presenting a most realistic garden with a simple and effective yet formal design. There is nothing lavish or ornate in the design, with a pergola at one end, through which one catches a vista of a water pool with a fountain at the other end. On either side there are paths bordered by beds of early-flowering shrubs and hardy azaleas. A fine colour effect is obtained by the free use of red dwarf azaleas intermingled with taller plants of the brilliant lemon yellow Anthony Koster backed by evergreen shrubs such as cupressus and skimmias. The other bed contains some fine plants of Viburnum Carlesii of an ideal height and in full flower. It is undoubtedly one of the most attractive species in the genus, and visitors will realise its beauty when planted in a border, especially when it is allowed full play to exhibit its individuality, as in Mr. Whitelegg's exhibit. The full effect of this garden is obtained through the judicious arrangement of the shrubs and flowers and the formal design in the lay-out of the paths and beds.

An essential feature in any English garden of any extent is that part devoted to roses, and one always looks for its representation at an exhibition. At Olympia one is not disappointed, as a rose garden, complete in every essential detail and laid out to full size, is designed and exhibited by Mr. Reginald Winder. A series of terraces leading down to the centre of the garden form the chief feature. This, while being simple, secures shelter without the use of high screens. The beds of roses are kept in position by means of low brick retaining walls, which lend a pleasing touch of colour and should prove handy in providing a nook for creeping and trailing plants which will prove an added joy in spring before the roses are out. The main paths are of red brick, into which formal patterns of cobble are set, the whole arrangement being attractive and serviceable.

The scent of violets is always pleasant, and when tastefully arranged, as in Mr. Baldwin Pinney's exhibit, they provide an attractive feature. Beds of primulas and violets are set off to advantage by stonework and quaint figures supplied by the Leckhampton Quarries Company, Limited.

A MINIATURE ROCK GARDEN IN A WINDOW-BOX.

The St. Brigid strain of anemones is coming more into favour with the public these days, and Messrs. Reamsbottom's exhibit will do much to increase the popularity of these blooms. When planted out in formal beds, as this firm show, few flowers can compare with them for wealth and variety of colour. In addition, they are excellent for cut-flower purposes.

Messrs. Russell of Richmond show a choice selection of early-flowering and forced shrubs, such as camellias, acacias, azaleas and prunus, bordered by Primula The Jewel and the Lingwood variety. The exhibit loses much of its effect by being overcrowded and situated in a corner. It is always the tendency to crowd much into a little space, with the result that the plants lose their individuality.

In the centre of the hall, a garden of formal design is laid out by Clayton and Hammond, Limited, designed by Miss B. Colvin. A pool in the centre, with four plants of Skimmia japonica in fruit, with at one end two beds of bright-coloured primulas, add a certain attractiveness to it.

A moorland scene in the form of an alpine meadow with a pool nestling among banks of rocks forms the exhibit of Captain R. Crewsdon Day. Stretches of Cumberland turf with crocuses in small groups will attract the eye. These crocuses, however, had obviously been spaced by a foot rule. The heaths, such as Erica vagans and mediterranea, are also prominent; while saxifrages such as Sundermanni, Boydii, lingulata and frondosa, clothe what might be termed a rocky moraine. The trouble about this kind of garden is that it is next to impossible to cut the grass with a lawn mower; successful clipping is only accomplished by hand with a pair of shears.

An example of a garden formed of dry walls surrounding a paved octagonal court, designed by Mr. Ernest Dixon of West Hill Nurseries, Putney, could have been much more interesting and attractive by a more choice selection of early flowering subjects. Such plants as wallflowers are scarcely suited for dry wall gardening, especially since they were overshadowed by the surrounding shrubs, a feature that would be rarely seen in any outside garden. Included in the exhibit is a rock garden of a more natural design, filled with many dwarf shrubs and alpines.

SPRING FLOWERS AT VINCENT SQUARE

GRADUALLY, as the days come round and winter gives way to spring, the story of the change is fully evident on each succeeding occasion of the Royal Horticultural Society's Meeting. On March 10th last one felt like echoing the Geisha girls in the "Mikado" and singing of "the flowers that bloom in the spring tra la" on entering the hall. What a beautiful and wonderful display the spring flowers truly make with their charming soft and pleasant colours, and, above all, with that freshness which is the hall mark of the season. Alpines were well represented, including flowering shrubs suitable for the rock garden, carnations, orchids, cyclamens, roses, but undoubtedly the main feature was the exhibits of forced bulbs of tulips, hyacinths and narcissi which provide such an artistic show with a wealth of bloom and colour.

A striking display of hyacinths was staged by Messrs. Carters. Arranged in bold masses, as if they were bedded out, the whole group made a vivid patch of contrasting colours. The flower-spikes were long, the growth vigorous, and the colours bright and clear, those harsher in shade being softened down by the paler varieties. Duchess of Westminster, a purplish blue, and City of Haarlem, a cream, blended well together. All of the varieties were good, and to mention a few used, Dr. Leiber, Corregio, La Victoire, Lady Derby and Bismarck have been selected.

The seedling narcissi of Messrs. Barr and Sons again attracted much attention. Messrs. R. H. Bath were showing bulbs grown in fibre. Of this exhibit, the tulip Le Rêve was decidedly the best. It is a charming colour, a salmon pink slightly shaded with mauve and bronze at the tip of each petal, and is also good in shape and form. Messrs. J. R. Pearson and Sons, Limited, who exhibited an excellent collection of narcissi, had among them some beautiful white forms. The texture and purity were considerably above the average white trumpet narcissus. White Dame and Sanctity were both pure white and vigorous in growth. The drooping habit of the flowers of Sanctity was attractive. Some of the varieties although not perfectly white, were no less beautiful. Phantasy was creamy white with flowers on long stalks, and Capella had a very pale yellow trumpet surrounded by a pure white perianth. Mixed with any of these, the varieties exhibited with a deep orange cup such as Marshlight or Sunrise looked most effective.

A distinct patch of colour which caught the eye was that produced by the exhibit of Freesia Wistaria by Mr. G. H. D. Dalrymple, which decidedly deserved all the attention it attracted. The quality of the individual blooms was well seen even although they were arranged *en masse* with no varieties of other colours as a relief. The flowers were of a delicate shade of clear mauve, which merged gradually into lighter hues in the throat. The variety is, indeed, well named, as it is a true replica in colour of Wistaria chinensis. The flowers are of large size, measuring some 3½ins. long and almost 1¼ins. across, and as many as five to six individual blooms are carried on each tall and erect stem, which varies from 18ins. to 24ins. in height. The flowers also possess a sweet haunting fragrance. Wistaria certainly represents a great advance in the world of freesias, especially if it remains true and does not, as has been the case with many other varieties, produce a whole heap of "duds." For decoration and cut flower purposes it should prove of extreme value.

Digitized by Google

There was not a great deal new or noteworthy among the rock plants, but the benches were gay with the early wild narcissi, "blue" primroses and the many hybrids of Primula Juliæ. Of quite different charm is the lilac primrose (rather doubtfully called Primula altaica), which replaces the yellow form on the eastern fringe of its distribution. This was shown by Messrs. Prichard, who also exhibited a striking new saxifrage of their own raising—S. His Majesty—which is in effect a magnified S. Burseriana with glandular orange stems and a pronounced ring of brownish orange at the insertion of the stamens, both together giving a warm tone to the great white flowers. These are large enough to have sacrificed the neatness of a true alpine for a more ostentatious beauty. The parentage is interesting and unexpected, for the plant is a cross between the hybrid R. V. Prichard (S. Burseriana Gloria × lilacina) and S. lilacina, though the influence of lilacina shows only in the tightness of the rosette and a faint pink flush in the bud.

Messrs. Tucker of Oxford showed a good pink hybrid of Sundermanni in S. Arco-Valleyi, which is very like S. Jenkinsæ, but, perhaps, rather neater, and the petals are more overlapping. With it was shown Farrer's S. Myra, that probably owes its deep cherry red to S. Scardica (S. erythrantha). Tulipa Clusiana, perhaps the most graceful of all tulips, made its first appearance this year on the same bench. Its peculiar colouring—white, lightly marked with carmine outside, and carrying a central patch of blackish violet within—is perfectly set off by the slender grey leaves, and it is curious that such a beautiful and distinct tulip is comparatively seldom grown, for it is much easier than many of the species. Stylophorum diphyllum, with rough, divided leaves and poppy flowers of uniform deep yellow, was shown by Messrs. Waterer.

Among the other exhibitors were the following:

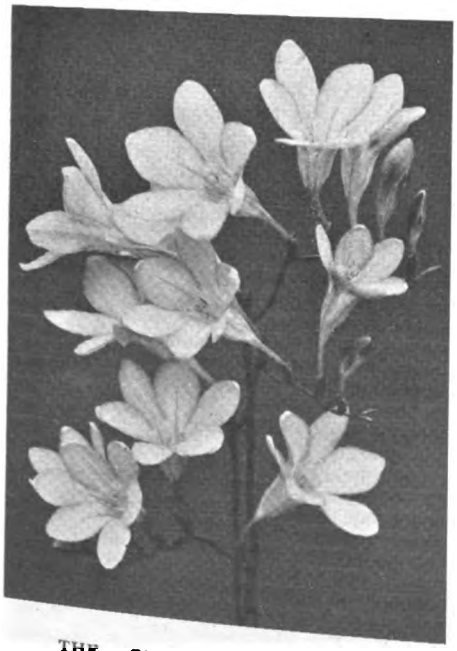
ANEMONES.—Messrs. Reamsbottom and Co., and R. Gill.

CARNATIONS.—Messrs. Allwood Brothers, C. Engelmann, and Stuart Low and Co.

CYCLAMEN.—Caledonian Strain Floriculturists.

FORCED SHRUBS.—L. R. Russell.

FRUIT.—Messrs. Bunyard, and Westmacott and Co., Limited.



THE OUTSTANDING FREESIA WISTARIA.

IRIS.—Messrs. Lowe and Shawyer, and Van Waveren, Limited.

ORCHIDS.—Colonel S. R. Clarke, C.B., Messrs. Charlesworth, Cowan and Co., J. and A. McBean, H. T. Pitt, Sanders, and Stuart Low and Co.

POLYANTHUS AND PRIMROSES.—Messrs. G. A. Miller, and K. and E. Hopkins.

RHODODENDRONS.—Messrs. R. Gill and Son.

ROSES.—Messrs. Elisha Hicks and George Prince.

SAXIFRAGES.—W. Wells.

SHRUBS AND ALPINES.—Messrs. Bakers, Barr and Sons, Carter Page, W. Cutbush, H. Hemsley, G. Reuthe, Skelton and Kirby, Waterers and F. G. Wood.

VIOLETS.—Misses Allan-Brown and Mr. Baldwin Pinney.

NEW AND RARE PLANTS.

NARCISSUS MEDUSA.—This is an excellent variety where the flowers are of good size and shape. The perianth is more or less whitish in colour, while the compact and cupped corona stands out in sharp contrast, being of an almost fiery orange shade. It is of a colour which is often associated with some of the best poeticus varieties. Award of merit by the Narcissus Committee. Shown by Mr. P. D. Williams, Lanarth, St. Keverne.

NARCISSUS GODOLPHIN.—Although this variety undoubtedly has merits as a garden flower, it appears to be eminently suitable for market purposes. It is a large trumpet variety of a rich yellow in colour. The perianth and trumpet are remarkably pure, and are of good substance and texture. The individual blooms are large and handsome, and carried well on long stems. Award of merit by the Narcissus Committee. Shown by Mr. P. D. Williams.

SALIX GRACILISTYLA.—This species is a native of Japan and Manchuria, and was introduced to this country about 1895. Judging from the naked shoots bearing catkins which were exhibited, it is of extreme beauty when in flower. The catkins, which are borne from now till April, vary from 1in. to 1½ins. in length and about ½in. broad. When unopened they are a silvery grey colour, being covered with a thick coating of fur. As they open the crimson anther heads dangle freely and loosely from the compact tassel and gradually assume a golden yellow colour as they become covered with their powdery pollen. Only the male catkins were shown. Award of merit. Shown by the Hon. Vicary Gibbs.

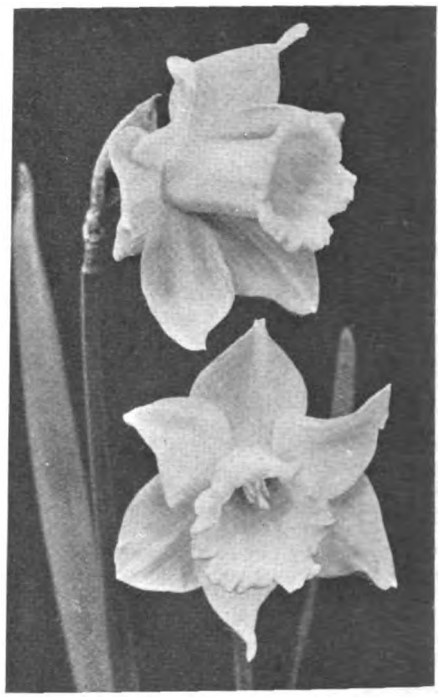
RHODODENDRON LEONARDSLEE GEM OF THE WOODS.—Fairly large pure white bell-shaped flowers, borne two or three together at the ends of the branches, are the characteristic features of this variety. The leaves are of a deep green colour and hairy on the upper surface. Award of merit. Shown by Lady Loder, Leonardslee, Horsham.

COLUMNEA BANKSII.—This is a representative of a genus of tropical American evergreen shrubby climbers which are excellent as subjects for decoration under glass. With their handsome scarlet flowers often, as in this species, almost 2ins. long, gaping at the apex, and their lolling, trailing or pendent branches bearing small opposite evergreen leaves they should be more generally known. Cultural commendation. Shown by the University Botanic Garden, Cambridge.

ORCHIDS.

MILTONIA BEAU BRUMMELL PITT'S VAR.—A charming form of this hybrid, the young plant bore a couple of flowers of purplish rose colour, the expansive labellum freckled with lighter spots. First-class certificate. Shown by Mr. H. T. Pitt, Rosslyn, Stamford Hill, London, N.

CYMBIDIUM FLAMINGO ROSEUM (Merlin × Alexanderi).—The erect spike carried four large flowers in which the segments were stiff and flatly displayed; in fact, the flowers had the formation of the well known Cattleya Loddigesii. Of blush rose tint, the labellum with light crimson markings on the front lobe and the column rose coloured. First-class certificate. Shown by Lieutenant-Colonel Sir George Holford, K.C.V.O., Westonbirt, Tetbury, Gloucestershire.



NARCISSUS GODOLPHIN, GOLDEN YELLOW

CYMBIDIUM BULLFINCH VAR. BRILLIANT (Alexanderi × Garnet).—The spike bore seven flowers of a yellowish hue heavily lined and suffused with reddish rose, the labellum whitish and with the front lobe of deep crimson. Award of merit. Shown by Lieutenant-Colonel Sir George Holford.

CYMBIDIUM MIRANDA, WESTONBIRT VAR. (Alexanderi × Lowio-grandiflorum).—This showy hybrid bore an arching spike of twenty-one large flowers of yellowish colour, the labellum white, and having crimson-red lines on the lateral lobes and a solid blotch of the same colour on the front lobe. Award of merit. Shown by Lieutenant-Colonel Sir George Holford.

CYMBIDIUM ALEXANDERI, OVERLEA VAR.—A robust plant of this well known hybrid, the two arching spikes bore a total of nineteen flowers of a pretty blush pink colour, the labellum having a few reddish markings and the column rose coloured. Award of merit. Shown by Messrs. J. and A. McBean, Cooksbridge, Sussex.

CATTLEYA JUPITUS (Edith × Tityus).—This elegant novelty bore two flowers with the segments broadly developed and compactly arranged, of rosy mauve colour, the petals crisped at the margin, the labellum having the large front lobe of crimson-purple. Award of merit. Shown by Messrs. J. and A. McBean, Cooksbridge, Sussex.

CYMBIDIUM TITYUS (Alexanderi × Woodhamsianum).—The long spike of this new hybrid carried several flowers of delicate creamy white tint, the labellum rendered conspicuous by the bright crimson markings on the outer margin. Award of merit. Shown by Messrs. Armstrong and Brown, Tunbridge Wells.

LÆLIO-CATTLEYA H. T. PITT VAR. SUPERBA (C. Enid × L.-C. Bella).—This promising hybrid had well formed segments of rosy mauve colour, the expansive labellum rich crimson and with a yellowish disc on each of the side lobes. Award of merit. Shown by Messrs. Flory and Black, Slough.

FENCES IN THE GARDEN

ALTHOUGH fences are mostly used to divide one person's property from someone else's, they nevertheless find extensive application for dividing different portions of the same man's garden from each other, and also for keeping out livestock and trespassers from the garden itself when they are used to divide it from meadows, etc., or when a public footpath or roadway runs along one or more sides.

What type of fence shall we use, and shall we employ a fence at all, or build a boundary wall? In these days wall building is a very expensive matter indeed, and in most cases quite out of the question. Fences, therefore, of one sort or another must be employed.

WATTLE HURDLES.—These are among the most useful of economical fencings. They are cheap, light, easily erected and easily moved, and additions or renewals are quickly made. If strengthened with strong stakes they make an admirable background for climbing plants. Although not so lasting as an oak paling, they stand the weather long enough for all ordinary purposes. They are invaluable for temporary shelters for rare and delicate shrubs, and an enclosure of a few square feet is put up or removed in a very few minutes. The shelter they afford from cold winds is undoubtedly considerable, and a few of these erected across the exposed side of a plot planted with early potatoes will make all the difference, as will be quickly found, between the crop getting nipped and growing away unchecked. Likewise, for seedlings, etc., for which a cold frame cannot be spared during the springtime, wattle hurdles will be found useful, as the wind will strike them and pass over the seedlings themselves instead of striking the soil in which they are growing.

When not required for use for a few months wattle hurdles are easily packed out of the way under any old roof that is available. They must, however, be kept as dry as possible when in this store, otherwise they will quickly perish and become more or less useless.

IRON FENCES.—For more elaborate fences or where absolute privacy is required, iron fences are much in demand. Owing to the cost of building walls of brick or stone, iron spiked palings are a good alternative, while on many estates iron paling posts are preferred to wooden owing to their lasting qualities. The same applies to gates made of iron or other metals, while, of course, wrought iron gates, often copies of old designs, enhance the beauty of the entrance to a garden.

WOODEN FENCING.—When a close fence is required, whether to maintain privacy, or for any other purpose, close boarded oak fencing is to be recommended. This is strong and very durable, provided, as goes without saying, that the wood is well protected with some chemical compound, such as creosote or thoroughly painted before it is erected. This is supplied by fence-making firms in heights ranging from 3ft. to 6ft., and the price per lineal yard is remarkably cheap, considering the high cost of everything nowadays.

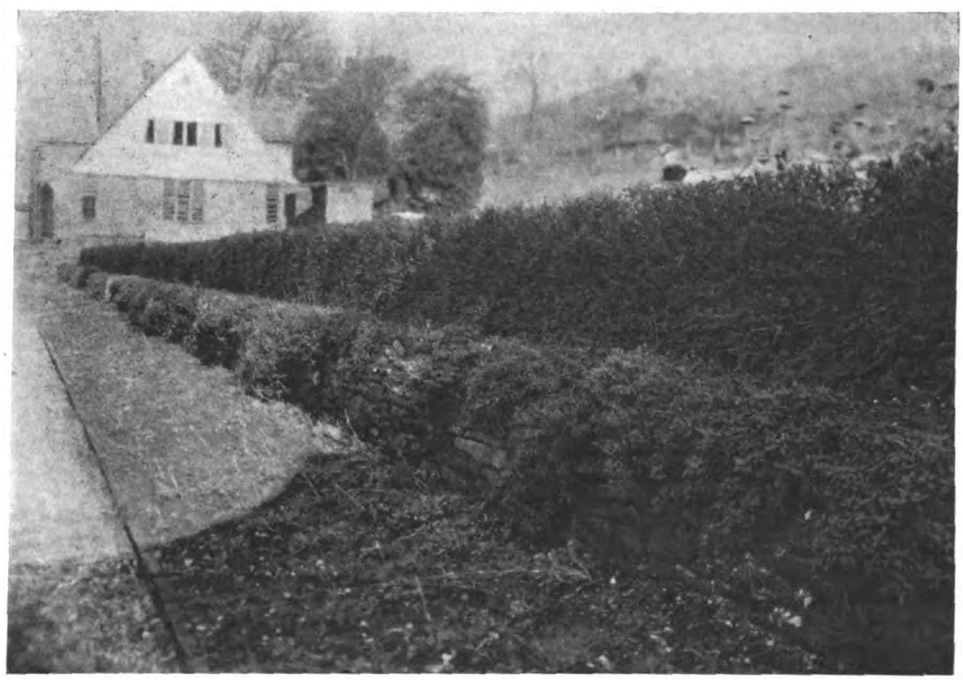
When a pale fence only is to be used, cleft chestnut is recommended, but other good woods include larch, fir and pine. The two principal types of this consist of fencing with the pales of even height, and fencing with the pales of two or more different heights. Obviously, if the whole fence is of an even height it is stronger and less easy to break down, and this is, therefore, recommended in preference to having say a 4ft. fence of which every other pale is only a yard in height.

Paling fences generally have the individual pales wired to each other in two, three, or more places, the ends of the wires, of course, being wound round or stapled to stronger posts at intervals. Where an extra strong paling fence is required it may be worth while to carry a wooden bar along the top of the row of palings, nailing through this into each, and also a second or third bar at a suitable position part of the way down.

WIRE FENCES.—These are not, as a rule, very beautiful, but they are certainly durable. A large range of meshes and gauges is available, the two most favourite forms being the diamond mesh and the square mesh. A leading manufacturer informs me that there are now on the market about a hundred distinct combinations of gauge and mesh. Thus a wire fence can be adapted to almost every requirement.

The height of wire fences must obviously depend, as in every other case, on the purpose for which they are to be employed. From 3½ft. to 4ft. is a favourite one, but for really substantial protection a fence 6ft. in height, with the top well barbed, is desirable. Strong wooden or concrete posts have to be inserted at intervals, and care should be taken when erecting to keep the wire as taut as possible. Straining pillars have, obviously, to be inserted at each corner, but for long, straight fences one of these in every hundred or hundred and fifty yards will be quite sufficient. Attachment or intermediary posts must be allowed for at the rate of about eight per hundred feet, or closer in certain special instances.

It may be mentioned before leaving the subject of wire fences that more effort might well be made to beautify them during the summer months by planting climbing annuals along their inner sides, provided, of course, that these are not of a poisonous character, or likely to injure stock which may eat them from the other side of the fence.



A CLOSE CLIPPED HEDGE OF LONICERA NITIDA, FORMED OF PLANTS THREE YEARS OLD.

LIVE FENCES.—Just a word in conclusion about live fences of privet or other shrubby subjects. These are sometimes used in connection with barbed fences or pale fences, but are not very often used when wire is employed. Personally, I should never advise planting privet on account of everybody having a privet hedge in their garden. Golden privet, however, is well worth considering because of its greater attractiveness; while holly makes a very thick and quite impervious hedge. A new and choice evergreen which is now coming to the fore as a suitable plant in forming live fences is Lonicera nitida. Poisonous shrubs, such as the yew, should not be used on account of the danger of cattle eating them, or the clippings becoming mixed with food for livestock accidentally. If live fences are to be planted this season the work must be done immediately, as it is getting late.

E. T. ELLIS.

SEED SOWING

BY EDWIN BECKETT.

A WELL behaved seed packet generally bears some such instruction as "Sow on a warm site in April," or "Sow in drills in May," and it all appears very simple; but these notes must start with a query as to whether it is quite so simple as it seems at first glance. Those to whom seed sowing is a comparatively rare occupation may well hesitate before replying, but those accustomed to the work will no doubt answer most emphatically in the negative. That may well be understood, for more seed is probably wasted through poor or bad sowing methods than from any other reason. Incidentally, this survey of the art may save many an innocent seedsman from blame because "seeds won't germinate."

In order to introduce the subject, we will consider what a seed is, and how it functions towards the production of plant life. It is just a small body containing what is really a microscopic plant, termed the embryo, and a quantity of food material, though at times this constituent is missing, the whole being encased in a coat of greater or lesser strength. From this the living embryo under certain conditions escapes to produce the mature plant in time. When germination commences, the primary parts which will ultimately give rise to root and stem are thrust forth from the seed vessel—the root portion going downwards, avoiding the light, though air is necessary to it, while the other part thrusts upwards towards light and air, and eventually becomes the stem of the plant. Moisture, temperature and air are the governing factors that control germination, and these facts now bring us to the prime essentials for a commencement of seed sowing.

The first point to remember is, never to bury the seed too deeply in the soil so that the tiny plant is stifled and destroyed before the stem portion can reach the air and light, so necessary to sustain life. Often the food supply within the seed is exhausted in the attempt of the stem to reach above ground level. This deep sowing is a frequent error, and one that can be avoided by bearing in mind an everyday rule: only to cover a seed by its own depth of soil. This is a "rule of thumb" method, not a hard and fast one, for some seeds are so fine that they only need sprinkling on the surface of the soil of a seed pan and to be pressed into contact with the soil, but, generally speaking, it is a safe and good rule.

The second matter to observe is never to sow in hopelessly wet soil, in which case one would only expect the seed to rot before it would germinate, and to avoid sowing, whenever possible, at such time as the temperature is so low that it would only retard or even prevent proper germination.

Another detail that should be properly observed is to have the soil in good tilth, *i.e.*, sufficiently broken up to receive the seed in such manner that air is present to aid the germination. The Biblical parable of the sower and the seed is probably one of the finest lessons on this point and others that any gardener could wish for in illustrating the matter.

One very important consideration always to bear in mind is to avoid sowing too thickly. It is of more importance than may at first be imagined, and to emphasise the lesson and drive it home we must parallel the raising of seed with human life. The crowding together of human beings in confined areas is a prime cause of stunted growth, ill-health and disease, mainly through the lack of sufficient light and air, and also partly by the absence of proper food and protection. Such is the case with young plants grown in overcrowded conditions. The dreaded damping-off disease (Pythium de Baryanum) of plants, for instance, is a frequent result of thick sowing and too damp a seed-bed, and there are other diseases which affect plants that are encouraged by such adverse conditions.

SEED PAN OR POT SOWING.—Pans or pots should be perfectly clean, both within and without, and drainage is the most important item after that. A stopper of broken crock should be placed in the bottom, surmounted with lesser pieces, and finally finished with smaller crock, over which should be placed a good-sized piece of fibrous turf. The general idea of the "crocking," as it is termed, is that for seed raising two-thirds of the space should be occupied by crock. This is all very well if the young seedlings are to be transplanted as soon as they are ready to handle, but if there is a likelihood of such an operation being delayed for a time, lesser crock should be employed to permit more compost, in order to sustain the life of the young plants until they are moved and to lessen the call for water, such as would be the case if only a shallow depth of soil is in the pot. On this point, of course, the sower must use his discretion. Finally, on the turf layer place the compost so as to fill up to within a half-inch from the rim when sufficiently firmed down, which operation should be done with the finger-tips. The idea of the latter is to obviate layers of soil, packed down firm, on which another layer is spread and packed, as this leaves a crevice-like division into which the seedlings have a tendency to pack their young roots rather than to spread them out evenly downwards in the soil. When seeds are sown, such as peas and beans, in pots where they are to grow on, the foregoing rules require modification as to the depth from the rim, for in such cases sufficient space must be left for top-dressing the young plants as growth is made, so that they do not get starved. Other details, such as soil covering, watering, etc., are controlled by the early remarks, and it only remains to add that the compost used should be of a nature and sufficient fineness to suit the seed sown and moist enough for the purpose. When the seed is sown, should it require watering, careful immersion in water is far preferable to watering with a can and rose, as the latter method, especially with regard to very small seeds, is likely to disturb them badly. Remember to sow evenly and not too thickly. Sand should always be a constituent of the compost, for this is the medium in pot raising that allows the necessary air to penetrate to the roots of the young plants as well as rendering the compost porous.

SOWING IN DRILLS.—This method is adopted in frames and for the open ground in cases where it is desirable to grow the plants under proper control and where transplanting is not desirable for the crop as it stands. It is the principal method for open-air work and, incidentally, effects good saving of seed in the majority of cases. The drills should be drawn in lines running north and south for preference, so that plants are permitted to have the influence of sun on three sides, whereas were they drawn east to west only one side would be principally affected. The drills should be drawn in a surface of fine tilth, and only of sufficient depth to allow the seed to be sown in conformity with the previous advice of not burying too deeply. Seed should be sown thinly.

BROADCAST SOWING.—In these days of wireless, very few people but know the meaning of broadcasting, and when applied to seed it still only means spreading in all directions. This method is principally used for seed-beds, where such items as the brassicas, leeks, celery, etc., suitable for transplanting when required into rows in other quarters, are sown. The only notes on this that are required are again to advocate the surface of the soil being of fine texture and to renew the advice against sowing too thickly. Further should be added a caution to protect against attacks by marauders, such as birds, mice and other seed raiders, by means of nets and other devices when the sowing is completed. This is necessary in all cases, and it is also necessary to protect the young seedling plants against slugs, which may effectively be done by ringing round them with sharp cinder ash.

Little more need be added to this subject other than a caution to thin out seedlings at an early stage so that they do not get overcrowded, with the resulting "drawing" effect, and to mention that when the transplanting period arrives and the plants are being moved from their nursery quarters this should be done in a careful manner so that as much soil as possible is left in position round the roots in order to prevent root disturbance as far as this is possible. Transplanting is an art that only careful practice will teach.

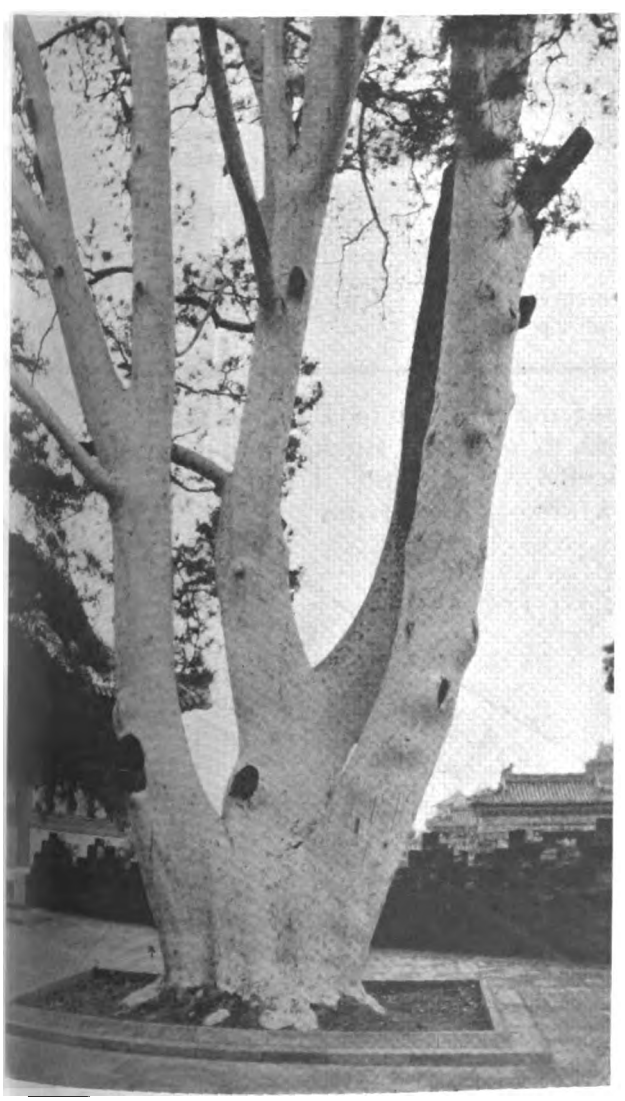
CORRESPONDENCE

PINUS BUNGEANA.

THE accompanying illustration of Pinus Bungeana, the lace-bark pine of North China, was reproduced from a photograph given to me by a lady who has just returned from Pekin. It represents a tree growing in the environs of that city, and gives, I think, an excellent idea of the most prominent characteristic of this pine, which is, of course, the conspicuous whiteness of its trunk. This character, unfortunately, does not develop until the tree has attained a considerable age—at least fifty years, I believe—and no tree in cultivation in this country has shown it yet. The species, nevertheless, is thriving well, and at Kew there is a group of healthy trees in the pinetum at the south end of the lake. Apart from the white trunk, which we shall have to wait for, Pinus Bungeana is well worth growing. The best grown young trees assume a pyramidal form; others make large, rounded bushes. I remember the late Philippe de Vilmorin told me he considered there were two natural types of this tree distinguished by this difference in habit. Both are well furnished with vivid green foliage and are ornamental enough to be planted by all who take an interest in conifers. This pine is quite at home on a limestone formation. Its leaves, in bundles of three, are about 3ins. long, the basal sheath soon falling away. The onlyother pine closely related to it is the very rare P. Gerardiana from the Himalayas. The cones, each 2ins. to 2½ins. long, with scales armed with a decurved spine, have for several years past been borne by trees at Kew.—W. J. B.



PINUS BUNGEANA WITH ITS CHARACTERISTIC WHITE BARK.
(From a photograph taken in China.)

BULBS IN THE UNITED STATES.

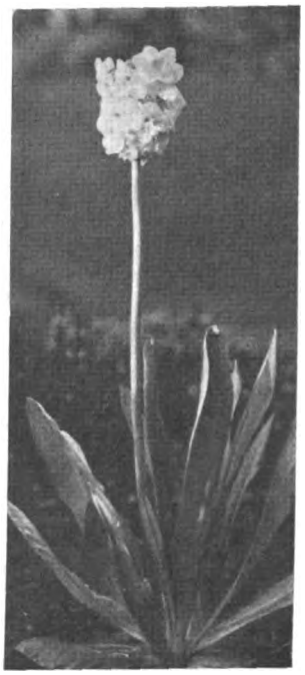
SIR,—With reference to the recent embargo on potatoes from the United States, if Great Britain and other countries would issue a few embargoes against agricultural products, we, in the United States, who are interested in the importation of bulbs are inclined to believe that some of the arbitrary features of Quarantine 37 would be either lifted or would be tempered with common sense.

Our Department of Agriculture has given the growers of narcissi in the United States three years in which to accomplish and master an undertaking which has taken European bulb centres over 300 years to become proficient in, and this period of three years ends with December 31st, 1925. This act alone is inconsistent, because anybody, even our Department of Agriculture itself, can point out in conclusive evidence that narcissi cannot successfully be grown in the United States on a commercial scale.

It has been suggested among the importers of bulbs in the United States that they would be willing to pay an extra 2 dollars per thousand on imported bulbs for inspection and treatment fees; this in addition to the 2 dollars duty that has to be paid in any case. This inspection and treatment would be in addition to that required in the packing of shipments in Europe. At the present rate of importation, duty and inspection fees would yield 400,000 dollars per annum. If every importer of narcissi had to consign his shipment to New York for treatment and inspection, I am satisfied in my own mind that all narcissi imported into the United States could be inspected and treated for 25,000 dollars per annum.

Horticulture in this country is of no importance when compared with agriculture, which makes it exceedingly difficult for the horticulturist to get a hearing, while, on the other hand, the protest of the American farmer is immediately carried into the Senate and Congress. The five members constituting the Federal Horticultural Board are vested with power—through the Secretary of Agriculture—to employ such means as will safeguard agricultural and horticultural interests in the United States, to promulgate and put into effect from time to time such embargoes and quarantines as they, in their judgment, see fit, often with practically no thought for the interests of commercial growers at large.

We fumigate our cotton before it leaves the country in order to guard against the spread of the boll weevil, and this fumigation is absolutely satisfactory. Because this is possible, we who are interested in narcissi see no reason why the bulbs should not be imported subject to rigid examination and treatment before being released.—DAFFODIL.



PRIMULA CHIONANTHA.

A VALUABLE FLOWERING PRIMULA.

SIR,—Everyone who can grow Primula chionantha successfully will agree that it well deserves the award of garden merit conferred on it by the Royal Horticultural Society. In the R.H.S. Journal note mentioning this award the time of flowering is given as June and July. I cannot understand this, as my plant last year flowered in May, and things with me are a fortnight to a month later than in the south. Also I noticed it flowering in the Edinburgh Botanic Garden about the middle of May. My plant behaved rather curiously last year, for after flowering well in May—as the enclosed photograph shows—it lost all its leaves and went to rest in August, but started growing again in October, and had two fine flower spikes in November. After this it again died down, and now on February 5th it is starting into growth again. It was not alone in flowering in this way for a second time last autumn, as Primula muscarioides and P. Littoniana did the same.—R. B. COOKE.

ROSE TRIER.

SIR,—I am much interested in two letters in THE GARDEN referring to Rose Trier. I have "inherited" a climbing rose which is labelled "Trier." It is a strong grower with brownish stems, flowers freely, bunches of small pinkish white blossoms, no scent, and it ripens brownish green hips. I should be grateful if either of your correspondents will tell me if it is true to name, or has Trier died and only the stock remained?—M. M. S., *Bath.*

SIMPLE GARDENING

MIGNONETTE.

THIS tiny-flowered plant does not require any recommendation; it is one of the most widely known of all garden annuals, but, even so, it is not generally well cultivated. Usually, a few seeds are sown thickly in rows or patches in the borders. The resultant seedlings are rarely thinned out, but all, or nearly all, bear small stems with a few tiny flowers in a bunch at the top. The plants, in wet weather, are beaten down and many rot on the ground. There is, of course, the medium treatment with corresponding improvement of flower and plant. The mignonette grows well, and forms a strong plant, in a pot as well as in the open border. With a little extra care fine standards may be grown. There are some beautiful varieties, seeds of which are advertised by seedsmen in THE GARDEN. Having made a selection of these the cultivator should duly prepare a plot of ground in which to grow the plants in rows for cutting and in clumps in the border. A medium rich soil is the best; in poor ground the plants are thin and wiry; in very rich, they are too strong and sappy of stem. Some old mortar rubble will improve the rather rich soil. Sow the seeds thinly, watch the seedlings carefully and duly thin them to at least 3ins. apart. Before the plants entirely cover the ground scatter some leaf-soil and loam, mixed, between them. Fine masses of plants will result, bearing big spikes. If grown in pots for the windows or greenhouse, sow several seeds in small pots in frames, thin the seedlings to two in each pot and re-pot in due time. Do not transplant; 6in. and 7½in. pots are suitable for final potting.

CELERY SEEDLINGS.

Celery is one of the most difficult of our many kinds of vegetables to grow. Undoubtedly, the young plants can be grown grossly if they are subjected to a strong bottom heat, but this treatment would be wrong. I remember seeing a box of fine-looking plants on a hot-bed many years ago, when I was a youth. A gentleman who saw them remarked on their splendid condition. But at the end of the season they were failures, possessing big but hollow stalks. A noted judge once referred to some large sticks staged, as overgrown. Celery plants should never receive a check, but be grown on steadily and in firm, rich soil when the trench stage is reached. It should be remembered that celery plants are gathered as bared in the ridge of soil, a start being made at one end of it. All the plants should be of the same size as nearly as possible, and to ensure this being so seedlings of similar size should be transplanted in the first case. The work of transplanting should be done timely at each stage, first at 2ins. apart in boxes 4ins. deep containing about 3ins. of loam, leaf-soil and a very small proportion of well rotted manure. A greenhouse shelf is an ideal place at first, then a cold frame. In the meantime, a bed should be made in another cold frame or a sheltered position outside. Put down a layer of sifted ashes 1in. deep, firm these with the back of a spade, then add a thin layer of rotted manure and follow with one of good compost 4ins. deep. Plant the celery 6ins. apart. In due course they can be lifted and planted in the trenches with all the soil adhering to the roots, and no check will occur.

PREPARING PLANTS FOR WINDOWS AND HANGING BASKETS.

Very frequently, plants are taken direct to a dwelling-room window without any previous preparation. The result is that, in such cases, the plants are unsatisfactory throughout the whole of the summer. There are, in the majority of dwelling-houses, windows facing north, east and west. Of course, some kinds of plants do better in cool than in hot windows, and so it is a wise plan to study this matter and provide the kinds of plants most suitable to the various aspects. For example: ferns do best in east, north and north-west windows. Zonal pelargoniums, petunias, nasturtiums and marguerites do well in a hot window. For hanging baskets, naturally drooping plants such as ivy-leaved pelargoniums and fuchsias are suitable, and tiny plants such as lobelia are for all window boxes and baskets. Persons who own greenhouses should re-pot selected specimens that are to be grown in pots throughout the summer, and get them nicely established in the pots before they are placed in the windows. Other plants that are to furnish baskets or window-boxes should not be allowed to become pot-bound before they are placed in their summer positions. Purchased plants should all be up to the standard required for the various purposes.

EVERLASTING FLOWERS.

These are very beautiful and interesting flowers and are grown more carefully now than they were a generation ago. In favourable seasons most of the varieties may be raised from seeds sown in the open borders in the southern counties. But it is well worth while raising seedlings in boxes and transplanting them, in due time, to their flowering quarters. If seeds are sown thickly outside and the resultant seedlings are not freely thinned-out the flowers are very poor ones. A few plants well treated will surprise the cultivator by their beauty. Use the following ingredients for a compost: Loam, 2 parts; rotted manure, 1 part; and leaf-soil, 1 part; sand is not required. The soil in which the plants are flowered should be deeply dug and also well manured. The planting should be done the third week in May. The flowers should be gathered, made into small bunches and suspended, heads downwards, in a cool, dry shed, when they are three-parts open. So suspended the stems retain their position. The best way to use the flowers in the winter is to form bouquets by inserting the stems in soft lumps of clay, the latter dry and the bouquets may then be placed in vases in the dwelling-rooms and halls. The helichrysums are all richly coloured; the rhodanthe, purple and white respectively, is really exquisite; Statice Suworowi, annual, and S. latifolia, perennial, are also charming. These are the best to grow. GEORGE GARNER.

NATIVE PLANTS

WITH the approach of spring everyone gets a touch of wanderlust. Whether it drags us overseas or to a nearby hedgerow we have an earnest desire to explore, and the result of such exploration is usually the collection of a plant or plants. Of wild plants from abroad I have nothing to say at the moment except that at the right season you can see hardy townsmen arriving any evening at Victoria each bearing parcels of varying shapes and sizes. From the jealous care which is shown to these parcels one would imagine that they contained the latest creation from Paris or a seasick baby; not at all, they are the result of strenuous days in the mountains, of hours of climbing, of digging with a trowel, of trouble with the Customs. They are alpines which can usually be bought for a shilling or two a dozen from a nurseryman.

Perhaps I am a little unkind in speaking in this way, for after all a plant which you have collected with your own hands is worth dozens of bought plants. Their sentimental value is great. Many of these plants collected in the hills on the Continent will thrive with ordinary care. Very different is the case of most wild plants in the British Isles. Many of these, in fact most of the smaller native wild plants, prove exceedingly stubborn in cultivation. Take Lords and Ladies as an instance. In many parts of the country it is exceedingly common, but try to transplant it to surroundings where it is not found in a wild state and nine times out of ten it will be as stubborn as a mule and refuse consistently to thrive or to spread.

It is often said that enthusiasts who comb the country in order to find our rare native plants are jealous by nature. They will produce some prodigious rarity and refuse to tell their best friend where they found it. The reason, no doubt, is partly that the plant is really very rare and they realise that if they describe its habitat the supply will rapidly be exhausted; but there is another and, I think, far more sound reason, and that is that the plant is obviously by nature difficult, else it would be found in greater quantities as a wild plant. If it is miffy in its native state, it is obvious that it would be a terror to grow in a garden and so perhaps it is better to leave it where it is.

I should say that our native plants are the most difficult to grow successfully in gardens, followed by those from the Rocky Mountains as a close second. The third would probably be New Zealand plants. By this, of course, I mean plants from areas where the climatic conditions are either the same or more severe than at home. On the other hand, the percentage of plants from the European Alps or from China which are cultivatable must be large.

No doubt there is some scientific explanation for the miffiness in cultivation, particularly of our native alpines, but I think that this can be explained in simple terms. It is largely a question of food. Supposing that a human lived and thrived under meagre conditions and that suddenly his food was altered while everything else was kept the same. Instead of 8oz. of nourishment being assimilated every day, his interior economy was called upon to digest 2lb. of richer food every day. For a period there would be great internal derangement. The average life of a human is from sixty to eighty years, while of a small plant it may be as many months, and their internal adjustments are just as complicated as those of an animal.

It might be imagined that plants from abroad would be liable to derangement to an even greater degree, but I think that is not so, for in the case of native plants only one factor is really altered, that of richness of food, while those from abroad have to approach life from a different angle in many details. It is often easier for a human to change his entire method of existence than to alter it essentially in only one detail.

This may appear to be a feeble explanation of the difficulty of growing our native plants in our gardens, when all the various factors and exceptions are taken into consideration, but I think there is a modicum of truth in it. One thing is certain, that the rarer a native is in a wild state the more difficult is it to acclimatise in our gardens.

I have not touched upon the ethics of growing native plants in our gardens, as this is a question on which opinion is divided. Personally, I can see no objection to it other than the fact that the majority of them grow better in their native haunts, but there are many gardeners to whom the cultivation of our rarer natives is anathema. I suppose it depends upon whether we look on our gardens solely as a collection of plants or as a spot which is peaceful, and where our senses are rested and satisfied. Apart from the question of plant collecting there is an infinite joy in looking for and examining plants in the wild. It is just as satisfying to see a fine group of Dryas octopetala in full bloom on the Scotch hills as it is on the Alps. There are many places in this country which have a magnificent flora, and yet they are only known to a few enthusiasts, and of these most of them look but do not touch.

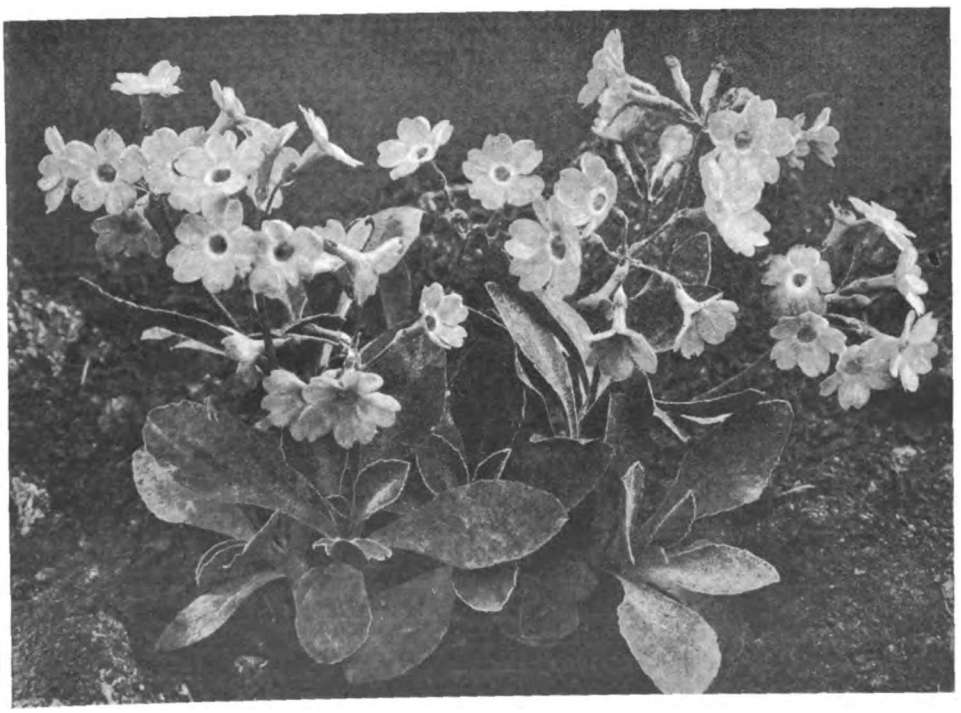
EUROPEAN PRIMULAS

THERE ARE FEW PLANTS SO PLEASANT TO GROW AS THE PRIMULA, AND THOSE OF THE GENUS WHOSE NATIVE HABITAT IS THE EUROPEAN ALPS ARE AMONG THE MOST SATISFACTORY OF ALL FOR GARDEN PURPOSES.

IN PRIMULA MARGINATA we have a most pleasing and satisfactory subject for the rock garden, sound and reliable in every respect, ranking among the best, and is worthy to, and should, be included in every collection of good alpines.

PRIMULA FARINOSA, THE BIRD'S EYE PRIMROSE, A DAINTY SUBJECT FOR THE ROCK GARDEN.



THE ATTRACTIVE VIOLET PURPLE FLOWERS OF PRIMULA MARVEN.

There are, of course, a great many forms of this charming plant, colours varying in all shades of lavender, lilac, purple and violet, and rarely white; the size and shape of individual blossoms also vary considerably, some being large or small, starry or round, but, generally speaking, all types are good. The foliage is of a stout leathery texture and is formed into sturdy rosettes which sit tight on the woody ancient-looking stems, so characteristic of the plant. In the early spring as the new leaves unfold, the plant presents an extremely handsome appearance, being practically enveloped in thick cream-coloured meal, this being particularly distinct on the margins of the beautifully notched leaves, and although heavy rains wash the greater part of the meal away, the bold white margin still exists. If the plant is grown in the alpine house the mealy appearance is more or less preserved. The flowers are borne in May and June on 3in. or 4in. stems, several blossoms constituting a head. Its culture is of the simplest type, it being perfectly happy in an ordinary, gritty, well drained compost, preferably where it can enjoy a choice, sunny, perpendicular crevice, but it will grow and thrive in any ordinary sunny pocket. Although it prefers lime this substance is by no means essential for its well being. It has many stations in the European Alps, occurring both on limestone and granite formations. As time goes on it will be found that the stems get rather straggly and somewhat unsightly. If the tops are cut away, however, fresh buds will break in plenty down the old stems, and the tops will root readily in sand and provide new robust young stock.

PRIMULA MARGINATA VAR. LINDA POPE.—This variety, which may possibly be a hybrid, is one of the finest forms of the type. It possesses all the good qualities of P. marginata in an enhanced degree, rendering it an ideal plant for the alpine house. Comparatively little difficulty ought to be met with in its cultivation, provided it is treated like the type. Of late years it has become very rare, and nowadays can only be procured from a limited number of nurserymen. Style and habits favour P. marginata, although the leaves are much larger, and more deeply notched; while the flower stem is more sturdy with a dense head of large sumptuous blossoms of a lavender colour with a mealy white eye. The blossoms are as round as could be desired.

In PRIMULA × MARVEN we have another plant of great reputation and one that is often sought for in vain, since it is now as rare as Linda Pope. One parent of this delightful hybrid is P. marginata, but I do not think it is possessed of foliage quite so handsome, although it is well powdered with farina, and is sturdy and compact. The flowers are very attractive, of a violet-purple shade, much enhanced by their conspicuous pure white eyes. They are also freely produced in heads, the stems of which just appear above the foliage. It is a good doer in a well drained compost in a cool corner.

PRIMULA FARINOSA (the bird's eye primrose), is indigenous to Britain, and is a dainty little subject for the rock garden or for naturalising in grass, to which it is accustomed. For association with other plants in the alpine lawn it is also ideal, or planted with Myosotis rupicola it provides a splendid combination of colour. As the name implies, the plant is wholly

Digitized by Google

covered with farina, which gives its foliage and flower stalks a silvery grey appearance. The leaves are formed in the shape of a dwarf rosette, sitting close to the ground, and are long and narrow, while the flower stalk varies in length, from 3ins. to 6ins., headed by a group of delightful pale pink golden-eyed flowers. Colours do not differ to any marked degree. Sometimes one may pick out an extra deep coloured specimen or a much paler form, or even, very rarely, a pure white one, but none is prettier than the usual type. As regards its position on the rock-garden, a sunny aspect is suitable, in a compost of good turfy loam, well drained, and where its roots are cool. Plant among other dwarf alpines to obtain good results. It flowers about May or June and sets abundant seeds, by which it is propagated.

PRIMULA SCOTICA.—Simply the Scotch form of P. farinosa, but not so satisfactory to cultivate, very often dying out after flowering. I think it sometimes flowers so much as to kill itself. Only this last summer I noted odd plants that produced three distinct crops, and on each occasion ripened all their seed. The grey, powdered leaves are short and broad and the deep purple flowers are borne in heads on 2in. stalks, making the plant a perfect miniature of the type. Treatment as for the latter.

PRIMULA LONGIFLORA.—The beautiful species that has a wide distribution, in the European Alps occurring in the high alpine meadows. It resembles P. farinosa, but its rosy pink or lilac flowers are larger and the corolla tube is very much longer. The leaves are very similar, being pale green covered with meal, but slightly larger. Position and compost as for P. farinosa.

PRIMULA HIRSUTA is an easy and free-flowering alpine that is capable of making a showy patch of colour in a choice corner in the rock garden fairly rapidly, producing short, sturdy tufts of leathery leaves which are densely covered with fine brown hairs, more noticeable perhaps round the serrated leaf margins. The flowers appear in heads just above the foliage, or may even be snugly nestled among the leaves. Again there is much variety in colour, but usually rosy pinks predominate, albinos rarely occurring. A nice sunny pocket or crevice in a well drained mixture of loam and leaf-mould will be found quite satisfactory. It seeds readily, and numerous first-rate hybrids have been derived from it, one of the best being

PRIMULA HIRSUTA MRS. J. H. WILSON, which made a splendid new addition for the rock garden a few years ago, having the same free-flowering qualities, together with a sound and hearty constitution. The flowers, borne in May on heads on 3in. stems, are of a bluish-purple colour, with a white eye. The foliage of all the hybrids is more or less alike, and cultural details also. It may be noted that although a sunny position is advised, a cool root-run should also be provided. Other noteworthy hybrids include P. h. Ruby, of a ruby red shade with an eye of purest white; P. h. The General, with flowers of an uncommon shade of a rosy terra-cotta; and P. h. Ladybird with mealy leaves and flowers of a dull red, the heads carrying them being exceptionally large and round.

PRIMULA PALINURI belongs to the auricula group, but seems rare in cultivation. Its leaves are large, smooth and of a bright green colour, and it increases from a rambling woody rhizome. The flowers droop in loose heads, similar to cowslips, and take the form of golden yellow trumpets; these, by the way, are sweet scented. For the rock garden it needs a sheltered position, facing west, and delights in a warm limestone crevice, in loam and peat.

PRIMULA AURICULA CILIATA is a very dainty and choice species, desirous of a well drained sunny ledge in the rock garden, in a gritty limestone mixture. It is small and neat in all its parts, having leaves of a dull green, covered with minute silky hairs, giving them a smooth, velvety appearance. The flowers are bright yellow and hang loosely in heads on short slender stems in June or thereabouts. F. BARKER.

(*To be continued.*)

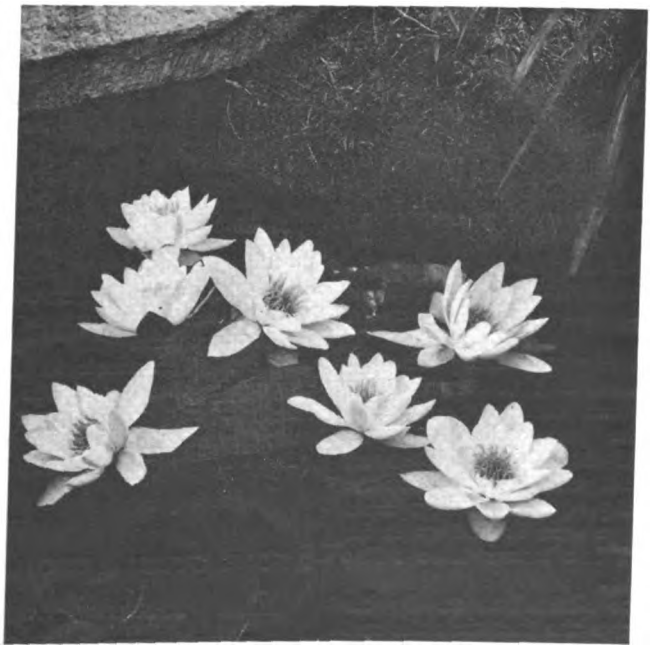
PLANTING THE WATER AND BOG GARDEN

(*Continued from page* 159.)

THE mention of foliage by the waterside introduces a note that is one of the essentials for success in such planting. Broad, massive foliage shows to better advantage by the waterside than anywhere in the garden, and the noblest genus for the purpose is the gunnera. The Chilian species, G. scabra, is the one most frequently met with, and is a plant of noble proportions, but G. manicata grows larger, and where it can be planted should be used. Both require plenty of room and should never have any other vegetation crowded close to them. As they have been known to attain a size of 20ft. or so across and their bold, handsome leaves sweep right down to the ground, it is obvious that other plants have little chance in competition with them.

The rheums, or ornamental rhubarbs, are also effective and bold. R. palmatum sanguineum with its crimson veins and giant foliage is always beautiful, but is never so attractive as when its towering spikes are rising 6ft. or more, delicately tinted amber, soft green or vivid scarlet, sometimes all three at once.

Then there are the rodgersias with leaves like the chestnut and flowers of various tints, the best of which are R. æsculæfolia, pale pink; R. pinnata, deep rose; and R. tabularis, creamy white. All prefer shade and love moisture.



WATER LILIES THE REAL GEMS OF THE WATER GARDEN.

Before leaving the large foliage plants I must mention Saxifraga peltata (giant saxifrage). Delightful pink flowers rise from the ground in early spring before the leaves develop, but the true beauty lies in the succeeding foliage. Three feet high, beautifully veined and netted, this is one plant I would always have in the water garden to the exclusion of many others. It is equally happy in shade or sunshine.

But despite the nobility of the bolder-leaved plants, the water garden would never be the fairy land it can be without its sedges, rushes, reeds and grassy-leaved plants.

Eulalias (syn. Miscanthus) japonica and gracillima are two of the lightest forms. E. saccharifer is a giant grass growing 6ft. and over on occasion, and its rich green, boldly arched foliage is a note of distinction in itself. The lyme grass, too (Elymus glaucus), with its beautiful blue-grey masses of foliage, makes an effective colour note. Funkias enjoy the shadowed recesses higher up the bank. Pennisetum latifolium is a very decorative grass 5ft. or 6ft. high. Phormiums (New Zealand flax) are excellent plants used sparingly at definite points. Stenanthium robustum lights up the scene with large cream plumes of flower. Of arundos, the grassy-leaved A. conspicua, with plumes like pampas grass, is very beautiful

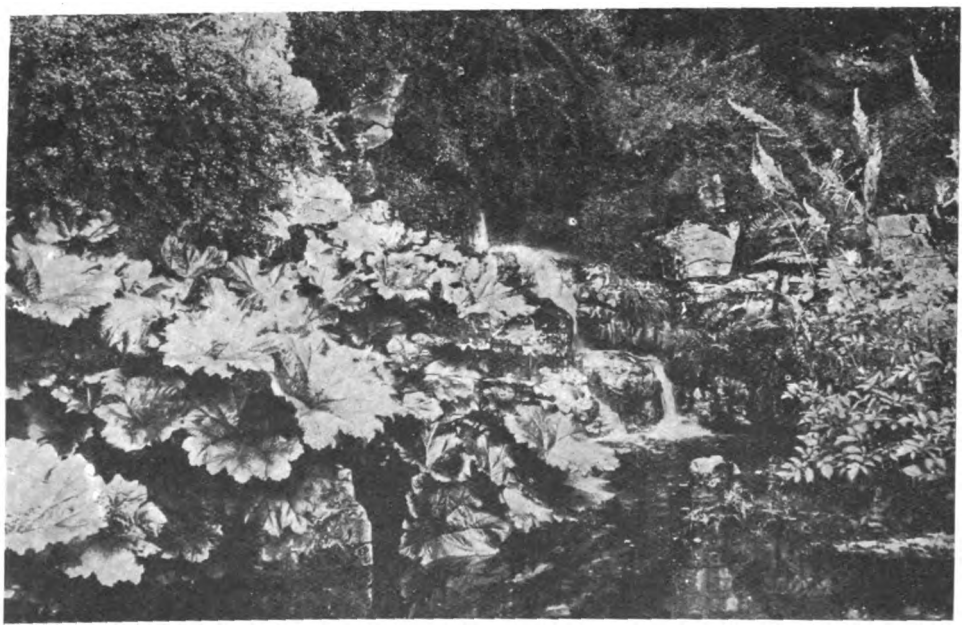
Digitized by Google

in the proper place; but the best of them is the giant Mediterranean reed, Arundo Donax, of which the best form is that known as macrophylla glauca, with delightful blue-grey leaves, that towers to a height of 8ft. or 10ft. and yet never loses its graceful outline.

But the water garden would be very poor indeed without its aquatics. Indeed, with me there is a feeling that all I have mentioned hitherto only exist to frame the picture of the water garden proper.

First there are the semi-aquatics. The sweet flag (Acorus Calamus) cool to look at and sweet when crushed in passing it. A variegated plant that, like those I have previously mentioned, loses nothing by its variegation is Acorus japonicus foliage variegatus. Glyceria aquatica will ramble along the banks and out into the shallow water and impart a lovely moonlight effect. The juncus, also, particularly the porcupine rush, J. zebrinus, add grace and beauty to the picture. The bog or buck bean (Menyanthes trifoliatus) will creep along the shallow margins. The blue-flowered water hyacinth Pontederia cordata, is a charming plant where it succeeds, but this is not everywhere. Then there are the arrowheads. (sagittarias), of which the Japanese form S. macrophylla is the best of the singles and S. variabilis fl. pl. the only good double, A true water-loving plant is Zizania latifolia (wild rice), which reaches a great height in a very short space of time. It will also reach a great distance from the spot in which it is planted unless kept in check.

The flowering rush (Butomus umbellatus) and the typhas (reed mace) are invaluable, and form excellent backgrounds for water lilies, as well as serving to shelter and protect them against wind or running water. T. latifolia is a plant for large areas only. T. stenophylla is a smaller-habited plant for the



SAXIFRAGA PELTATA BY THE STREAMSIDE.

water garden of moderate size, and the tiny reed mace, Typha minima, is a very pretty plant when bearing its little brown clubs. Plant it somewhere—just in the shallow water—if you can get it.

Of the true aquatics, that is, those plants that send their roots into the depths but whose leaves and flowers float on the surface. The most attractive are the native yellow flowered Villarsia nymphæoides, the yellow British water lily (Nuphar advena), the frog bit (Hydrocharis Morsus-ranæ) with its little brown floating leaves and yellow flowers, and the water hawthorn (Aponogeton distachyon) that flowers from the very early days of spring (I have seen it and smelt its delicious odour in March) until the last leaves have fallen from the surrounding trees in autumn.

I have long ago filled the space allotted to me by the Editor for this article, and I awaken to the fact that the real gems of the water garden, the nymphæas, or water lilies, must be crowded into a few brief lines. The whole water garden exists for them, for are they not its aristocracy, its fairy queens and princesses. I think it was Mirabeau who said that "God gave to Woman two-thirds of all beauty." This may be so, but I think that when the vials of beauty were being poured forth it must have been by the waterside, and some was spilt on the surface and became water lilies. No flowers can create quite the same emotion in the lover of all things beautiful as do the water lilies, and none possesses quite the exquisitely moulded forms or purity of colour that is found in them. Orange hearts in crimson goblets. Golden jewels nestling in snowy whiteness. All the rich glow of ruby and garnet, the soft pink of the rose, and the delicate flesh tints of an artist's dream are combined with a beauty of form and purity of outline that Nature in all her wonderful works has never excelled and rarely emulated. To describe even a reasonable number of the best is impossible. I will therefore content myself with naming some that should always be planted when opportunity arises.

For water 1½ft. to 2ft. in depth: Atropurpurea, crimson purple; Aurora, rose flushed yellow to salmon; Ellisiana, bright rosy red, deeper in centre, sometimes rather shy flowering; Froebeli, wine crimson; James Brydon, very deep rose, brown foliage, a marvel to flower; the Laydeckeri varieties, fulgens, purpurata and lilacea; odorata alba maxima and its pink form Exquisita, both vanilla scented; W. B. Shaw, bright rose pink; Wm. Falconer, deep crimson, perhaps the best of all deeply coloured for shallow water.

For deeper water, 4ft. being deep enough to plant any variety, although many will, once started, find their way into several feet more and succeed: we have Colossea, delicate shell pink, fragrant; Escarboucle, rich vermilion, anthers and all; Gladstoniana, the noblest white; marliacea carnea, free flowering shell pink: m. rosea, glorious flowers of soft rose; tuberosa, a solid white flower that reminds one of an exquisitely carved marble, very fragrant; t. Richardsoni, an improvement as to size on tuberosa, but scarcely so free flowering, I think. The limits of space and not of really first-class varieties must end the list here.

The water and bog garden possesses characteristics that are found in no other department. It has within its compass an atmosphere all its own. The subtle niceties of colour blending and colour grouping are hopelessly impossible here. You may try it, but it will beat you in the end. All growth is luxuriant, all its denizens are adventurers, and will ramble far from their own appointed place if you let them. Restraint is an unknown quantity, and in the garden regions the water garden usually hangs suspended between luxuriant civilisation and beautiful savagery. Leave it uncared for and it will soon make of itself a glorious, but, to the gardener, maddening wilderness. But however mad or wild it may become, it will be beautiful still. Colour, reflected from the bank above, dyes the water below to a crimson or golden wash. The splash of the vole or stirring wind sends ripples across the waters and gently sways the floating gems upon its surface. The music in the rustle of the reeds and rushes, the white floating clouds reflected in its depths, the sombre shadows under the giant leaves and the riot of colour on every hand: all these and many more are the pleasures of the water garden from early spring until late autumn.

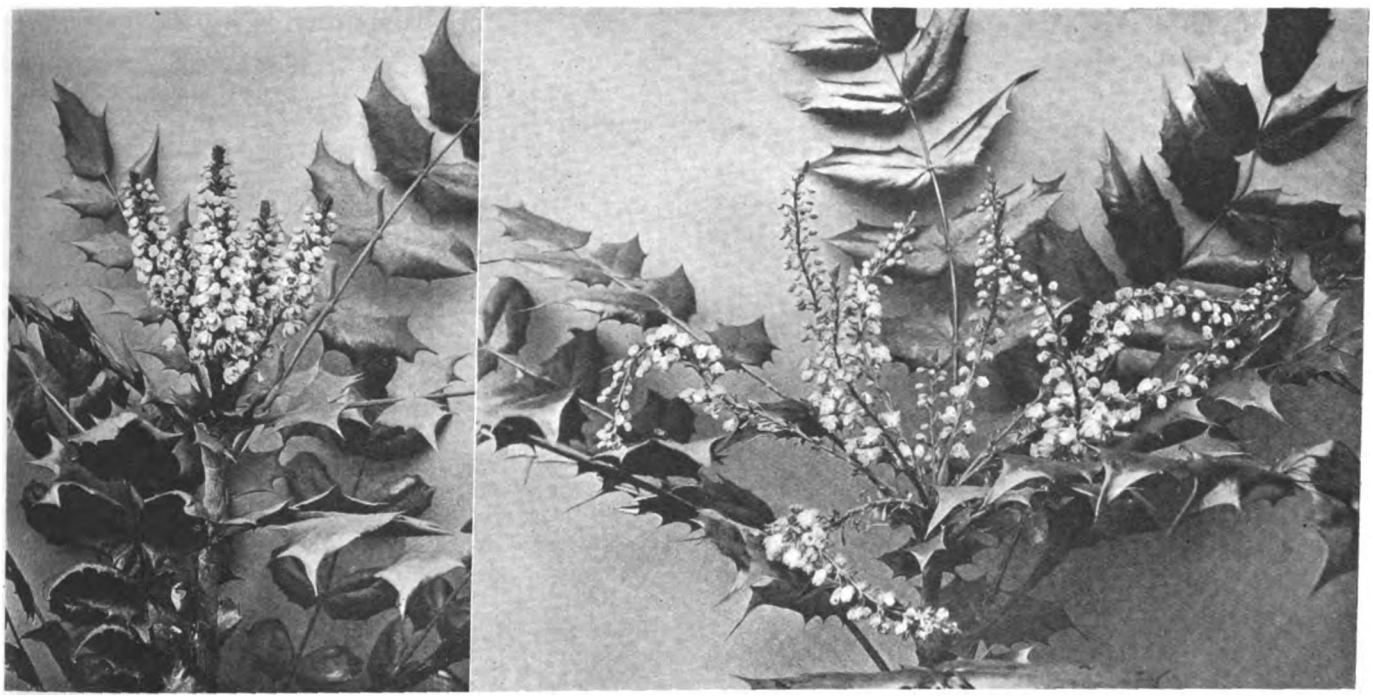
THE SO-CALLED MAHONIA JAPONICA

AS Mahonia—or, as it is more usually called, Berberis—japonica we frequently meet a fine evergreen shrub in the gardens of Great Britain as well as of the Continent. There are two or even more apparently distinct forms of it, of which one with larger, broader, more rounded and somewhat less spiny-toothed leaflets is known by the name var. Bealei. This one was introduced from China by Fortune in 1845, and Lindley described it in 1850, regarding it as identical with Berberis japonica Sprengel (1825) or Mahonia japonica De Candolle (1821). Fortune himself took the Chinese form for a distinct species (*Gardeners' Chronicle*, 1856, page 112), an opinion already held by Carrière, who described Mahonia Bealei in "Flore des Serres," X., page 166 (1854-55). Hooker, in following Carrière and Fortune, pictured the plant and what he called var. planifolia in the *Botanical Magazine* on Plates 4846, 4848 and 4852 (1855), from specimens sent to him from Messrs. Standish and Noble's nursery, where Fortune had sent his seed. Later, Fedde and most of the other authors have united the Chinese form with the Japanese one, calling the first M. japonica or var. Bealei.



MAHONIA BEALEI WITH ITS SOMEWHAT STIFF AND DENSELY ERECT INFLORESCENCE.

THE TRUE MAHONIA JAPONICA, CHARACTERISED BY LOOSE AND STRAGGLING FLOWER CLUSTERS

The last monograph of the genus mahonia, H. Takeda (in Notes, Royal Botanic Garden, Edinburgh, January, 1917) has been the first to explain that the true Japanese mahonia has nothing whatever to do with the Chinese forms cultivated in our gardens and called M. japonica. During my stay in the Arnold Arboretum from 1915 to 1919 I had the opportunity to study the material of the genus mahonia, and to see also the specimens investigated by Takeda. I have not yet published the results of my own investigations, but in this note I shall say what I know about Mahonia japonica, which even now is far from being sufficiently understood.

According to Ito (in Jour. Linn. Soc. Bot. XXII, 428, 1887) this plant does not occur spontaneously in Japan. Statements to this effect given by Miquel and Franchet et Savatier, or even Matsumura, are wrong. Keiske Keisuke Ito (translation of Matsumura, 1883) says: "This plant has never been found wild. It is said to have originally come from Ha ku san (mount) of the province of Kaga. But it is now everywhere cultivated in gardens." E. H. Wilson, who so carefully studied and collected the woody plants of Japan, did not observe a wild specimen, nor did he detect such a specimen in one of the Japanese herbaria. Takeda, too, states that the species has not yet been observed in a wild state, and that he "has seen no typical specimen of M. japonica collected outside Japan." He does not say anything as to the relationship of this species to others, and only under M. Fargesii he points out the resemblance of its leaves to those of japonica. In my opinion, M. Fargesii—or, at least, what I take for it—seems to be much nearer M. Bealei, while some facts seem to indicate a relationship of M. japonica to M. philippinensis Takeda. M. tikushiensis Hayata, too from Formosa, may be near to japonica, but, unfortunately, I know Hayata's species only from his description, and it is not yet mentioned by Takeda.

After all, I cannot decide the question of the origin of M. japonica. Most of the plants cultivated under this name are M. Bealei. Fedde, who apparently was not aware of the real differences between M. japonica and M. Bealei, did, in 1905, mention that Giraldi had collected several specimens of japonica in Shensi. I have seen no specimen of this collector giving proof of Fedde's statement. I presume that the plants Giraldi found belong to M. Fargesii. One is easily inclined to believe that M. japonica, like so many other plants, originally came to Japan from China. According to a Japanese garden book, a mahonia was introduced to Japan from China in 1684. Takeda, however, is not sure whether this was japonica or Fortunei, neither is he certain where the plant really came from. There is, in my opinion, a great probability that the real japonica did not come from China, but from Formosa, or even the Philippine Islands. It is or has been in cultivation in our gardens, but at present almost all the plants bearing this name belong to M. Bealei. I have, at least, hitherto never met with a flowering plant of the true japonica.

One of the flowering specimens here figured seems, however, to represent the Japanese species, and comparing it with the other picture of the true M. Bealei, we get a rather good idea of the different aspects of the two species. As Takeda first pointed out, the two plants "may show some resemblance in foliage under abnormal circumstances, yet an absolute distinction can always be seen in the inflorescences." The leaflets of M. Bealei usually are somewhat broader and upon the whole larger than those of M. japonica, which mostly possess one or two teeth more on the lower margin of the leaflet. The racemes of M. Bealei are, as a rule, rather stiff, erect, densely beset with flowers and with bracts not exceeding 4mm. in length, and the ovaries, according to my observations, contain

Digitized by Google

three to four ovules. In our picture the inflorescences are still young, and may later become somewhat looser; but in M. japonica the racemes are always rather slender, straggling or somewhat pendent, more loosely beset with flowers and with bracts that measure from 5mm. to 8mm., the ovaries of the few flowers I could investigate containing from four to six ovules. I should like to know whether there is a distinct difference in the colour and size and perhaps the fragrance of the flowers, and in the colour and size of the fruits of the two species. I should be grateful to anybody who could send me flowering or fruiting specimens of what seems to be the true M. japonica, or of forms of Bealei not quite agreeing with the one pictured.

CAMILLO SCHNEIDER.

GORSE

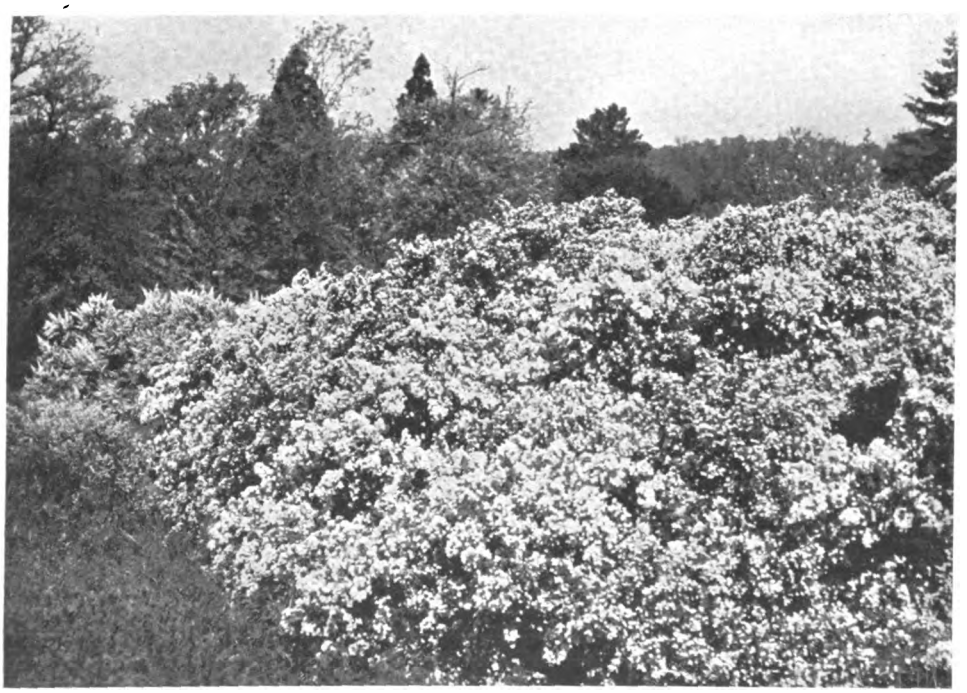
BY DR. R. LLOYD PRAEGER.

IN THE GARDEN THIS USEFUL GENUS OF SPRING SHRUBS IS OF EXTREME VALUE FOR PLANTING IN SITUATIONS UNSUITED FOR OTHER SHRUBS AND IN ADDITION IS MOST EFFECTIVE WHEN DRAPED WITH MASSES OF GOLDEN FLOWERS.

"WHEN the gorse is out of bloom kissing's out of fashion," runs the old saying; and if considered generically, not specifically, the botanical side of the analogy is fairly correct. For it takes more than one species of gorse to carry us the round of the seasons. The common gorse, Ulex europæus, puts forth tentative sprays of bloom (particularly in mild districts) from October onward; early spring sees it in full glory, and June is waning before the last blossom disappears. July presents difficulties, but by August the two remaining British species, U. Gallii and U. nanus, are beginning to flower, painting the heaths with gold in September and October, and still lingering till U. europæus begins again.

Ulex is a compact little genus of some twenty species, which evidently first arose in south-western Europe, for all the species save three or four are confined to Spain or Portugal (or both) and the others have a western range. The three kinds already mentioned as British are the most northern representatives, and of these U. europæus alone ventures north of Britain, being present in Denmark. I remember finding, with some astonishment, a few bushes on the East Frisian Islands (the discovery was appropriate, the occasion being my honeymoon and the date very near April 1st), but Professor Conwentz, to whom I showed specimens, scouted the idea of its being native there. It is reported as introduced into Bavaria also. U. Gallii resembles generally the last species, but is smaller and neater in all its parts, greener in colour, with flowers of a deeper gold. Its distribution in the British Isles shows its southern origin, for though it is abundant where it occurs, it haunts only the milder parts, mainly western England and Ireland. The third species, U. nanus, shows a more marked preference for a warm home, being confined to the south of England. It is the smallest of the three, a little prostrate shrub, with short spines and quite small flowers. None of the many Iberian species appears to be hardy, and one very seldom hears of any of them in British gardens. I have seen a few of them in Portugal, and it seems to be just as well for the peace of mind of English botanists that these gorses have not spread northward, as they appear to be among the most puzzling groups in the flora of the Peninsula.

An excessive and vindictive thorniness is characteristic of the whole genus. In the old days we were taught that thorns were a special provision of nature to prevent animals from eating the plants possessing them, and it was pointed out in support of this theory that thorny plants are especially characteristic of poor ground and desert places, where vegetable food is scarce. This was putting the cart before the horse. There can be no doubt that thorniness, representing as it does a restriction of growth, is an economical measure on the part of the plant, and a protection against undue loss of water, such as is likely to occur in deserts: the fact that it also protects against grazing beasts being quite by the way. The shrubby members of the pea family are to a great extent inhabitants of poor and dry ground, and in other groups besides Ulex we find thorny ends to the branches and thorns replacing leaves. The so-called needle whin of our moist heaths is an excellent example in the genus Genista, and G. hispanica, G. dalmatica and others look exactly like little gorses; Erinacea derives its name from its suggestion of a vegetable hedgehog; Ononis and other genera include thorny members in their family circle.



A GLORIOUS PATCH OF GOLDEN YELLOW PROVIDED BY THE DOUBLE GORSE.

But from the defiant groves of gorse what a wealth of glorious blossom bursts forth in spring! Where else shall we get such a blaze of colour, such an intoxicating warm fragrance! No wonder the story is told (whether true or not I do not know, nor does it matter) that Linnæus, coming from gorseless Sweden (or, as some sages sing, Dillenius, coming from gorseless Darmstadt), fell on his knees before so glorious a vision. And the story has a deep significance, for nowhere in the world, so far as my limited knowledge goes, is there anything that surpasses a field of gorse. Gorse and purple heather (the latter also a west European plant, and unknown, like the gorse, to the benighted inhabitants of central Europe)—these two, at their best, are without a peer. On Alpine slopes

Digitized by Google

we find more intense pigmentation, more varied tints: but for sheer overpowering mass of colour, commend me Ulex europæus and Erica cinerea.

A particularly pleasing trait of the gorse (and, indeed, of the heather too) is that it flourishes on ground which without it might often be rather barren and desolate.

All the gold in Ballytearim is what's
stickin' to the whin;
All the crows in Ballytearim has a way
of gettin' thin.

But while the heather succeeds in this by sheer economy of growth — thin twiggy stems and tiny leaves, aided possibly by the beneficent companionship of root-fungi—the gorse has a special private fund on which to draw, which it shares in common with other leguminosæ. I refer, of course, to the bacilli imprisoned in the peculiar root-tubercles. These bacilli, as is well known, possess the power (denied to the higher plant) of directly assimilating nitrogen—that most precious of plant-foods; the gorse is able to plunder this store, giving in exchange food and shelter; and so the two live happily together to their mutual advantage. So far as one can see, the bacilli might easily escape from their prison and live independently; but the gorse and its companions, in the absence of their tiny friends, might well go bankrupt and have to migrate to some new home where a richer soil would give a better margin of profit on the annual turnover.

GORSE LOOKS ITS BEST IN THOROUGHLY ROUGH AND NATURAL SURROUNDINGS.

Although their upland habitat might suggest an especial hardiness for the gorses, their European distribution warns us that in Britain they are near the limit of their climatic range. U. nanus, indeed, frankly keeps to southern England. As regards the other two, the absence of U. Gallii from Scotland (except parts of the south) and Denmark suggests that it is the more tender, and W. J. Bean states so in his admirable "Trees and Shrubs." At the same time, it occupies on the hills a well marked zone *above* that tenanted by U. europæus. The severe winter of 1916–17, which decimated the bird population about Dublin and killed most of the foxgloves, played havoc with U. europæus. In Wicklow about half of it was killed to the ground; but U. Gallii was no worse hit, and, indeed, so far as my observations went, it came through better than its ally. The testimony on this question of other observers would be welcome.

It is just as well for the gorse, and all the worse for the farmers, that its spines are so efficient a defence against grazing animals, for when these are rendered impotent it is readily eaten, and makes an excellent and probably nutritive fodder. In some parts of England rough mills for bruising gorse are (or were) used. In the North of Ireland one of the many duties of the farm labourer used to be "knockin' whins"; they were beaten with a large wooden mallet in a wooden trough, and were then given to cattle. Why should not var. strictus (to be referred to later), which is soft enough to be eaten without pounding, be used as a fodder? It grows quickly, and would rejoice on ground too poor and thin for any other crop.

The leaves of the gorse are interesting both on account of their curious modification and because they do not seem to have made up their mind whether to take the form of a simple leaf (as in a few species of cytisus, a close ally) or whether to retain the trifoliolate leaf which is characteristic of so many of their relations, and which is presumably the ancestral form. This point is best studied in seedlings, for the young gorse begins its career with a number of small but well developed simple or compound leaves, before these become reduced to the mere spines or tiny scales which characterise the adult. U. europæus usually bears several pairs of trifoliolate leaves following the cotyledons, then a few flat simple leaves, and then the characteristic round spine-leaves. U. Gallii has usually one pair of compound leaves, followed by several pairs of flat simple leaves. But in both species the leaves of the young plant may be all simple or all compound, or simple and compound may be mixed irregularly. One is justified in assuming that these plants are losing their primitive (trifoliolate) type of foliage, and adopting instead small hairy lanceolate leaves like those of Genista sagittalis.

It is difficult in the garden to get any of the gorses to look really happy, for they are accustomed to thoroughly rough conditions—sun, exposure and a poor soil. In cultivation they soon get leggy, and end by looking like scarecrows and dying untimely. It is necessary to give them the poorest, driest, windiest place that one can find. Their garden value, indeed, consists largely in their capacity for furnishing unpromising ground of this kind, where few things would flourish. Much the best plant for the purpose is U. europæus flore pleno, the double gorse, which makes a beautiful display in spring if only it can be kept compact. An interesting though not showy plant is the Ulex strictus of Mackay, which also belongs to U. europæus. It is a "juvenile form," a variety which, like Peter Pan, has never grown up. It has an erect habit, the prickles are very short and so soft that one can grasp a branch in the hand. It flowers very sparingly at the tips of the branches, and is reported to revert—at least in part—to typical europæus if sown; but I do not know whether this statement has been made with reference to the results of self-pollination, or whether there may have been a crossing with ordinary europæus. The specimens seen in British gardens are presumably all derived from cuttings of the single plant which was found at Mountstewart in County Down about 1820 by a local nurseryman, Mr. Murray, from whom John White, the author of "The Grasses of Ireland," obtained it and brought it to Dublin, where J. T. Mackay saw it and described it (though very inadequately).

HERBACEOUS PHLOXES

OF ALL OUR BORDER FLOWERS THERE IS NONE WHICH PRESENTS US WITH SUCH A WEALTH AND VARIETY OF COLOUR AS THE PHLOX.

WITHIN the last twenty years great progress has been made with herbaceous phloxes. Whereas the herbaceous phloxes of our boyhood were ungracefully tall, poorly coloured, had thin spikes and small flowers, the modern varieties are of stout, mostly dwarf stature, brightly and most differently coloured and have individual flowers as much as 2ins. across, grouped on large, stately, pyramidal trusses.

The chief raisers to whom we are indebted for these changes are Lemoine of Nancy, France, who has been working on phloxes ever since 1859, when the first novelties of the firm were sent out, also Pfitzer, Goos und Koenemann, in Germany, Ruys in Holland, and, in England, several specialists too well known to need mention here.

The herbaceous phlox has now become a first-rate border plant, owing to these improvements and to the fact that different ways of cultivation enable one to have it in flower all the summer through, from July onwards till September and October. Its range of colour is truly marvellous, extending from salmon and red to white, blue and violet, all exceedingly brilliant shades, linked up by all possible intermediaries — except that yellow does not exist. Easy culture and great facility of propagation also contribute to its great popularity. As a cut flower, although little has been said so far on the subject, it is also much to be recommended, not perhaps for the trade, but for private houses where the stems can be cut when required and put straight into water. It then keeps bright for several days and exhales a very sweet and gently penetrating perfume, most pleasant in the house.

HERBACEOUS PHLOXES ARE ALWAYS USEFUL IN THE BORDER.

Few other hardy plants, with as little care and trouble, succeed so well in the border or are so exceedingly brilliant as the phlox. With it, cultivation is reduced to the strictest minimum; every year, a simple liberal dressing of some light and highly fertilising material should be given in the spring at the time when the usual forking of the upper soil is done. No staking or very little, is required. The plant ranks also among the truest of perennials and is sure to come up year after year. A point on which it is nevertheless useful to lay stress is always to give the herbaceous phlox a rich, porous and warm ground and as open a situation as possible. In poor soils and too shaded places it gives thin spikes and small flowers and is rather susceptible to summer drought. A good way to maintain strong and healthy plantations is to establish young propagations as often as possible, and never twice on the same spot, or at least after a long interval. This is the secret of many successful growers. The plant being a gross feeder can thus grow vigorously and so resist the diseases which sometimes affect old and poorly grown plantations. In the herbaceous border, this desirable continuous shifting and propagation is not possible, but very liberal annual dressings act to a large extent in the same way. At all times and under all conditions, the plant benefits greatly from frequent stirring of the surface soil with the Dutch hoe or some other such implement, a practice which, by the way, saves much labour in watering during the hot season; as, indeed, it will do in the case of every plant.

The herbaceous phloxes present a great diversity as regards their heights. Some varieties, like Josephine Gerbeaux, will attain a height of 5ft., and some others, such as Tapis Blanc, rarely exceed 1ft. or 1ft. 6ins. The more useful for the border are probably those of about 3ft.—particularly as it is mainly in that height that the finest varieties are to be found. A good plan in establishing borders is to take advantage of this difference of heights by having phlox disseminated throughout the whole of the beds, in front, in the middle and at the back. As regards colour, a certain number of varieties, mainly in the scarlet and fiery shades, are sometimes somewhat spoiled by the sun. In that case, it is best to plant in partial shade; which is an easy matter, as phloxes look particularly well when forming a foreground in front of shrubs, walls, tall herbaceous plants, or under thin trees, etc. In all cases, only one variety must be planted at a time, since a mixture of varieties never gives the same brilliant display as distinct, showy patches of one colour.

To give a selection in the numerous varieties of phloxes now in existence is not an easy matter, but here are a few:

ÆGIR.—A fiery red, fine colouring, unaffected by sun.

ANTONIN MERCIE.—Dark lilac with white centre: large flowers, very free and distinct.

BARON VAN DEDEM.—A beautiful shade, orange scarlet, large pips. Has superseded the older Coquelicot.

ELIZABETH CAMPBELL.—Delightful light salmon, changing to pink, large flower. Ought to be in every collection.

EUROPE. — Snow white flowers of fine substance, with central rosy ring. Large compact trusses.

EVANGELINE.—Very rich salmon pink. A showy plant.

FRAU ANTON BUCHNER.—Probably the finest white in existence. Large trusses and flowers. Habit stiff and dwarf.

GENERAL VAN HEUTSZ.—A dazzling shade of salmon red with distinct white zone at the centre. A most effective variety.

G. A. STROHLEIN.—Loose branching trusses. Orange-scarlet with bright carmine eye. A nice shade.

HOMELAND.—A comparatively new variety with large trusses of brilliant orange, and pips distinctly red.

LE MAHDI.—One of the best of Lemoine's varieties and of magnificent colouring. Rich violet blue. A first-rate plant.

MARECHAL FOCH.—Probably the best crimson in existence. Large flowers. Eye darker.

MARIE JACOB.—Very large truss, pale lilac with white eye. Pretty and distinct.

MIA RUYS.—A beautiful white, dwarf, very large pips.

MRS. MILLY VON HOBOKEN.—Enormous trusses of salmon pink colouring. Fine plant.

MONS. KIND.—Bright orange-red, shaded copper. Good habit.

MRS. SCHOLTEN.—Large pyramidal trusses. Fine dark salmon pink.

Digitized by Google

NEWBIRD.—Pleasing variety of recent years. Rich amaranth crimson. Large pips and spikes.

NICHOLAS FLAMEL.—Brilliant scarlet red with purple eye. Very large pips.

PANTHEON.—A comparatively old variety still popular through its beautiful and distinct rosy salmon colouring and good habit.

RIVERTON JEWEL.—Well shaped trusses of large flowers, mauve pink with brilliant carmine eye.

RYNSTROON.—One of the most beautiful phloxes. Enormous trusses on rather dwarf stems. Lovely soft rose colouring.

SEGRID ARNOLDSON.—A fine deep crimson of bold aspect and good constitution.

SELMA.—Of Dutch origin. One of the best of its colouring. Lovely bright pink with bright cherry red centre. A good doer.

THOR.—Rich salmon, suffused white and carmine eye.

Phloxes sometimes suffer from a pest, common among daffodils and other bulbs, called "eelworm" or "Tylenchus devastatrix." It is a small nematode about one-sixteenth of an inch long that attacks the plant on ground level and rapidly kills the upper part of it. The only remedy known is to cut the stems as soon as they show signs of ill health just below the ground level and to burn them at once, or better still to burn the whole of the plant. Phloxes are also attacked by a bacterial disease caused by the "Bacillus caulivorus," which affects the plant at the base of the stems and soon kills it. Plants that have been frequently transplanted and propagated, and given rich soils, are far less susceptible to these diseases and pests. In early spring the leaves of the phlox are often attacked by a fungus which gives the leaves a very crumpled appearance, but this can to a certain extent be kept in hand by the use of an appropriate fungicide. C. L.

SOIL ACIDITY AND PLANT GROWTH

BY T. EDEN (*Rothamsted Experimental Station*).

THE responsiveness of plant life to differences in the nutrient properties of the soil is everywhere manifested, and the importance of ensuring that sufficient of the various plant foods are present in the ground is realised; the highly important process of manuring is the natural consequence of such knowledge. It is not, however, so widely recognised what an influence "soil reaction"—and by that is meant the degree of acidity or alkalinity of the soil—has on the vigour, fruitfulness, and even the distribution of plant life.

Soil acidity or sourness is always associated with deficiency in lime, and in England at any rate the converse is usually true, that soil alkalinity is due to excess of lime or chalk, unless the soil reaction has been made alkaline artificially by the use of alkaline fertilisers. In America and Egypt there are vast tracts of land where excess of common salt has led eventually to a state of pronounced soil alkalinity. So far as this country is concerned soil acidity is liable to develop on all types of land where lime or chalk is deficient, though the presence of other basic mineral substances may to some extent remedy this defect. Water-logged soils rich in humus material under conditions of bad aeration and scanty lime and mineral content produce the so-called humic acids, and are characteristically acid. No other soils attain to such a high degree of acidity under normal conditions; moorland soil is a typical example of this class. Where lime is available, soils of a similar nature, waterlogged to the same degree, have their acidity neutralised, and owing to this and other changes consequent on their non-acidity, become productive fen soils. At the other extreme of soil moisture and humus content are the light sandy soils, which rapidly turn acid through sheer exhaustion of their lime supply by leaching out, *i.e.*, loss by drainage of substances dissolved out of the soil by the moisture it contains. It is estimated that under varying conditions of soil and rainfall from three hundredweights to half a ton of lime per annum is lost from an acre of cultivated land. Between the light sand and the peat there lie soils of varying mineral, lime, humus content and leaching propensity in which the phenomenon of acidity is present to a corresponding degree. There is, in the face of such conditions as those just described, little wonder that large areas of land untouched agriculturally or horticulturally are in a very acid state, and that to the farmer and the gardener the problem of counteracting the ever-increasing tendency to acidity is of the utmost importance.

The existence of soil acidity can often be surmised from the presence of specific weeds and natural herbage; more will be said on this point later. A chemical test is the surest means of settling the question, and a very simple and effective one is described by Professor Comber. In a test tube or small bottle place about a teaspoonful of dry soil and add a solution made by dissolving a few crystals of potassium sulphocyanide in alcohol. (This should be procurable at any good pharmacy.) The test is dependent on a colour change, so that methylated spirit is not satisfactory. When the soil is well covered, shake thoroughly and allow to stand until all turbidity has disappeared. The solution will remain colourless or only slightly tinged with brown if the soil is not acid, while a deep red colour of varying intensity will denote corresponding degrees of acidity.

The effect of soil acidity on the plant is best demonstrated on such highly acid soils as moors and heaths where no attempt has been made to preserve a balance of lime in the soil. Broadly speaking, plants fall into three groups with regard to their behaviour to conditions of soil reaction. These are:

(1) Plants which will tolerate only a small range in soil reaction and which flourish best in a neutral or slightly alkaline soil.

(2) Plants which in a similar fashion tolerate only a small range of soil reaction and whose optimum growth conditions lie in the region of slight acidity.

(3) Plants which will tolerate a relatively big range of soil reaction but which undoubtedly do best in well conditioned soil.

The first group contains many of the cultivated grasses, grain crops and leguminous plants, particularly lucerne and sainfoin. If the limit of soil acidity which these can endure is passed they fail. Clover in an acid field will be patchy and timothy grass grown with other species in a meadow will succumb to the competition for the necessities of life which takes place between it and hardier species.

The second group is small and specialised, and the heath family are among the most important members.

The last group comes between the other two in the matter of numbers, and in it are found those plants, like sheep's sorrel and spurrey, which are looked upon as indicator plants for soil acidity. As has been mentioned, by themselves they would thrive in a sweet soil, but they can more than hold their own against the less tolerant species in conditions of acidity. Finally, they cover a large portion of the ground and become the dominant species, though under conditions more favourable to their competitors they would themselves suffer almost complete extinction. Because of this competition and difference in tolerance, soils of different types with regard to acidity develop different types of flora if untouched by man. A few examples may be of interest. Marshy land where acidity is not prevalent will grow the giant reed, the bog myrtle and the bog bean, while in just the opposite circumstances one may expect the sphagnum moss, cotton grass and cranberry. A typical limestone woodland will generally contain a considerable number of ash trees; its grasses will be broad-leaved, its damp places sprinkled with forget-me-nots; while on its edge a number of the wild orchids may grow. A wood on an acid soil will have oak and birch overhead, hair-grass and sheep's fescue under foot, many kinds of sedges and rushes in damp hollows and on its outskirts a heather colony.

The soil of the garden, however, is seldom so extreme in the matter of acidity or alkalinity as virgin land, nor does the competitive factor enter to any great extent except in lawns. Nevertheless, the effects of varying soil reaction may be clearly traced in a number of instances. The following examples are chosen so as to illustrate the several ways in which the acidity or alkalinity may affect the plant. Changes in reaction may upset the balance of the different food constituents in the soil nutrient solution, with bad effects on the health of the plant Roots, too, are liable to injury by extreme conditions. It is in these two ways that, very probably, the majority of plants are influenced. But, as with wild plants, garden plants vary in their tolerance, so that while strawberries and bilberries thrive on acid soils, and deciduous fruit trees prefer slightly acid conditions, the gooseberry is easily injured by such treatment. The chestnut, azalea and blackberry, according to experiments conducted in America, are actually injured by liming.

A second way in which soil reaction may affect the plant is by cutting off from it entirely some necessary element of plant food. Two cases of this phenomenon have recently been mentioned in the correspondence columns of THE GARDEN under the head of change of colour in hydrangeas and chlorosis of fruit trees (February 7th, 1925). As explained, these effects are due to lack of iron, which is made non-available to the plant in the presence of excess of lime. To what has already been said two details may be added. The first is that the change from blue to pink flowers in hydrangeas commences while the soil reaction is still slightly acid; and, secondly, the effect produced by chalk which was quoted as safe, and that produced by lime which was cited as unsafe, is

Digitized by Google

really only a question of degree. The former is much less effective than the latter in making the soil alkaline, so that while chalk will only in most cases alter the soil reaction sufficiently to cause depletion of iron to that degree which promotes change in colour, lime may push the reaction farther and cut it off altogether, bringing about severe chlorosis and death.

It is well known that certain families of plants have micro-organisms living in their root cells, and that each makes an important contribution to the means of livelihood of the other. It is of the essence of this phenomenon of symbiosis (=living together) that the good of the one is the good of the other. Consequently, another method by which soil reaction may affect a species is by rendering the co-partnership impossible. Already it has been pointed out that it is sometimes soil acidity and at other times alkalinity which produces harmful effects, and in symbiosis the same variety of behaviour is encountered. The roots of leguminous plants have small nodules on them containing bacteria which actively extract nitrogen from the air in the soil and lock it up in the cell tissue. These bacteria as a general rule require a non-acid soil. A comparison of the roots of beans or peas grown under well limed and poorly limed conditions will immediately show the harmful effect of the latter on the number and size of these nodules. A classical example of this preference for well limed soil occurs on the park grass plots at Rothamsted. Many of these plots have received the same manurial treatment year after year since 1856, and some, in consequence of the continuous use of sulphate of ammonia in abnormal doses, have been made very acid by leaching out of lime; from these plots legumes have disappeared entirely. In this connection it may be mentioned that the other largely used nitrogenous fertiliser, nitrate of soda, has the reverse effect on soil reaction. Ericaceous plants, like the rhododendron, also have a micro-organism, the fungus mycorrhiza, in their roots, but in order that this may survive, a slightly acid reaction is necessary. The work of Dr. Rayner on the common heather has made it clear that the fungus cannot live in the roots if lime is present in the soil. In such cases the heather never becomes a mature plant. It is highly probable that this, too, is a case of preferential soil reaction. Heather is always associated with acid soils, and when, as in certain parts of Derbyshire, it is found on limestone, further investigation invariably shows that thorough leaching has exhausted the surface soil of lime. The rhododendron is a parallel example, and the use of peat, with its acid properties, for bedding round the roots has therefore sound justification.

There remains one very important way in which soil reaction can influence the plant, that of changing its susceptibility to parasitic disease. Anything which lowers the vitality of the plant will aid parasitic attack, especially from fungi, and in some cases soil reaction will directly affect the fungus. The most striking example is afforded by finger-and-toe disease in turnips and club root of cabbages. This disease is definitely associated with soil acidity, and if the land affected is limed and cropped with some non-cruciferous crop for a year or two the fungus will be unable to withstand the change and will be stamped out. The other side of the picture is furnished by the potato, which in some soils is subject to a fungus attack causing common potato scab. Of a number of cases brought to the notice of Rothamsted during the past two years most could be directly traced to excessive use of lime. In this instance the potato can withstand without injury a degree of acidity which is fatal to the parasite. In America the use of sulpbur to render the soil more acid has met with remarkable experimental success on the very few types of soil that have been tried.

It will be evident from these remarks that generalisation with regard to soil acidity is difficult, but in the long run acute acidity will kill practically any plant. There is, too, a real danger of the wastefulness of acid soils being overlooked in gardening. Where something is known of the preference of the crop in question, allowance should be made in the matter of rotation and liming. In any case of doubt a simple trial with lime and without will give the observant gardener the information he seeks.

TUBEROUS BEGONIAS FOR BEDDING PURPOSES

BEGONIAS FORM ONE OF THE MOST ORNAMENTAL GROUPS IN OUR LIST OF CULTIVATED PLANTS. WITH THE ARRIVAL OF NEW SPECIES AND THE BIRTH OF NUMEROUS VARIETIES AND FORMS, THEY PRESENT A WIDE CHOICE TO THE CULTIVATOR. SOME MAY BE GROWN PRIMARILY FOR THEIR FOLIAGE, OTHERS FOR THEIR SHOWY BLOOMS. MANY PROVE EXCELLENT SUBJECTS FOR THE CONSERVATORY AND GREENHOUSE, WHILE OTHERS, AGAIN, ARE MORE SUITABLE AS BEDDING PLANTS.

BEGONIAS in all shades of yellow, apricot, orange, pink and crimson, either blended together or massed in one colour, form one of the most beautiful and effective of all bedding plants. Both tuberous and fibrous-rooted begonias are used for bedding purposes, but the former are more popular. Tuberous begonias are exceedingly showy bedding plants, are easily raised, can be obtained in a wide range of colour, and flower for a considerable period. They are particularly useful in that, even in a wet summer, they flourish and bloom well.

During the month of March tuberous begonias should be started if the best results are to be obtained. Where a greenhouse is not available, a hot-bed will answer the purpose in a satisfactory manner. Use shallow boxes filled with leaf-mould or a rich, light soil, and press the tubers lightly into the soil—they should not be covered. There will be an interval after the tubers are placed in the boxes before they start to grow, and during this interval very little water need be given so long as they are kept moist. When the shoots have reached a height of about ½in., gradual hardening off should be commenced. A cold frame is best for this purpose, but if there is danger of frosts the plants require to be protected by covering the frames at night with mats.

Early in June the plants will be ready to go out of doors, and should be planted in their permanent positions, between 6ins. and 12ins. apart, the distance depending upon the size of the plants.

It is unnecessary to plant in a sunny position, as begonias thrive very well although in partial shade. Until autumn frosts begin they will continue in flower, showing their first blooms as early as the middle of July. They need a great deal of moisture during the flowering period.

After they have lost their beauty they should be taken up carefully and dried. They may be safely kept through the winter if they are stored in boxes of dried soil in a frost-proof shed until the following spring.

The soil in the boxes in which the tubers are stored should be kept dry, but not bone dry, or the tubers may begin to decay. A little water given very occasionally will prevent this, but it is easier to overdo the watering when the tubers are at rest than to give too little. Exercise the greatest care therefore when giving water at this period.

Although they may be successfully grown from seeds, the seedlings have little value as bedding plants during the first season, but on the other hand the colours are often exceptionally good.

Both single and double flowered varieties are available, and both are attractive, with their gay colouring; but the single ones are to be preferred for use in beds. The reason for this is that the double varieties expand less freely.

There is a fairly simple method of propagating begonias which was largely favoured when named varieties were more popular. As this method is useful for increasing plants of any particular type and colouring, it is worth describing. Half bury the tubers in sandy soil in a box which should be placed in a warm house. When the eyes push out from the crown, lift the tubers and remove all soil. These tubers should then be cut through cleanly, and, in order to give the cut pieces a better chance, take care that there are two eyes on each piece of corm. Only large bulbs which throw up three or four shoots can be safely treated in this manner. If cutting is carefully done the plants will continue to grow on without a check. They must, however be placed in a warm house for some time after dividing.

To be successful with begonias they must be given thoroughly good treatment, but the results then obtained amply repay the labour expended.

Among tuberous-rooted varieties may be mentioned Snowdrift, which has double white flowers; General Allenby, with its crimson scarlet double flowers; Mrs. W. Cuthbertson, the flowers of which are frilled and are lilac-rose in colour, these are also double; and Queen of the Belgians with its large double flowers of cerise-pink colouring. J. W. MORTON.

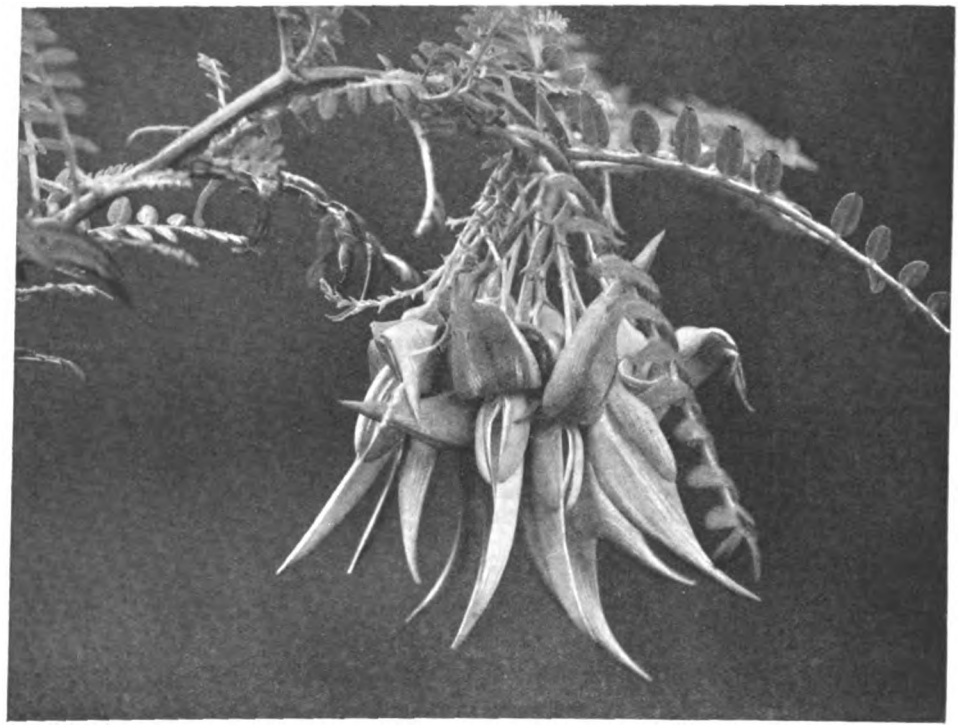
CONSERVATORY AND GREENHOUSE

ACHIMENES in many beautiful varieties are very useful for greenhouse decoration during the summer and autumn months, and it is surprising that they are not more generally used for this purpose. They can be raised from seed, which should be sown during February in pots or pans of light sandy soil, placing the seed-pans in a warm moist house with a temperature of 60° to 65° Fahr. The young seedlings should be pricked off into well drained pans of light rich soil; they should be kept shaded from too bright sunshine, and when they are about 2ins. in height may be placed several inches apart in their flowering pots or pans. As they are shallow-rooting plants, pans are well suited for their successful cultivation. Excellent examples can also be grown in 5in. pots. They should be grown on without any check in a temperature of about 60° until they are nearly in flower, when they should be accustomed to cooler conditions before they are removed to the greenhouse. If well grown they should flower towards the end of summer. The named varieties are grown from rhizomes which have been stored in dry sand over the winter. They should be started some time during February by laying out to start in leaf-soil and sand in shallow seed boxes, in a temperature of 60° to 65° Fahr., taking care not to over-water them until they have made some growth; When this is some 2ins. in length they should be placed in their flowering pots or pans, spacing them out from 3ins. to 5ins. apart, the greater distance for the stronger-growing varieties, such as A. longiflora and its varieties. Their subsequent cultivation is on the same lines as that advised for the seedlings. Free drainage and a light rich compost are essential for success. Achimenes, especially the more slender-growing varieties, are excellent for filling hanging baskets; indeed, A. coccinea always does better in baskets than pots. They are very subject to attacks of white fly and begonia mite; the former must be kept in check by fumigating with hydrocyanic acid gas or some other approved remedy; the begonia mite can be prevented by the occasional use of the sulphur vaporiser.

CLIANTHUS DAMPIERI (Glory Pea of Australia).—This plant has always, and not without reason, been regarded as difficult to cultivate successfully. Plants raised from seed and grown on their own roots are very uncertain, but by grafting them on seedling stocks of Colutea arborescens (bladder senna) one has a much better chance of growing this plant successfully. As grafting is done when both plants are in the seedling stage, it is a very delicate operation and requires considerable skill on the part of the cultivator. The seeds of the colutea should be sown about ten days before the clianthus, placing them in a warm house with a temperature of about 60° Fahr., the clianthus being sown in the same temperature. When fit to handle the coluteas should be pricked off singly into thumb pots, taking care to leave the swollen hypocotyl above the soil. The operation consists in cutting out the leading growth or young stem from between the leaves of cotyledons; the swollen portion should then be split downwards with a sharp razor, the tiny seedling clianthus should then be cut off and trimmed to a wedge shape and inserted in the slit made in the stock, afterwards binding it together with a piece of soft bass or thread. If the worked plants are placed in a close warm case they should quickly unite, when they should be removed from the case and stood on the stage well up to the roof glass, keeping them shaded for a few days.

As they require it they should be potted on into well drained pots, taking care to disturb the roots as little as possible. As they increase in size they should be gradually accustomed to an ordinary greenhouse temperature. They may be grown on into 8in. or 9in. pots, training the shoots up to wires, and are also excellent for filling large hanging baskets. The writer has obtained excellent results by planting them out on a well drained and raised bed in a greenhouse. This plant is very subject to attacks of red spider; this must be carefully guarded against, as, once affected, it is very difficult to get rid of them, as the leaves are closely covered with fine silky hairs, which give the whole plant a silvery grey appearance.

CLIANTHUS PUNICEUS, which is a native of New Zealand, is a very different looking plant from C. Dampieri, and, unlike that plant, its successful cultivation presents no difficulty. In the west it grows freely and makes a large plant outdoors against a warm wall. It is easily raised from seed or cuttings, the latter rooting readily in a close case with slight bottom heat. Good specimens may be grown in 8in. or 10in. pots, but this plant is only seen at its best when it can be planted out in a cool house and trained up a back wall or pillar. This species is liable to attacks of red spider, but they should be easily prevented by a vigorous use of the syringe.



A FINE SPRAY OF CLIANTHUS PUNICEUS FROM NEW ZEALAND.

LATHYRUS PUBESCENS. — This beautiful climbing plant is a native of Chili and is an ideal plant for the cool greenhouse. In the south and west it is hardy when planted against a warm wall. It is surprising that this beautiful plant is not more generally grown, as its successful cultivation presents no difficulty, and its sweet-scented, dark lavender-blue flowers are very attractive and are useful for a supply of cut flowers. To have it at its best it should be planted out in a well drained bed or border, and the shoots trained up a back wall, or to wires under the roof glass; a light position is essential, and the writer has grown it well planted out on a raised bed in a carnation house. The seed should be sown in a temperature of 50° to 60° Fahr., in which they quickly germinate. The young plants should be grown on in pots until they are about a foot high, when they may be planted out in their flowering positions. They grow quite well in any good potting compost, and are at their best the second and third year from seed sowing.

LATHYRUS SPLENDENS is a native of California, and is a very beautiful plant with dark red flowers. In the west it succeeds outdoors when planted against a warm wall; in other parts of the country it requires the shelter of a cool greenhouse. This fine plant is best raised from seed, but can also be propagated by means of cuttings, which root in a close case in a cool house. The seeds germinate readily in slight heat, and, like L. pubescens, the young plants should be grown on in pots until they are large enough to plant out in their flowering quarters. I have found it succeed best planted out on a raised bed and the slender shoots trained to wires under the roof glass; or it may be planted at the foot of—and trained up—a sunny back wall; in the latter position it is seen to better advantage. This plant is by no means so easy to do well as L. pubescens, and at present is scarce in cultivation; this is unfortunate, as it should be easy to procure seeds from its native country.

CAMELLIAS, at one time great favourites, have been out of favour for many years, and yet there are few more handsome plants for planting out in a large conservatory, and they have the advantage of being perfectly hardy in an unheated house. In recent years there has been a brisk demand for them, especially for the single forms, of which there are now many beautiful varieties, such as C. magnolæfolia Lady Clare, Kimberley, White Swan and C. japonica grandiflora (Mrs. Sander), to mention only a few. C. rosæflora is very charming, with small double rose coloured flowers and, of course, the best of them all, where room can be found for it, is C. reticulata, with its large semi-double rose-red flowers. J. C.

SIMPLE GARDENING

FIGS.

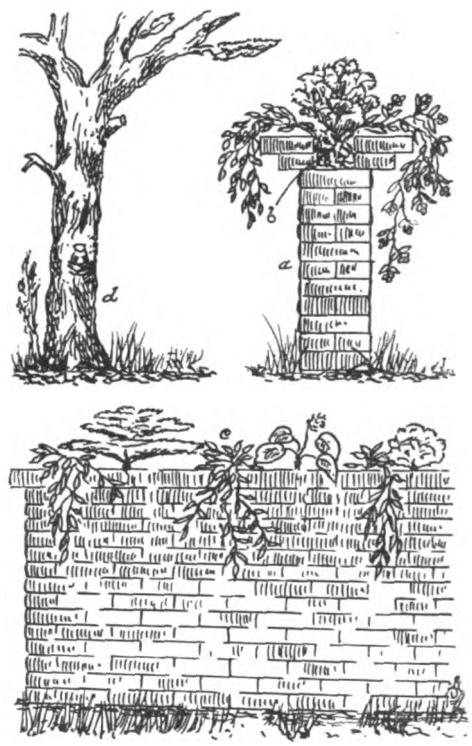
AN old fig tree in an old garden seems to be quite a part of it. Some old specimens bear well, others do not. I have grown, with equal success, trees over one hundred years old and quite young specimens because I was able to apply the right treatment. In the southern counties the trees, on good walls, rarely require any protection in the winter. In the northern counties it is advisable. Old specimens not fruiting satisfactorily may be overcrowded with long-jointed, unripe branches every year, or the roots may be rambling in a rich soil intended for vegetables near by. The inexperienced cultivator, wishing to grow figs outside, should select the variety Brown Turkey, because it is hardy, fruitful and of high quality. The next consideration should be the site for the tree. Of course, a high wall facing south is the best one. One sees old specimens with their branches trained on walls facing south and west respectively, the tree being planted in the angle of the walls. The rooting space must be restricted. Six feet by 3ft. 6ins. and 3oins. deep will answer as a border for a tree for many years. The drainage should be good, the turfy loam too; manure is not required, but some old mortar rubble is. The new bed must be made very firm while the soil is rather dry. Then ordinary watering and a surface dressing will do for the summer treatment for the roots. The branches should be trained 18ins. apart, very sappy bits should be pinched out altogether, also the ends off the shoots when the latter bear five or six new leaves and embryo fruits. Do not cut fig branches.

FIBROUS ROOTED BEGONIAS FOR THE GREENHOUSE.

In recent years the fibrous-rooted begonias have been much improved; the strains sent out by our nursery and seed firms being pure and reliable. Those persons who are not able to procure, or grow, the tuberous begonias or who prefer the fibrous ones, should not hesitate to grow a number of plants in pots. It is rather late in the season now to sow seeds, so the best plan is to make a selection of the tiny seedlings already in the pans, perhaps, for bedding out purposes, and, in due course, pot them separately. There are several fine colours on the market, I name three only: Fairy Queen, in pink and white respectively, and Coral Pink. There are crimson shades, but these are not as attractive in a greenhouse as the pinks, and a good white enhances their beauty besides being most useful for staging between pinks and other colours in the greenhouse that would not harmonise. Not only during the summer, but the early autumn months, too, good strains of the fibrous-rooted begonias continue to flower. Where the turfy loam is of a heavy nature a greater proportion of rotted leaf soil should be used in the compost. In the case of sandy loams less leaf-soil should be mixed with it. Re-pot the tiny plants as they need more rooting space, till they occupy 5in. and 6in. pots. These are quite large enough. Give the plants frame treatment during the month of June, then transfer them to the greenhouse. Do not use strong manures at any stage. Stimulants should be given in weak doses and seldom. Stopping is not necessary.

PLANT-GROWING ON OLD WALLS.

The accompanying sketches show how rock plants are grown on an old wall in a Hampshire garden. It is now nearly forty years since I first saw this particular wall; the plants had, then, been recently planted. I saw the wall a few months ago and many of the original plants, some of the latter being more than 2ft. across. The flowering subjects blossom splendidly. The sketches show how the wall is prepared for the plants; the wall itself is partly under the spreading



branches of large woodland trees. The letter *a* shows end of wall, *b* the approximate space to contain compost and roots of plants. At intervals of a few feet the top courses of brick are tied by cross bricks. The front of the wall is shown at *c*, and the woodland trees at *d*, on the south-west side of the wall. Old walls, treated in this way, are charming. When the compost is first placed on the wall care should be taken to firm it thoroughly and to select for the purpose tough, fibrous turf. A few half-rotted leaves are better than peat for adding to the loam as peat does not readily absorb water after it becomes dust dry. Any old favourite plant may be included, but for the benefit of the inexperienced a beginning with the following kinds will answer the purpose. Alyssum saxatile, Achillea rupestris, Arabis albida, Arenaria montana, Aubrietia excelsa, Campanula garganica, Dianthus fragrans, Gypsophila repens, Hypericum polyphyllum, Linum flavum, Nepeta Mussini, Œnothera mexicana, Phlox stellaria, Saxifraga apiculata, sedums and thymes in variety.

THE CARE OF SUMMER BEDDING-OUT PLANTS.

Where glass accommodation is very limited and a rather big stock of bedding-out plants is required, much skill is required in dealing with the plants at this season so that they will be nice, sturdy specimens when the time comes to plant them in the garden. Three good plants are more valuable than five poor ones, so it is wiser to grow a limited number and grow them well, than a surplus which would result in weakly plants. In many small gardens the wise cultivator will make use of a few empty boxes, such as orange boxes, knock out the bottoms and place them on a bed of ashes, or retain the bottoms and place a layer of ashes in each one. It is a very easy matter to cover the boxes at night with sacks, scrim or mats. The full exposure of tender plants, after careful treatment under glass, generally results in a serious check, whereas the boxes will prevent such checks. Cuttings, recently rooted, should be re-potted and retained under glass till they possess a number of roots touching the sides of the pots before they are transferred to outside boxes or cold frames. Very careful watering is necessary and all water used should be placed in a frame, a greenhouse or a sunny corner outside for several hours before it is applied to the plants. Some rotted leaf-soil is very beneficial in the case of tender seedlings and newly-rooted cuttings.

THE TREATMENT OF AZALEAS AFTER FLOWERING.

Many plants are spoiled every year because they are not properly treated after the flowers have faded. While the flowers remain fresh water is applied, mostly, when it is needed, but afterwards the plants are frequently neglected in this respect; they are also allowed to suffer through being infested by red spider and thrips, the two principal insect enemies of these plants. Even while the flowers are fresh the new shoots are growing and, later on, they mature and bear flower buds in numerous cases. If any plants need re-potting, this work should be done at once. Very fibrous loam and peat in equal proportions with a free addition of coarse sand form a suitable compost. The old ball of soil must be thoroughly moistened through before re-potting is done and the new compost must be made firm. Good drainage is essential. Manures are not required. Careful watering and daily syringings will ensure clean, healthy growth. Early in June the plants should be placed outside on slates or ashes in a cool position shaded from the noon sun and facing north. By September the new shoots will be ripe and flower buds formed. I refer to Indian azaleas mainly. GEORGE GARNER.

CORRESPONDENCE

MODERN LUPINS.

SIR,—Since publication of the article under the above title, which appeared in THE GARDEN, February 21st, I am reminded by a peep into Kelway's "Manual of Horticulture" (1901 edition) that so far back as the year 1898 Lupin Somerset was exhibited by Messrs. Kelway and Son and received an award of merit from the Royal Horticultural Society. This was the first recognised hybrid between Lupinus polyphyllus and L. arboreus, and the first herbaceous lupin of a clear yellow colour. In all fairness, Messrs. Kelway's part as pioneers in the production of the modern race of lupins should have been referred to in my article, and I crave leave to rectify an omission for which there can be no justification. Somerset, as I can very well remember, was received with open-armed welcome, and many were the speculations as to the possibilities which this new "break" opened up. During the dozen years or so immediately following the advent of Somerset, Messrs. Kelway and Son worked in their characteristic manner which has made them so conspicuously successful with many popular families, and in the case of the lupin resulted in the production of a fine series of the hybrids, ten of which are described in the Manual of 1913. Canary, as might be anticipated, is clear yellow, but Belle of Huish, Coronation and Phyllis Kelway all gave us a foretaste of the fine blendings of coppery, bronzy and orange tints with lighter yellow which have of more recent years made the modern lupin the highly favoured flower it undoubtedly is. Others of this set are Huish Beauty (purple with a touch of yellow on the standard petals) Langport King (a variety which varied in tint from base to tip of spike, embracing blue, carmine and some white). Porcelain Blue has flowers of the shade indicated by its name with some white in the standard petals. Punchinello is mauve and yellow, and Rod of Ivory is ivory white and creamy yellow. These, or most of them, have the evidence of their hybrid blood plainly imprinted upon them, and some hanker after the arboreus habit.—L. I. ATRIS.

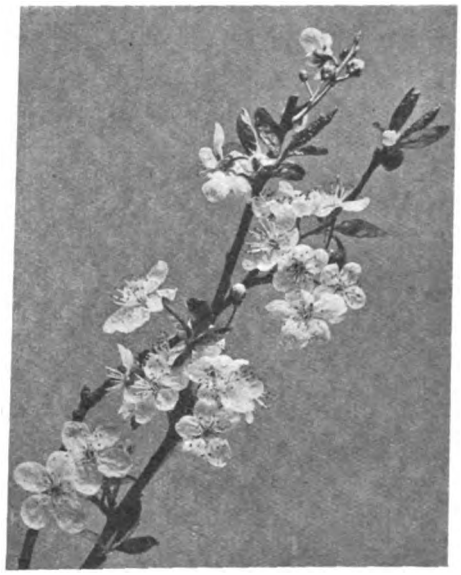
DIGGING AND TRENCHING.

SIR,—The letter from "J. H." (page 107), is interesting, but the suggestion it contains most decidedly does not agree with my experience of well over forty years duration, on ground that is practically all that heavy, poor, tenacious stuff termed "London Clay." If "J. H." can find a much worse medium on which to grow vegetables in the way of soil, well, I should rather like to see it. Yet! This is the ground that has borne the vegetables of the grower to whom he refers. When I first came to Aldenham those many years ago I was informed that the old kitchen garden was "worked out," and it was a poor bit of ground, with but a few inches of impoverished soil on the surface, and this had been scratched over for something over 100 years. I was not satisfied with this statement, and immediately trenched right into it to bring the deep subsoil (clay) to the surface, a practice I have always advocated, and that kitchen garden has been the primest area for the production of the Aldenham exhibition vegetables! I came to the conclusion years ago that the more "poverty struck" the soil, the more need there was for deep trenching and the inversion of the lower spits to the surface, where sun, air, rain, snow, frost, etc., could all play their part in rendering it properly fertile, over and above the fact that such method permitted the working in at the deeper levels of material that would help to lighten the mass, and feed the plants, as well as providing the deep root run so necessary for the proper growth of vegetables in the majority of cases. We have always adopted this principle at Aldenham, and I cannot, in face of actual results, agree with the contention of your contributor, nor alter or modify my previous advice.

If "J. H." would like to see the soil and the area referred to, we should be pleased for him to see it, and the method applied, for, with the results attained, we can be proud of the method, for it has proved a surprise to many who have held similar views to those of "J. H."—E. BECKETT.

PRUNUS PISSARDII.

SIR,—The illustration below of a spray of Prunus Pissardii shows, I think, the beauty of this species. The pinky white blossoms are especially beautiful and show up in contrast to the almost blackish bark of the twigs. The foliage is also of extreme value



PINKY WHITE BLOSSOMS OF P. PISSARDII.

in the shrubbery owing to its coppery purple tints, which almost rivals those of the copper beech.—A. J. PEARSON.

OSMANTHUS DELAVAYI.

SIR,—Mr. Ballard does well to demur (page 133) to my suggestion of Osmanthus Delavayi as a hedge plant, which was not warranted by experience, for I have never seen that charming plant put to that purpose. Moreover, I have since been told that it is not easily propagated by cuttings, which would prove a difficulty in raising a sufficient stock. The fact is that, being disappointed in the meagre crop of berries borne by Lonicera nitida, its amethyst berries constituting in my judgment its only claim to be reckoned as an ornamental shrub, I made random mention of O. Delavayi as a substitute, it being in full flower at the time of writing. A feeble excuse, I own, but it must serve in default of a better.

If I had occasion or room to plant a garden hedge, it should be made of Ribes sanguineum, being led to that conclusion by the behaviour of a large bush in the grass plot before a farmhouse in this neighbourhood which has been a joy to behold for very many springtimes in succession. Standing about 7ft. high, it is closely clipped annually in the form of a dome, yet this treatment does not interfere with the profusion of crimson bloom which it bears year after year. Cuttings of the flowering currant set in September or October strike without fail in the open. There is a wide range of colour in the varieties, from blood-red to nearly pure white, and the hybrid R. Gordonianum might be used to contribute a blend of soft orange.

In common with many other spring-flowering shrubs, O. Delavayi has responded to the abnormal warmth and wet of the past winter by starting its display a full fortnight earlier than hitherto recorded. It began here on March 5th. It appreciates a dressing of lime in the soil.—HERBERT MAXWELL, *Monreith*.

SUCCESS WITH GARDEN PEAS: AN APPRECIATION.

SIR,—I should like to thank Mr. Edwin Beckett for his very timely and interesting article on garden peas. Coming from the pen of one who is the foremost and most successful exhibitor of our time, it is well worthy of the close attention of those who grow this, one of the most useful of all vegetables. It is a fact, as the writer has stated, that one meets with two classes of growers—one who, no matter what improved sorts are introduced, will persist in sticking to the old sorts of peas, that were, undoubtedly, good thirty or forty years ago, but which have long since been outdistanced by immensely better varieties. Talk to these friends about the excellence of modern sorts, and you are immediately met with the rejoinder, "Ah, give me some of the good old sorts like American Wonder and Gladstone." They have nothing to say for the more valuable introductions of the time in which we live. I venture to say that many readers who have had practical experience of the Gladstone pea will be quite in accord with what Mr. Beckett says in regard to its being uncertain in its habits and poor in quality when compared with others of Duke of Albany type. I well remember Mr. Beckett's opinion of the Gladstone, and it is set forth in his book (page 180), "Vegetables and Their Cultivation," now before me. But I think last year, with its long spells of cold and wet, disillusioned many who grew the Gladstone. At any rate, some whom I know, who pinned their faith to it, especially for exhibition, are now looking to other varieties.

No one knows more of the immense value of trenching ground than Mr. Beckett. He practises at Aldenham what he has long since preached, and the success of his work has followed him to the exhibitions of the R.H.S., Shrewsbury, Southport and elsewhere, where those high-class vegetables, so superbly staged, were the admiration of thousands. In my experience of gardening and of shows, extending over very many years, no one, in my judgment, has done more to raise the tone of the vegetable section in the exhibition arena. As a friend of mine said in speaking of the Shrewsbury Show of 1924, at which Mr. Beckett eclipsed even himself, "Nothing but the best will do for Beckett."—W. LINDERS LEA.

LACHENALIAS.

SIR,—May I be allowed to point out an error in the report of the R.H.S. Show of February 24th, as given in THE GARDEN? The title of the illustration "Lachenalia" is misleading and should read "Excelsior Seedlings," as there is a number of varieties in this strain. Also Nelsoni has been in commerce for many years and cannot be described as "raised quite recently." It received an award of merit in 1887, while Siam received a similar award last year.—JOSEPH JACOB.

[We regret the errors and thank our correspondent for having pointed them out.—ED.]

NOTES FROM CONTRIBUTORS

ST. DABEOC'S HEATH.

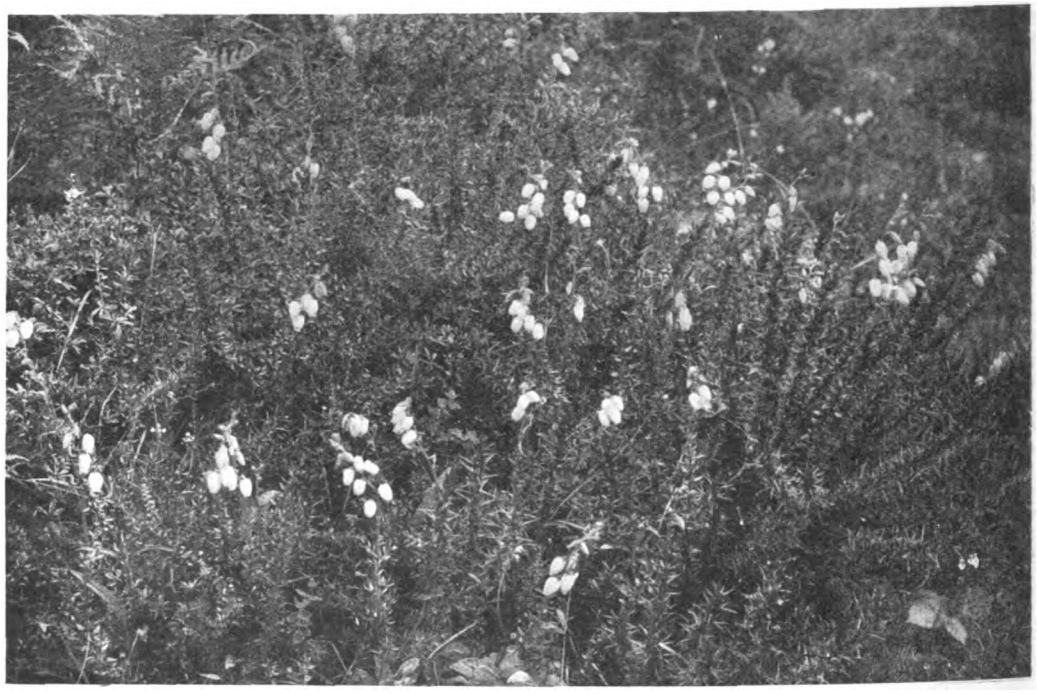
I WAS glad to see in THE GARDEN for February 7th (page 75) your contributor "A. T. J." singing the praise of St. Dabeoc's Heath (or, to quote his title exactly, St. *Daboec's* Heath). It is undoubtedly one of the best of all the smaller ericaceæ. It is as easy as possible, has a better and less straggling habit than most, and a longer flowering period than any. In Connemara, where it is abundant over a large area, it prefers the drier places, mingling with E. cinerea, E. Mackaii and Calluna on banks and delighting in growing up through the dense cushions of Ulex Gallii that populate the less boggy parts. In May it is already in flower, and in October bloom is still frequent. It does not vary much in nature. Darker or lighter shades of blossom occur, and twice I have found a white-flowered plant. Naturally it grows straggly, but, like many other species, it is much more bushy and compact in the garden. Though in its Irish habitat it occupies an area where frost is rare and slight, in the Pyrenees it occurs high up where the winter is severe. In our gardens it appears capable of withstanding without inconvenience any weather that comes.

A word as to its name, both Latin and English. St. Dabeoc was a well known Irish saint of the fifth or sixth century, and abbot of Lough Derg in Donegal, a spot still highly venerated and a noted place of pilgrimage for the devout. His name appears in various forms in ancient manuscripts, but while the prefix may vary, the root word, *Beoc* or *Bheoc* persists, and (this is the point I wish to make) *Bœc* is never found, and would be, indeed, impossible as an Irish word. The first connection of the saint with the beautiful heath which bears his name occurs in connection with the discovery of the plant in Ireland about 1699 by Dr. Edward Lhwyd, Keeper of the Ashmolean Museum at Oxford. This was announced in a letter from him to Dr. (afterwards Sir) Tancred Robinson dated August 25th, 1700 (and eventually printed in the Philosophical Transactions for 1712). He did not there mention any name for the plant, but John Ray, in his "Historia Plantarum" (Vol. III, Dendrologia, page 98) quotes him for the statement *Erica S. Dabeoci Hibernis*—"the St. Dabeoc's Heath of the Irish": this was in 1704. When Linnæus came along with his binomial names ("Species Plantarum, ed. 2, page 509, 1762), he quoted Ray as above, but named the plant, not Erica *Dabeocii* as he ought to have done, but Erica *Dabœcii*. How this happened it is impossible to say—perhaps it was a *lapsus calami*, perhaps an uncorrected compositor's error. (Even Linnæus could nod, for, as a matter of fact, he misquotes Ray, writing *Dabeci* instead of *Dabeoci!*). But the damage was done, and when David Don in 1834 placed the plant in a separate genus, he followed the Linnæan spelling, and called the genus Dabœcia instead of Dabeocia, being no doubt unaware of the facts of the case. Under the international rules of botanical nomenclature a name once duly given cannot be changed, even if given in error. So if we want to be strictly law-abiding, Dabœcia must stand as the botanical designation. But if we cannot now make the Latin name right, we certainly have no justification for making the English name wrong, and the plant remains St. *Dabeoc's* heath. Even as regards the Latin name, it seems a not very serious crime to follow C. Koch ("Dendro-logie," II, 2, page 132), who in 1872 corrected the name to Dabeocia. The plant is one of that very interesting group which includes the arbutus, London pride and Cornish heath—that grows in the Pyrenees or along the Mediterranean, and also in south-western England or in Ireland, and which appears to be a relic of a time when a continuous coast line and a milder climate allowed them to spread freely along the western edge of a larger Europe.—R. LLOYD PRAEGER.

[The mistake in the title of the article in our issue of February 7th was due to a printer's error.—ED.]

PABCO THERMOGEN MULCH.

RECENTLY there has been a great deal said about this new mineral mulch, which appears to have proved a great success on the pineapple farms of America. To test its efficiency an experiment was conducted in these gardens with Tomato Golden Queen, with a view to comparing the amount of water supply and weeding necessary between two observation beds, one of which was dressed with the mulch. The result was very promising and showed that the mulch minimised evaporation, with obvious benefit to the soil and considerably reduced the necessity of watering. The growth of weeds was made impossible and the ground surface did not cake. The mulch appeared to have some influence on the plants, for the growth was more vigorous than the check bed and the fruit ripened quicker. The yield was also greater than the unmulched bed.—R. LEDLIE, *Government Horticultural Gardens, Lucknow.*



THE ST. DABEOC'S HEATH, OF MORE OR LESS STRAGGLING HABIT.

MENDEL TULIPS.

NO retail British list that it was my fortune to come across in the autumn of 1924 contained any offer of this new race of tulips, either in separate varieties or in mixture. Hence I am possibly not far wrong when I suggest that few people know much about them.

They are the result of crossing Duc van Thols with Darwins, and were one of the last big contributions—if not the very last—that the now defunct house of Krelage of Haarlem made to our garden bulbs. I am trying some under glass and some in the open ground. Those under glass were bought as "mixed." The few named varieties which I "ran to" were very much more costly and were all planted out of doors. Of these more, when I see how they behave and what they are like. The mixed ones, grown in pots under glass have been a decided success. One hesitates to make any sort of ex cathedra pronouncement upon their future with the limited experience of one season, but I feel I am well within the mark when I advise those who like to have tulips with decent stems in the early part of February to give them a trial. I mean those who, like myself, have but little heat at their command. They know full well the sight of arrested growth with swollen looking stunted blooms bursting out of bits of green, which in happier circumstances would be stem and leaves. They know the pitiful sight only too well and "learned" by repeated failures have given up trying to grow them. Mendel tulips hold out the olive branch of hope. That, at least, is my summing up of my present experience. Treated in every way like some early-flowering varieties which had been planted for comparison, they threw up decent stems and good flowers, while they (the ordinary earlies) were miserable failures. There were no yellows, but there were all manner of red shades. Some were taller and some shorter. Some had quite an agreeable perfume. To parody Lancelot Brown I would say of these new comers, "They have great potentialities."—JOSEPH JACOB.

ASPARAGUS UNDER DIFFICULTIES.

THE growing of this popular and highly desirable vegetable has probably caused more worry and disappointment to gardeners and their employers than almost any other crop one can mention. Bed after bed has been planted in successive years, and

Digitized by Google

in many cases the results have been so poor that the attempt to grow it has been abandoned and the usual conclusion come to is, "Oh, asparagus will not grow here." Most gardeners know of such places. No doubt certain places are better adapted for the growing of asparagus than others, but there are few places, if any, where it cannot be grown with considerable success.

The accepted formula is to prepare the ground well as to drainage, manuring, pulverising, etc., then either buy in plants or have them previously at home and plant in April, and under the necessary conditions this plan succeeds generally. But great care has to be used in the work, and very often the results are not anything like in proportion to the care and labour expended.

The writer has been in two places where he was assured asparagus could not be grown, and as he has been successful in having good asparagus in both (the first lot now over twenty years old) he hands on the information in the hope that it may be useful to some readers of THE GARDEN.

The site should, of course, be the best available. Soil as light and well drained as possible, the exposure as nearly south as may be and not too exposed to rough winds. The preparation is much as for planting. Work in plenty of old manure, bones, burnt soil and sand as can be spared. Trench or double dig at least 2ft. in depth, breaking up and adding to both spits. If the bottom spit is not so good as the top, leave it below and add plenty of opening material to it. Leave the surface rough till April, when it should be well broken up with digging forks and the whole made level.

The beds should be about 5ft. wide, leaving an extra foot for an alley between each, these not being formed the first year. Have the drills drawn out as for any seed of the same size, say, 1½ins. in depth and 18ins. apart, and place the seeds separately therein about 4ins. to 6ins. apart.

It is well to put good stout pins either at the ends of each row or at the corners of each bed so that the exact position of rows may be easily found. When the young plants appear keep the ground well stirred and free from weeds with the Dutch hoe to promote a rapid and healthy growth, and when large enough thin out to 12ins. to 18ins. apart. Place twigs round each for support and encourage by every means during the growing season. After the tops die off in autumn give a good mulch all over the bed of some good short manure, stable manure being best for heavy soils.

The second spring, spread a good coating of rough sand over the mulch and fork the whole into the surface soil of the bed. Attend to staking and cultivating as before during the second growing season, and repeat mulch in autumn.

The third year the alleys may be formed and the soil used to raise the level of the beds. A good dressing of salt or sulphate of ammonia may be given in this and subsequent years. If anything like success has been attained, a moderate cutting may be had on this, the third, spring, and thereafter a plentiful supply should be available. Where ground is to spare a bed should be sown each year, when one of the older ones may be lifted and forced for early supplies.—NIL DESPERANDUM.

EARLY FLOWERING BULBS ON THE ROCKERY.

WHETHER or not bulbs are out of place on a rockery is, perhaps, a matter of opinion; but, whatever arguments are raised in objection, it cannot be denied that the majority of the earliest flowering plants on a rockery are either bulbs or corms.

Having had a lax spell as far as blooms are concerned, it is with delight we witness the appearance of these floral "heralds of spring."

On taking a walk through the rock garden in the month of February, one is immediately struck by the beauty of the modest snowdrops, prominent species in flower being Galanthus nivalis (the common snowdrop), the stately G. plicatus (a native of the Caucasus), the large-flowered G. Elwesii, and the broad-leaved though rather small-flowered G. latifolius.

Growing in close proximity to these the lovely blue flowers of Scilla bifolia and, a few days later, S. sibirica provide a pleasant freshening of colour.

Supporting the blue, the diminutive yellow-flowered narcissus minor var. minimus calls for admiration; while among a number of crocuses, C. Balansæ, C. chrysanthus var. albidus and C. Imperati strive for supremacy. Bulbocodium vernum, though perhaps not so neat and attractive, is, nevertheless, a welcome February arrival, and Cyclamen Coum is also present. The snowflake, Leucojum vernum, and its variety, L. v. carpaticum, are now much admired for their unique, drooping, bell-shaped blossoms.

Iris reticulata var. histrioides was the first of the genus to appear, but some of its brethren are on the verge of opening.

Those in the south will probably be favoured with a far greater variety than is contained in the foregoing list, but let me state that we in the north would wait long enough for blossoms in the rockery were it not for the boldness of the bulbs.—W. H., *Glasgow.*

PHOSPHATE OF AMMONIA
PHOSPHATE OF POTASH
Very concentrated, especially suitable for high-class Gardening Fertilisers
PERRY & HOPE, LTD., Nitshill, nr. GLASGOW

Whitley and Monkseaton Urban District Council.

TENDERS are invited for the supply and delivery to Monkseaton Siding of GOOD QUALITY TURF, suitable for Bowling Greens.

Quantity required 1,700 square yards.

Tenders, sealed and endorsed "Turf," stating price per square yard (to be measured when laid on the Green) together with a sample of the turf to be supplied, to be sent in to me, the undersigned, on or before noon of Monday, the 30th day of March, 1925.

The Council do not bind themselves to accept the lowest or any Tender.

ARTHUR BARKER,
Clerk to the Council.

Council Offices,
Whitley Bay.
14th March, 1925.

Don't Burn Your
GARDEN RUBBISH
MAKE IT INTO
SYNTHETIC FARMYARD MANURE
By the ADCO Process
(Patented in the United Kingdom and Abroad.)

During the past two years some thousands of gardeners have treated their vegetable refuse of all kinds with **ADCO Accelerator**. The resulting manure has given general satisfaction under very varied conditions as regards soil and climate. Whenever sufficient green vegetable waste, *e.g.*, grass cuttings, weeds, etc., are collected to form about half the heap.

ADCO ACCELERATOR
is the best and cheapest means of converting this into an organic fertiliser equal to or better than farmyard manure.

If your Dealer does not stock ADCO write direct to us, mentioning his name and nearest Goods Station

56 lb. of ADCO Accelerator make One Ton.

BOOK REVIEW

REFERENCE has often been made in these pages to the books of Dr. L. H. Bailey and the high standard of excellence which is attained in all the volumes of which he is the author. This latest work, "The Principles of Vegetable Growing," by Dr. L. H. Bailey, published by the Macmillan Company, New York, price 20s., is not a new volume, but is a completely revised edition of the original, which was published in 1901. The excellence and general practical value of the book is testified by the fact that this is the eighteenth edition. It treats comprehensively of the general principles underlying the raising of vegetable crops, the plants themselves, the diseases to which they are subject and their ordinary culture. Chapters are devoted to the forcing of vegetables and their treatment under glass and in hotbeds, with notes on the general management, the land and its treatment with reference to the tools to be employed. A chapter which is both interesting and instructive is that on seeds and seedage, dealing with their testing, growing and sowing. Finally, a chapter on marketing, storing and drying, together with a complete index brings one to the end of the volume. The personal and human interest is kept to the fore throughout its pages, a most necessary fact when one is dealing with an important economic subject. Criticisms might be levelled at certain omissions, but the limits of a single handy book on the subject, such as this volume is, precludes the introduction of a mass of detail in vegetable culture. Readers in this country should bear in mind that the advice given is based on conditions in America, but nevertheless the general principles laid down will be found to apply equally well in this country. It is a sound practical volume and should be thoroughly appreciated by all gardeners, both professional and amateur.

Norfolk and Norwich Horticultural Society.—The annual meeting of this Society was held in the Guildhall, Norwich, on February 14th. The Lord Mayor of the City presiding. The report commented on the Spring Show of 1924 as the finest display of spring flowers ever held in the city. The day of the Summer Show was the wettest for all July and most materially affected the "gate" receipts. The Chrysanthemum Show was well patronised. Reference was made to the loss of Mr. Sydney Morris, Lord Ailwyn and Lord Suffield, all of whom were patrons and exhibitors at the Society's shows. In presenting the statement of accounts Mr. Herbert Perry, one of the auditors, pointed out the set backs to income during 1924, nearly £120 was lost owing to the wet day of the Summer Show and the public had not patronised the Spring Show as one had hoped, consequently the Society was in deficit to an amount of over £60. Sir Bartle Frere was elected president for 1925 upon the proposal of Captain J. H. Mander. On the proposal of Mr. H. Perry the vice-president elected for the year was Mr. J. E. Moxey, Framingham Hall. Captain Sandys Winsch, Parks Superintendent was re-elected Secretary. It was decided to hold a one-day Spring Show in Norwich at the latter part of April, the date of the Summer Show was fixed for June 25th, and the Autumn Show near the end of November.

"The Journal of the Kew Guild for 1925,' Vol. IV, No. XXXII. The Journal serves as a link between present and past Kewites and stands for an object which all men who have passed through Kew Gardens should support. To men whose years of training are now but a fragrant memory, the Journal comes as a refreshing and invigorating tonic, containing as it does all the news of their *alma mater*. There are many interesting features in this volume, apart from general news of members and bulletins, such as an interesting article on The Botanic Gardens at Singapore, by the Director, Mr. I. H. Burrill. The Journal is well printed, and to the editor, Mr. Ernest Dunk, we offer our congratulations on the excellence and general usefulness of the volume.

CATALOGUES RECEIVED.

Messrs. Barr and Son, King Street, Covent Garden, W.C.2.—List of Hardy Perennials, Rock Plants, Hardy Climbers and Wall Shrubs.

Messrs. Maurice Prichard and Sons, Riverslea Nurseries, Christchurch, Hants.—Herbaceous and Alpine Plants, Shrubs and Climbers.

Clarence Elliott, Six Hills Nursery, Stevenage.—Seeds of choice Alpine and Herbaceous Plants.

Messrs. Stuart Low and Co., Bush Hill Park, Middlesex.—Carnations for 1925.

J. W. Crow, Simcoe, Ontario, Canada.—A List of Choice Gladioli, including many new varieties, fully described, with notes on culture.

Messrs. Allwood Brothers, Haywards Heath, Sussex.—A Spring Catalogue that all carnation lovers should have. During the past year Messrs. Allwood have scored many new triumphs. One of the hits of the season is undoubtedly the raising of the new Bizarre Seedling Perpetual Border Carnations, which are of hardy constitution and should do excellently in all positions, provided free drainage is supplied. A few novelties in their Allwoodii strain are described, and these appear to be a distinct advance on any of their predecessors. With the acquisition of new varieties in all shades and tones of colour, this race is becoming increasingly popular in the garden.

An omission was made in the report of the R.H.S. Show on March 11th. The Freesia Wistaria shown by Mr. Dalrymple gained a first class certificate.

LOBELIA HUNTSMAN
Finest of the Scarlet Cardinal Flowers.
NOW is the Time to Plant.
1/6 each, **15/-** dozen, **100/-** 100
T. SMITH, Daisy Hill Nursery, Newry, Co. Down

County Borough of Southport
The SCHEDULE for the SECOND GREAT ANNUAL
Southport Flower Show
——is now ready——
THE SCHEDULE CONTAINS —A LIST OF JUDGES—
The 23 Silver Challenge Trophies, the Medals and Cash Prizes offered, represent a total — amount of over £2,900 —
Spaces 15ft. by 10ft. will be provided inside the Show Ground for Exhibits of HORTICULTURAL SUNDRIES at —— £5 per space ——
Schedules and plan of Show ground showing the positions for the Horticultural Sundries exhibits, may be obtained post free on application to the SECRETARY, FLOWER SHOW, TOWN HALL, SOUTHPORT.

HERBACEOUS PHLOXES : :

(Please see article on page 174)

This is the time to plant these useful Autumn Flowering Plants. The selections below represent the best of their colours, and will be found thoroughly reliable and satisfactory.

12 Phlox, 9/-
(Carriage Paid)

	EACH
Baron van Heeckeren, new salmon	1s.
Europa, snow white, carmine centre,	8d.
Evelyn, large salmon pink, extra	1s.
Fireglow, brilliant orange-scarlet	1s.
Homeland, brilliant orange-red	9d.
Jules Sandeau, handsome dwarf pink	1s.
Le Madhi, rich dark violet	9d.
Mia Ruys, handsome dwarf white	1s.
Mrs. M. Van Hoboken, large soft pink	8d.
Rheinlander, salmon-pink, splendid,	9d.
Thor, salmon-red, red centre, splendid	9d.
Vald Jensen, salmon-red, white star	1s. 6d.

One each above Strong Plants, 9s. 12 threes, 25s. 6d.
(Carriage Paid)

12 Phlox, 6/6
(Carriage Paid)

	EACH
Baron van Dedem, clear scarlet-red	6d.
Eclaireur, carmine-violet, early	6d.
Eliz Campbell, lovely pale pink	8d.
F. A. Buchner, perfect pure white, extra	8d.
G. A. Strohlein, fine orange scarlet	9d.
Gen. van Heutz, salmon red, white star	6d.
Jos. Gerbaud, snow white, cherry eye	8d.
Marechal Foch, bright crimson-red,	8d.
Mad. Paul Dutrie, soft pale pink	8d.
Mons. Kind, orange-scarlet, first rate	6d.
Rijnstroom, large handsome pink	6d.
Selma, pink-cherry, red eye, fine	9d.

One each above Strong Plants, 6s. 6d. 12 threes, 17s. 6d.
(Carriage Paid)

APRIL 4, 1925

THE "COFFIN" TREE

THE Chinese are well known for the respect which they give their elders, amounting, in fact, to ancestor worship. Among other acts of reverence towards parents and grandparents the rich spend large sums in providing and decorating coffins, and even the poor will mortgage all they have in order to give a fitting burial. Many coffins are extremely elaborate, and there is no doubt that some of the best lacquer work that the Chinese have produced is on coffin lids. It is known that several woods are used in the manufacture of coffins, among them various species of conifers. Farrer and I discovered in Upper Burma an instance of the length to which the wealthy Chinaman will go in order to supply a suitable coffin. While collecting around the Hpimaw pass we constantly met long streams of coolies each bearing on his back a single plank about 7ft. long, 3ins. thick and about 3ft. in width. As we had seen no signs of cutting of timber in our neighbourhood, we made enquiries and found out that there was a great export trade to China of these planks from the area behind and north of that in which we were working. This trade was apparently of great age, and, although we saw no full-grown trees, there is little doubt that, while always solitary, the tree from which the planks came was at one period scattered up and down the frontier and may have spread far into the tangled ranges of N.W. Yunnan. Now, however, the supply must be extremely small and is limited to hidden interior valleys where no white man has ever penetrated. Even the officers in charge of the district have never seen a large specimen.

The woodcutters apparently cut down the tree and carve out the planks with the sole help of an adze, for both axe and saw are unknown, consequently the wastage of material must be enormous. Probably the coolies had carried these planks some fifty miles when we met them, and it is certain that their nearest destination possible was Yunnan-fu, a distance of perhaps 400 miles to the east. Yet with all these difficulties this is apparently a flourishing trade, and at the time we were there the Chinese were willingly paying from £50 to £60 for a single plank.

The tree which these planks came from is a species of juniper. We came across a small tree about 50ft. in height and only about 20ins. in diameter 4ft. from the ground. The only other remains that we saw was the shell of a tree obviously destroyed years before by lightning. We took shelter in the shell from a rainstorm, and sat inside in comfort. Indeed, from the marks of fires on the floor, it must have been a favourite resting place for travellers over the Chimili Pass. The diameter at 4ft. above the ground must have been about 5ft. As the tree is never unwieldy in size of trunk, the height of this giant must have been over 150ft. This makes it at least 50 per cent. larger than Juniperus virginiana.

Farrer describes it thus in his field notes: "I have hopes that this may prove the most important economic introduction for very many years past, for it is a, presumably, *hardy*, superior at all points to J. virginiana, which it ought to drive off the market for 'cedar' oil, 'cedar' cabinets and 'cedar' pencils. It is, besides, a remarkably lovely, graceful, weeping, grey-green 'cypress' occurring rarely in the ravines of woodland, never under 10,000ft. in a region where the summers are wet and sunless, the winters are alpine cold, and the springs late and ungenial and chilly. The wood is close and fine in grain, immortal, and of the most delicious fragrance, either fresh or burned in strips."

Although Farrer may have been too optimistic regarding the value of this tree from an economic standpoint, I can fully bear out these eulogies. I believe the reason why it is so prized by the Chinese is that it takes lacquer better than any other wood. We sent home pounds of seed, and, although only a few germinated, yet it is easily propagated by cuttings, and it is already listed by several nurserymen either under the name "coffin tree" or under number Farrer 1407. I have had several seedlings in my nursery on the east of Scotland without any winter protection for two years, and I have found it perfectly hardy, although rather slow growing. It is, however, most attractive at any size, for even at 3ins. high it takes on its typical weeping appearance. Although it is still too small to have been thoroughly tested, it appears that any rich loam suits it, but I should say that it should be planted in a position distinctly shady while it is young.

THREE INTERESTING PLANTS

BY CAMILLO SCHNEIDER.

ASPIDIUM BRAUNII.

AMONG our hardy ferns, Aspidium—or as it is very often called, Polystichum—Braunii (not Brownii), is a well known species widely distributed over the whole northern temperate zone. It is found in shady woods, often on rather stony slopes. It thrives best in a good, deep, light but not spongy loam, well mixed with humus, and it needs shade on account of its rather thin leaves. Its fronds are not evergreen, but die in late autumn or during the winter. Their texture is by no means leathery, as in A. lobatum, and distinctly softer than in A. aculeatum, of which it is often regarded as a variety. Of the true aculeatum the leaves are evergreen, but not leathery. But A. aculeatum, A. lobatum and A. angulare really form one species, showing the greatest variability possible. A. Braunii, however, is not at all variable, and those forms that seem to be intermediate between Braunii and aculeatum and its subspecies angulare and lobatum are now considered as hybrids. The illustration gives a good idea of the pale green, thin, and soft fronds of A. Braunii, which usually reach a length of about 2ft. (sometimes almost 3ft.). The scales of the rachis are of a lighter brownish colour and the number of the pinnæ usually do not exceed fifteen on each side.

By its light green deciduous fronds A. Braunii is easily distinguished from the species most closely related to it, possessing fronds that are bi-pinnate in the lower two-thirds. Other hardy species of the polystichum group with roundish sori, like A. acrostichoides, A. Lonchitis or A. munitum, have simply pinnate fronds, while those like A. laserpitiifolium have the fronds three to four pinnate in the lower two-thirds.

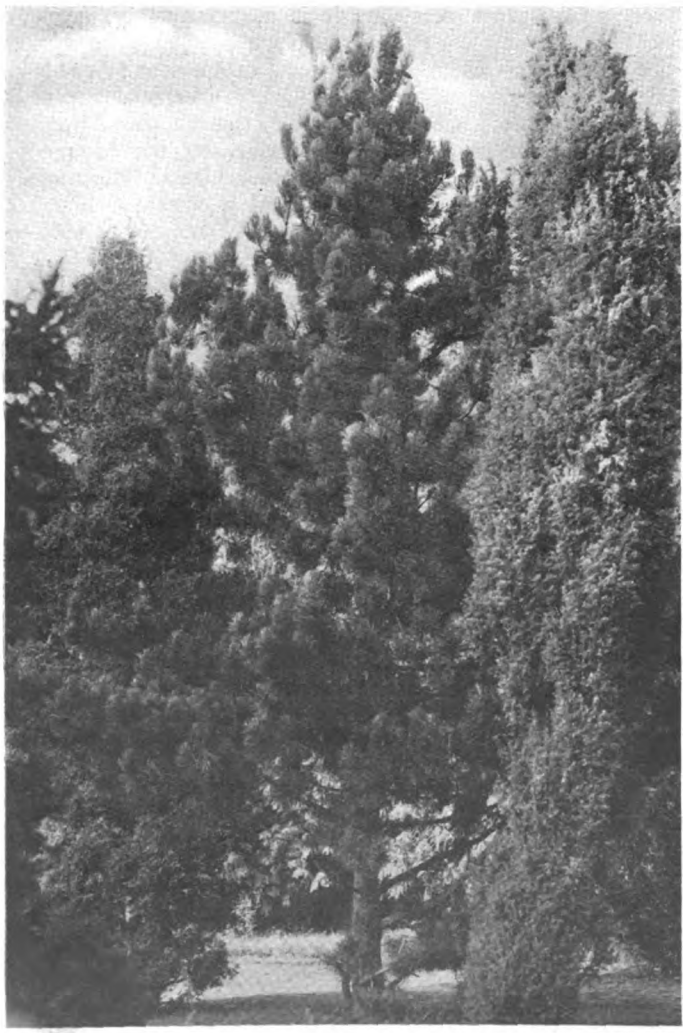
THE PALE GREEN DELICATE FRONDS OF ASPIDIUM BRAUNII.

Of the wild types, A. Braunii can be highly recommended for cultivation in a suitable shady corner of even the smallest garden.

PINUS LEUCODERMIS.

Many years ago while I was travelling in the mountains of Bosnia I had the opportunity to observe this little known form of the widely spread and variable Corsican pine, P. Laricio, or as it is now called, P. nigra. Of this pine the well known variety austriaca or nigricans forms large forests in south-eastern Europe, from the vicinity of Vienna to Galicia in the east and Croatia in the south. It grows well on rather barren limestone mountains and is of greatest value for forestry purposes in such places. It needs a somewhat warmer climate than the common Scots pine, but nevertheless does well even in the colder parts of central Europe.

In 1864 Antoine described a new black pine from Bosnia, Serbia and Albania as P. leucodermis on account of the whitish appearance of the bark of older trunks. This pine was found a few years ago by Heldreich in Greece on Mount Olympus. It was named P. Heldreichii by Christ, who later reduced P. leucodermis to a variety of Laricio. Other names have been given too, to this interesting and critical form, as for instance, P. Prenja Beck and P. pindica Formanek. After all there is still a difference of opinion among botanists as to the systematic position of this pine. The main features in which it is said to differ from P. nigra are its light grey bark which breaks into angular plates and is described as "schlangenhautähnlich gefeldert," its resin ducts not being surrounded by strengthening cells, and by the colour of the umbo of the cone-scales which is greyish-brown on both sides, not only beneath. The ashy-pale, hardly whitish colour of the stem is, the most reliable character of this pine when seen in its native country. I failed to observe it distinctly on cultivated specimens.



THE OLDEST SPECIMEN OF PINUS LEUCODERMIS.

The accompanying photograph shows the oldest but not the largest cultivated plant of P. Heldreichii or leucodermis. It stands in the arboretum of the famous park of Prince Liechtenstein at Eisgrub in Moravia. It was brought to Vienna in 1864 as a very small plant from Bosnia, and it had been cultivated in a large pot for twenty-four years until 1888, when it was planted at Eisgrub. This accounts for the plant being rather small for its age.

SOPHORA JAPONICA PENDULA.

During wintertime the characteristic features of some trees are even more obvious than later when the branches are covered with leaves. Especially is this the case in early

Digitized by Google

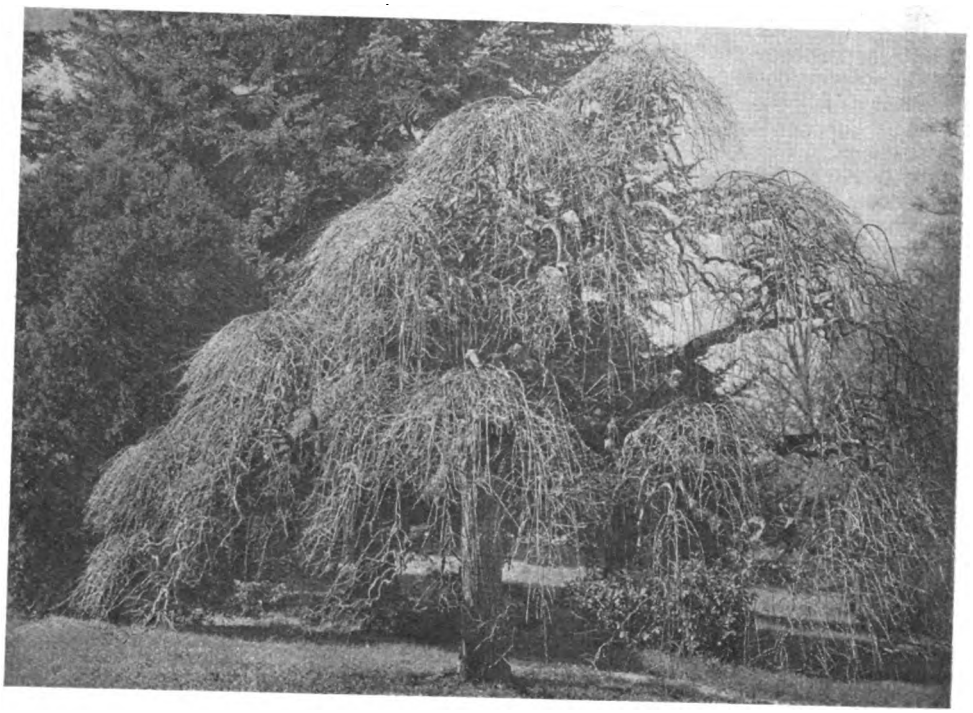
spring in such pendulous trees as Salix babylonica or in a still higher degree, S. alba vitellina pendula, which are very conspicuous when the young branchlets become intensely coloured. They light up among the other dark leafless trees, and form a very striking feature in the landscape.

Next to the weeping willows the pendulous form of our common ash, Fraxinus excelsior pendula is a beautiful tree often met with in our gardens. One of its forms called aurea also has yellow branches like the willow mentioned. The habit of the ash is a good deal stiffer, and not so soft and graceful as of the willow.

The pendulous tree shown in our illustration is in some respects not unlike the weeping ash, but is otherwise very different from it and from the willow, too. It is a form of the Japanese sophora, S. japonica pendula. Even the common form of this good summer-flowering tree has a rather picturesque habit, but more so the weeping variety of which the pendent branchlets are as stiff as those of the ash, but rather short, and of distinct greenish colour. As a single tree on a lawn it is often noticeable, and being of medium size it easily finds a place even in a small garden.

The largest pendulous tree we have is, of course, the weeping red beech, Fagus sylvatica pendula, a large specimen of which seems to imitate a waterfall, sometimes one of our pendulous elms may grow tall, but I have never seen a weeping elm that could match a weeping beech. Is not it rather strange that we do not have a real weeping tilia? There is no weeping form of the black poplar, either. The aspen, Populus tremula, has a form with drooping branches. It is very conspicuous, too, in the early spring on account of the reddish young catkins.

The finest pendulous tree with beautiful flowers is certainly Prunus pendula, or as it is now called, P. subhirtella pendula. There are several other prunus with pendent branches, but none of them is as handsome as this Japanese cherry.



THE EXCELLENT WEEPING VARIETY OF THE JAPANESE SOPHORA, S. JAPONICA PENDULA.

EARLY-FLOWERING CHRYSANTHEMUMS

FOR A BRIGHT DISPLAY OF COLOUR IN THE GARDEN IN AUTUMN, THERE ARE, WITH THE EXCEPTION OF DAHLIAS, NO MORE POPULAR SUBJECTS THAN CHRYSANTHEMUMS.

ALTHOUGH the dahlia is now a serious rival of the early-flowering chrysanthemum as "The Queen of Autumn Flowers," the latter will still retain a large circle of admirers. The reasons for the popularity of the early-flowering chrysanthemum are not far to seek. It is not an exacting flower, as it does not require continual attention like some of our popular garden subjects—for instance, the sweet pea. It can be used in a variety of ways, either for filling gaps in the herbaceous border which arise when summer-flowering plants cease blooming and can be cut down, or for massed effect in beds and borders where it is the sole occupant. Those who possess a greenhouse, whether heated or not, can have a succession of bloom into the dark days of late October or early November when flowers are scarce by growing a number of the later-flowering "earlies" and lifting them into pots, boxes or the greenhouse border. They fill a gap before the decorative varieties commence to bloom, and the old "stools" can be removed to the cold frame after the last sprays are cut, thereby making room for later varieties.

Chrysanthemums do well in an open, sunny position that is sheltered from prevailing winds by hedges, fences, walls, etc., but it is advisable to keep them away from overhanging trees. The soil should be forked over to a depth of 2ft., and well rotted animal manure and bone meal incorporated at the same time. Too many cases of indifferent displays can be attributed to insufficient soil preparation. As the chrysanthemum is easy to grow, it is a common belief that no preparation of the ground is necessary. It is true that they will bloom if left undisturbed for a number of years, but the quality of bloom from such plants cannot be compared with the excellent results obtained from a thorough preparation of the soil and the renewal of stock.

The preparation of the site should be done as soon as weather conditions will allow to enable the soil to settle down before planting out commences. The time for planting out depends to a large extent on the season and the locality. As soon as all fear of destructive frosts is removed, the plants, after they have been well hardened, should be planted out very firmly. For massed effect they can be placed closer than if specimen plants are desired for the production of cut bloom. Stake the plants as soon after planting out as possible and secure them by two or three ties of raffia. If the period following planting out is likely to bring a continued spell of dry, east winds and the situation is exposed, it is a good plan to place round each plant some slight protection in the form of twiggy growths cut from birch, hazel or alder. During a period of drought in early summer it is sometimes necessary on light soils to water the plants. This should be done in the evening, and it is best to give a thorough watering once a week rather than several light sprinklings each day. The appearance of withered leaves on the lower portion of the stem is a sign of dryness at the roots in the growing period.

During the later summer months, as the plants near the period of blooming, light doses of diluted liquid manure or some artificial fertiliser may be given.

Of old favourites the following are reliable in almost any locality or situation, and they are all of easy culture and very floriferous. Most of them are among the first to bloom, commencing to flower in August in Southern gardens and in early September in the North.

Polly is a lovely shade of deep orange, shaded with amber. It is always a mass of bloom during its flowering period, and as the plant rarely attains a greater height than 2½ft., it requires

Digitized by Google

little staking. From Polly we have its sports, Crimson Polly (crimson red), Golden Polly (golden yellow) and Abercorn Beauty (deep bronze). Another favourite is Diana, which is of similar habit and blooms about the same time. It makes a fine bushy plant when well grown. The colour is crimson and gold. Golden Diana and Crimson Diana are two fine "sports," the former being particularly good. The "Masse" family is noted for its very floriferous character. All this type are very easy to grow and are most suitable for town or suburban gardens. Improved Masse, a large rosy lilac with a silvery reverse, will give splendid sprays when well treated, and it can also be disbudded if large specimen blooms are required. I am not very fond of its colour. John McAlpine is one of the best of this type. The colour is a pleasing shade of amber and fawn. Others of similar character are George Bowness (crushed strawberry), Horace Martin (yellow) and F. G. Partridge (an improved form of White Masse). Nina Blick, a distinct variety of bright scarlet-red colouring with a flush of golden bronze, is another good old favourite among the very early flowering type.

Following on we have Goacher's Crimson and its "sports" Bronze Goacher and Mrs. J. Fielding (chestnut red), Normandie (blush pink) and Bronze Normandie, a lovely fawn "sport" from it; Chaldon (reddish crimson), very free flowering; Lichfield Pink and Lichfield Purple, both capable of giving very large blooms when well grown; Silver Lining, a very delicately coloured variety, white, with a soft suffusion of pink as though the bloom had been frosted over with this colour; and the rich burgundy crimson coloured Dick Barnes. Most of these varieties are at their best in September, although in the extreme north and in a late season many of the best blooms open in October.

If weather conditions will allow, a succession of outdoor blooms, the following may be used to form the late September or early October crop in a normal season: September White, a large-flowered white that is good either disbudded or in sprays; La Pactole, a big bronzy yellow flower; Pluie d' Argent, a dwarf but very free-flowering white; and Almirante, scarlet-red with gold tips. The latter pays for disbudding, and if it can be lifted the colour is softer when opened under glass and particularly fine in artificial light. All these varieties may be used for lifting. In smoky districts, or if the autumn is not likely to be fine, it is safer to house them, as the whites become very dirty after a few showers.

One of the finest of the new early-flowering varieties is Alexander A. McAlpine, a rich golden orange with shadings of pale bronze. The individual flowers are large, even when it is grown undisbudded, and it is sufficiently free-flowering to make it useful for sprays.

Saracen was in bloom with me in August before any of the others opened. This is one of Mr. Woolman's 1924 novelties. It is a well built bloom of rich amber colouring with a deeper centre, and it lasts in good condition for a considerable time. Shirley Blush is also a very fine double variety from the same source. It opens a creamy blush, but soon changes to pure white. It is excellent when grown in sprays.

Charlotte Harley and Jessie McAlpine are two fine new varieties from Tollcross. Both are very good. The former is a distinct shade of scarlet-crimson and the latter is blush pink in the open and white when bloomed under glass. Jessie McAlpine belongs to a new type. The florets are narrow and pointed. Even when undisbudded huge flowers can be obtained, and the closely packed centre takes nearly a week to open under glass, so that the blooms will last three weeks in water if cut in the half-open stage. Mr. McAlpine allowed me to grow an advance trial of two of his next season's novelties, viz., Mary Houston and Euphie Ritchie. The former is an improved form of Goacher's Crimson, with a brighter and richer sheen of red; the latter is a tangerine form of Jessie McAlpine. Both are worthy additions to the early-flowering section.

I cannot omit the single varieties, as to my mind these are as beautiful, and perhaps even more graceful for room decoration, being particularly pretty in sprays. There are, however, some fine new additions, which not only have the advantage of better petals, but give large individual blooms which are carried on erect stems. There is now a wide range of colours among the newer single varieties, and most of these are very beautiful in artificial light. Of the varieties I have grown during the past season the best are Delice, a rich shade of bright pink; Morning Star, golden amber; Shirley Terra Cotta, a particularly beautiful shade of terra cotta; Stanley Baldwin, wine crimson; Vicar of Shirley, deep bronze; Dolly Thorpe, salmon apricot; Simplicity, white; and Shrapnel, orange terra-cotta. The last three are standard varieties.

NORMAN LAMBERT.

EUROPEAN PRIMULAS

(*Continued from page* 169.)

PRIMULA MINIMA.—Locally distributed in the east and central Alps, among other stations, we have this delightful species, which frequents high alpine pastures on both granite and limestone, but chiefly the latter. It is a jewel for the alpine lawn or for companionship with Gentiana verna and the like, and forms itself into a compact dwarf mat not more than an inch high, with small, glossy, wedge-shaped leaves that are more or less jagged on the distinct square ends. Flowers of a rosy pink colour arise singly on half-inch stems, and are deeply divided; these appear about June. Scree mixture is quite suitable for its welfare, and it should have abundant water during the growing season.

PRIMULA × BERNINÆ HAS DEEP PINK FLOWERS.

P. GLUTINOSA.—Although abounding in its native habitats, this plant is not often met with in cultivation, probably due to conditions it enjoys, but not always allowed it. The moraine or underground watering system seems most suitable, this species being particularly fond of moist places. It occurs on granitic formations in the high Alps, and very much resents lime. The leaves are coated with a sticky substance and are ovate in shape. The flowers, which are of an intense violet colour, are borne in heads on dark stems that grow to 3ins. or 4ins. in height.

Digitized by Google

P. ALLIONI is one of the greatest treasures of the race, but requires almost ideal conditions to make it happy, In nature it seems to prefer positions where the sun cannot strike it direct; still, it will stand a good deal of sunshine here, and thrives with it, but I think the surest aspect is a northerly one, where it can be planted under a slightly overhanging rock so that excessive overhead wet cannot reach its foliage. It delights in a deep limestone crevice, where it can firmly wedge itself and where plenty of water can reach its roots in summer. A compost of limestone chippings, leaf-mould and sand will be found quite satisfactory. It is perfectly dwarf and compact in habit, making cushions of small rosettes of dull grey green leaves that feel clammy and sticky to the touch and which do not exceed an inch in height. From the base of the leaves its lovely blossoms appear, sitting tight on the plant. They are large and round and are a clear rosy pink colour. Alpine house conditions are extremely beneficial to its culture and can be well recommended.

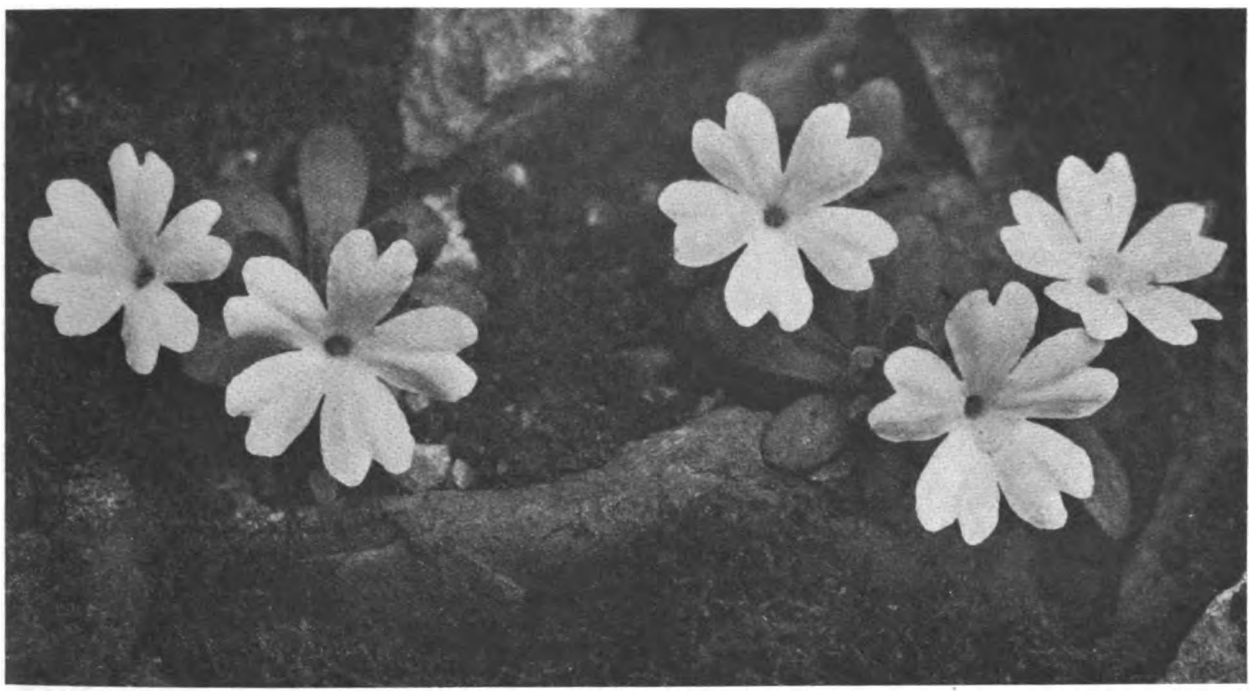
P. SPECTABILIS.—I have often read the praises bestowed upon this plant, but only to regret not having acquainted myself with its reputed beauty, although I have handled a good many and have had well established and thriving specimens. Only on odd occasions have I witnessed its flowers, which seemed only moderately good. It makes sturdy rosettes of stout dark green leaves and bears heads of bright pink flowers on 3in. stems. It is a limestone lover and requires ordinary good loam and a sunny position.

P. TYROLENSIS.—Hailing from the limestones of the Dolomites, we have this (closely allied to P. Allioni) species. Charming as it is, it cannot rival its near cousin. Small rosettes are formed of small, almost round leaves, which are covered with minute hairs and have a much serrated margin. As the plant ages the stems become long and are only furnished with old dried-up leaves, with the exception of the rosette of leaves at the tip. The flowers are borne singly on short stems and are large and bright pink. It will grow well in the moraine especially if it be wedged in a sunny crevice in a good gritty mixture where its roots can get well down. Alpine house conditions are also extremely satisfactory.

P. PEDEMONTANA is quite a charming little species, although not quite so attractive as some already mentioned, it is still worth including in a good collection. It is dwarf in habit, being but 2ins. or 3ins. high. The leaves are leathery with margins of short, dense, snuff-brown hairs, which are a feature of the plant. The flowers are carried in loose heads on slender stems and are of a rose shade. A well drained pocket or sunny ledge in the rock garden should fulfil its requirements.

P. GLAUCESCENS.—Perhaps this species is one of the commonest in rock gardens, which may partly be due to its easy cultivation. It will thrive and prosper in ordinary good loam in a sunny position, and makes tufts of shining glossy green leaves, quite dwarf and compact, from which ascend the dark coloured stems carrying its small heads of deep purple colour in April and May. It is a lime lover, and comes from the Italian Alps.

P. CARNICOLA.—A rare and choice species from the maritime Alps, where it frequents the mossy slopes in the shade of the pines. In cultivation, too, it is uncommon, but it is not difficult to grow in a cool, shady corner in a compost of leaf-mould and turfy loam. Its leaves are a bright green, very slightly hairy, and the flowers appear in heads on 4in. stems. They are large and round, of a delicate pink shade, marked with a distinct powdery white eye.



PRIMULA ALLIONII DELIGHTS IN A LIMESTONE CREVICE.

P. × BERNINÆ.—Conditions suitable to P. hirsuta apply also to this natural hybrid, between hirsuta and viscosa. From the former parent it takes its dense, low, tufted habit, with a taller flower-stalk of the latter. The flowers are deep pink, inclined to be purplish in fact, and are freely produced in May. It is rare in nature, even more so in cultivation.

P. AURICULA BAUHINI.—This form of P. auricula is no doubt very close to P. a. albo-marginata and P. a. albo-cincta; in fact, all three items may be regarded as the same plant from appearance. It is, however, a handsome plant, of easy culture, requiring very ordinary treatment. A cool situation in a good turfy loam should suffice to grow it well. The leaves, stout in texture, are wrapped in white meal, this being particularly heavy on their margins, giving the whole plant a most distinct appearance. Deep golden, white-eyed blossoms form heads on 3in. powdered, erect stems, and are heavily fragrant; these are at their best about May.

P. A. OLD RED DUSTY MILLER.—For more than a century has this fine old garden variety been in cultivation, but now its supply is scarce, except in one or two cases, where old-world plants are specially cared for. Outside the trade, old cottage gardens are the most likely places to find it and these are few and far between. Its large farina-covered leaves are always attractive, probably more so in the early days of spring when the tight winter buds unfold themselves. A mealy flowerstalk carries a head of quaint brick red blossoms 4ins. high in May. Cultural details as for the preceding item will be found satisfactory, and in cases where an alpine house is at hand specimens of these mealy auriculas should certainly be included where their beauty may be seen to the best advantage.

F. BARKER.

ABOUT GARDEN PAVING

A DESCRIPTIVE ARTICLE ON THE USE AND MISUSE OF GARDEN PAVING. THE MATERIALS USED IN GARDEN PAVING AND THE DESIGN TO BE FOLLOWED ARE USUALLY MATTERS OF CONSIDERABLE DIFFICULTY FOR THE ORDINARY GARDENER.

THERE seems to be a constant difference of opinion among garden owners as to whether garden paths should be paved, and one does meet, on the one hand, people who will have nothing but paved walks, and, on the other, those who have no use whatever for paving of any kind in the garden. Fashions come and go, and the prevailing fancy for ill-laid "crazy" paving is but too likely, in the end, to drive paving of every shape and form from the gardens of those who must always do what is "being done." That there *are* fashions in gardening none will deny, but, fortunately, the really keen gardener is above fashion's whims; he builds his garden to suit his personality and in the end, and if the personality is great enough, he may even set a fashion himself.

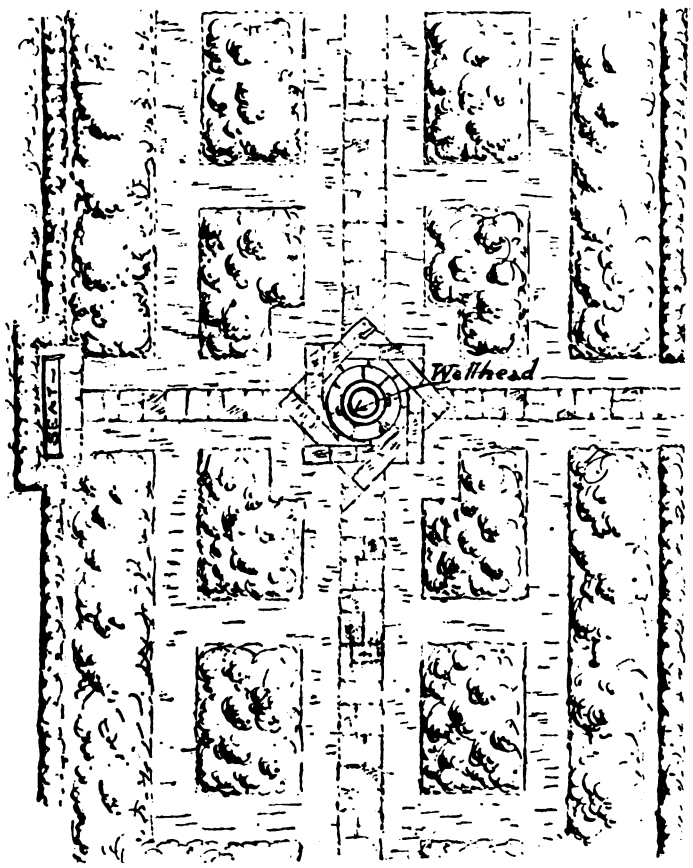

FIGURE 1.

The "personality" of a garden is a great thing, and there is something about even the faulty construction of a garden designed entirely by its plant-loving owner which makes a very real appeal to the hearts of other genuine garden lovers—an appeal which many professionally designed gardens, though infinitely better proportioned, fail to make. It is not easy for us garden architects to admit as much, but the fact has to be faced. It is only when the gardener himself has the gift of design, or when he has that appreciation of his own deficiencies which drives him to seek the collaboration of a designer that we get those outstanding gardens which give delight both to artist and plantsman.

We are in danger, however, of straying from our immediate topic. Let us look at this question of paving simply from the points of view of beauty and utility, leaving fashionable prejudice quite aside, and try to make up our minds where paving is desirable and where permissible, and under what circumstances it is entirely out of place.

From the point of view of utility, properly laid paving provides a dry way and enables one to admire a garden or to traverse it for any purpose dryshod, while the raindrops still hang on the foliage. "The dew that on the violet lies" can only be observed in comfort if we have a means of approach which will keep us dry under foot. So far, however, paving has no advantage over good gravel, and there are positions where, from the point of view of strict utility, it is decidedly inferior. Stone paving, in particular, withstands heavy traffic—particularly wheeled traffic—much worse than gravel, and there are places where, even from the standpoint of appearance, a firm-setting, nice-coloured gravel has superior attractions, warmth of colour being one of them. Brick paving is (or should be) warm in colour, but it cannot altogether supersede gravel, because it is only attractive when used in comparatively narrow strips or ribbons. A considerable stretch of brick paving is, however ingenious its arrangement, a paved yard and nothing more.

Mown greensward forms the best of all possible settings for dwarf roses and the generality of flowering shrubs and herbaceous plants, and no one with any sense of the fitness of things would let anything that might be called paving approach the wild or woodland garden. From the viewpoint of utility, however, turf will not withstand very hard wear, and it should not, as a rule, be used for paths in town gardens—at any rate not for through-paths which carry an appreciable amount of traffic. Wheeling materials over a turf walk in winter means the use of planks, or irreparable damage to the path. These drawbacks are, in addition to the fact that it holds moisture after rain and is, at some sesaons, scarcely ever free from dew. Turf may, however, be used as a setting and yet leave a dry, wear-resisting pathway, by running a strip of paving down the centre of a broad walk between the flowers (Fig. 1).

Herbaceous plants and dwarf shrubs with flowers in tones and tints of purple in any stage of dilution, as well as those with crimson, soft yellow, or cool pink flowers, or with silvery or silver-grey foliage suit well with the brownish or purplish grey of self-faced York paving, and the paving has, in this case, the additional advantage of allowing dwarf plants of prostrate or spreading growth to tumble gracefully upon it and display their charms without fear of their getting mud-splashed or weed-infested.

Where there is no space for a paved garden for plants such as these, or where the cost would be prohibitive, it is permissible to set out the usual grass walk and to edge for a couple of feet either side with the paving. Or the character of the garden may be modified somewhat, and cobble-stones (petrified kidneys), old bricks, crazy paving and what-not may be pressed into service to produce a Dutch-garden

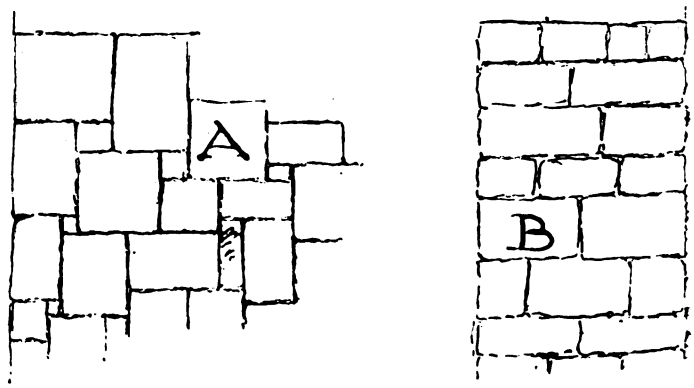

FIGURE 2.

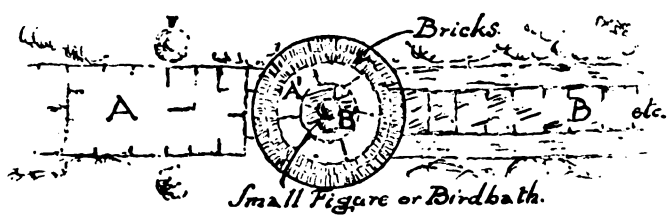

FIGURE 3

Digitized by Google

effect, but care should be taken to make adequate pathways for actual progress; cobble-stones are *not* comfortable to walk upon.

Squared paving is, as a rule, desirable for garden paths and terraces, but crazy paving, if carefully and closely jointed and well bedded, forms unexceptionable footways, which are only less effective than those composed of squared materials. Where extensive areas are to be covered it may often be used very effectively in conjunction with squared paving (or squared paving and bricks), and the effect is sometimes better than if all squared stone has been used.

In more or less formal places—under pergolas, in the open spaces of the paved garden, on important terraces, and so on—a certain amount of design in the paving is admissible or even desirable, but the fascination of those complexities must not tempt us to make our paving too elaborate. Unless on quite a small scale in a little Dutch winter-and-early-spring garden, very elaborate pavements bring back unpleasant

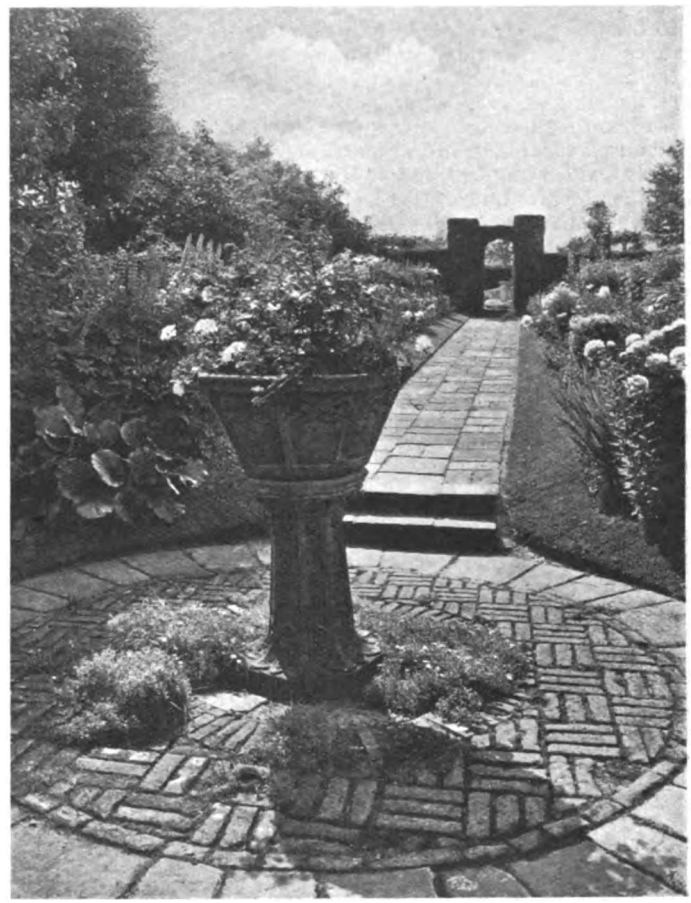
A PLEASANT COMBINATION OF BRICK AND TILE.

recollections of parterres in coloured earths and other barbarous and outdated styles.

Almost all stones other than York self-faced, which is laminated and splits pretty much like roofing slate, must be sawn to get a reasonably smooth tread. Such sawn pavings are to be obtained in various parts of Britain in brown, various greys, purplish blue and red. Self-faced York is certainly the most beautiful stone for garden paving, as it displays a beauty of texture quite impossible with any sawn stone. It is usually sold in 1½in. and 2in. thicknesses (approximate, of course), and care should be taken to order the whole of the stone required for a particular job at once, otherwise the two or more lots may vary greatly in colour and the total effect be anything but charming. For this reason it is sometimes wise, where a paved path is being laid down to join a stretch of paving already in existence to insert some little feature in the paving at or about the junction, introducing other materials to mark the dissimilarity Fig. 3).

Concrete is sometimes used for paving instead of stone. It is not a material to enthuse over, and should not be employed if stone comes within the range of practical politics, yet, if properly laid, it is hard wearing and, for positions where stone seems called for, better than gravel. People who must have impervious paths and cannot (or will not) afford stone, should certainly use it in preference to asphalt, which, in a garden, is an abomination. Bricks new or old of good red colouring and which will withstand frost when lying in damp earth form a good paving for narrow paths in old-fashioned gardens, and, in combination with other kinds of paving are useful in larger spaces. Roofing tiles on edge—otherwise useless old tiles from a crooked and dismantled roof will do—are often used as effective incidents in paving, and cobble-stones come in for the same purpose.

When squared stone is ordered from the quarry or agent, exact dimensions of the work should be given, with dimensioned drawings showing any patterning and instructions as to whether the stone is wanted in courses (" coursed random "), or otherwise (" random "). Fig. 2 shows the difference between the two



DOUBLE COURSED SELF FACED PAVING WITH GRASS EDGES.

styles. Crazy paving must, of course, be fitted and worked-up on the site.

Paving should always be laid on a layer of really fine material—sand or ashes, or lime—or cement mortar. Small paving, tiles, bricks, etc., should be set in mortar and the smaller pieces of crazy paving should certainly be bedded in mortar. It is in any case useless to lay paving direct on to ground which is liable to be flooded or to move when soddened. In bad cases a layer of concrete may be necessary as a foundation.

The question of paving is very much bound up with that of garden stairways and, where water is to be treated formally, with pond-edgings, and these three features should be considered together.

In certain positions the question of arrangement of paving should be given careful consideration. Care should be taken to avoid discrepancy of line when the general design is being laid out. In the case of laying out of paths such discrepancy of line is often noticeable, and it is afterwards realised that a different arrangement would have been preferable in the position.

R. V. G. WOOLLEY.

THE VALUE OF HUMUS

BY E. HANNAFORD RICHARDS,
Rothamsted Experimental Station.

ALTHOUGH the real nature of that important constituent of fertile soil, commonly known as "humus," is still the subject of discussion by agricultural chemists, there is no difference of opinion as to the value of organic matter in maintaining a high level of crop production. Whatever the scientific experts may say, the practical gardener knows this fact so well that it is quite unnecessary to go into the reasons here. In the present article it is proposed to deal with the different ways by which organic matter can be added to the soil, to discuss the advantages and disadvantages of each method and to show how the best value can be obtained in different circumstances.

First of all comes farmyard or stable manure, the oldest of all fertilisers, so aptly called by Kipling "the brown mother of all things." When this is of good quality it is the best of all ways of adding organic matter to the soil, since, besides providing the raw material of humus in the most suitable form, dung is also a "complete" manure. Its proportion of phosphate is low compared with nitrogen and potash, but this lack of balance is, of course, easily remedied by dressings of phosphatic manure. Unfortunately, much of the stable manure from towns is now very poor stuff, containing much rubbish of no fertilising value and, occasionally, oil waste and other things actually injurious to plant life. Further, dung often introduces weeds into a garden which were not previously found there. The greatest trouble about farmyard manure is that there is not nearly enough of it, and, consequently, it is expensive. The substitution of mechanical for horse traction has reduced the amount produced in towns, but even in purely agricultural areas it is not always easy for the gardener to get what he requires.

The farmer frequently gets over a shortage of organic matter in his soil by sowing a quick-growing crop, such as mustard, and ploughing this in when it has made a vigorous growth. The leaves and stems rot in the soil and so increase the supply of humus. There are several difficulties which limit this practice on farms, and these apply with even greater force to the smaller area of the garden, viz., the time required to grow the green crop and its dependence on suitable weather conditions to produce a satisfactory bulk. In spite of these objections, green manuring is used to some extent in gardens and most of the leading seedsmen supply special seed mixtures for this purpose. As will be explained later, the crop takes some time to decay after digging in, especially on the heavier soils, so that this method should not be used in cases where a short well rotted manure is known to give the best results with the following crop.

A third means of supplying organic matter is to buy in shoddy or one of the many prepared organic manures now on the market. Not all of these are of equal value, but there are several reliable brands which may be used with confidence. Manures of this class have the advantage of simple and easy application, but, as they must be used liberally if they are to have any physical effect on the soil, the cost, including carriage, becomes rather heavy.

Finally, we come to the preparation of synthetic or manufactured farmyard manure, by arranging a controlled fermentation or rotting of vegetable matter so as to produce an organic fertiliser having the virtues of farmyard manure without the few disadvantages referred to above. This method is at once the oldest and the newest of those employed by the experienced gardener; oldest, because from the earliest times a compost heap in which grass cuttings, leaves, etc., were allowed to rot down has been a feature of every well managed garden; newest, because it is only within the last two years that the complex biochemical changes associated with the decay of cellulosic matter have been explored to a stage which allows them to be controlled so as to yield a product superior in some respects to good farmyard manure. Every garden produces cellulosic material, the potential source of soil humus. Much of this is usually burnt, but it is obviously wasteful to destroy what nature provides gratuitously, and to buy in dung or organic manures until the waste vegetable matter on the spot has been used to the best advantage.

As a result of researches carried out at Rothamsted Experimental Station it is now known that the micro-organisms concerned in the breakdown of the carbohydrates, which constitute at least 80 per cent. of the dry weight of most plant tissues, can be stimulated by certain chemical compounds. Further, there is a definite quantitative relationship between the weight of chemicals required and the fermentation of a given weight of cellulosic matter. The term "cellulosic" includes all carbohydrates normally found in plant tissue, *i.e.*, sugars, pentosans, starches, besides the different varieties of cellulose. These are given in the order in which they are most easily fermented: sugars in a few hours; ligno-cellulose, or woody fibre, in its most resistant form, will require several months. Nitrogen is by far the most important element concerned in cellulosic fermentation. Some kinds of garden refuse contain sufficient nitrogen but are lacking in some other essential constituents, *e.g.*, phosphate. By suitably adjusting the proportions of different types of waste vegetable matter, it is theoretically possible to balance the foods required by the organisms. In practice a compromise must be made suitable to the average kinds of garden refuse.

There is one very important fact to be remembered. If the special requirements of the organisms concerned are not met by the supply of sufficient chemical stimulants in suitable form and, consequently, unfermented carbohydrate is dug into the soil, the microbes will draw on the reserves of plant food in the soil to complete the work not performed in the manure heap. As an example, if raw straw is dug into a fertile soil, the first crops taken will be less than those from untreated soil. Carefully controlled experiments on farm lands have shown that even a liberal application of complete artificial manures did not redress the balance. Of course, this effect is most pronounced with soils in poor condition, but it is always preferable to rot cellulosic material in the heap, until, at any rate, the sugars, pentosans and starches have disappeared, rather than to dig in the rubbish straight away, if a rapid turn-over of soil capital is desired.

Most of the knowledge briefly summarised above has been obtained in the course of study of the fermentation of animal manure, leading to the production of synthetic, or manufactured, farmyard manure from straw and other cellulosic materials. For more than eleven years, Lord Elveden has provided funds to maintain a research chemist at Rothamsted. Many of the early field trials, including the first successful production of synthetic manure from straw at a price comparable with farmyard manure, were carried out on Lord Elveden's estate at Pyrford, Surrey. These farm trials, and the whole of the elaborate series of experiments with garden refuse, were made by Mr. W. Auton, who has charge of the Pyrford Court gardens, and the successful outcome is very largely due to his skill and special knowledge. In 1921, when the laboratory work and small scale experiments had shown encouraging results, Lord Elveden formed a private company, originally known as Agricultural Developments Company (Pyrford), Limited, to carry the work to the commercial scale. This involved a heavy expenditure on staff and plant, which is outside the scope of a research institution. The capital of the company is provided by Lord Elveden, and any profit after payment of expenses will be devoted to further research on the lines which have proved so successful in the past.

The company (now known as Adco, Limited), owns the British and foreign patents for processes for preparing synthetic farmyard manure and for the special chemical reagents manufactured and sold by the company under its trade mark "Adco." These have been very widely used both at home and overseas for the treatment of a great variety of waste vegetable matter. Besides garden refuse of all kinds, straw, rushes, bracken and spoilt hay have been turned into manure during 1924. Overseas, the "Adco" process appears to have a future in tropical agriculture. "Adco" manure is now under trial in India,

Digitized by Google

Australia, Brazil, the Gold Coast and elsewhere, for the cultivation of tea, coffee, cocoa, sugar and bananas, to mention some of the more familiar crops. In Rhodesia both maize stalks and veldt grass have been made into very good manure which is now being tested against farmyard manure on potatoes.

For obvious reasons it is difficult to give definite figures for increases of crops grown in the ordinary garden. A plot trial made by Dr. F. Haviland, St. Leonards, with "Adco" manure made from bracken, showed increased yields from 5 to 20 per cent. greater than from corresponding plots dressed with equal quantities of dung. Messrs. Sutton and Sons made a careful test on their trial grounds at Reading last year with "Adco" manure made from straw, and have kindly given permission for their report to be published. Copies are available to any readers who are interested. In conclusion, it may be noted that while synthetic farmyard manure is not likely to be of interest to those gardeners who are fortunate enough to obtain ample supplies of stable manure at a cost of less than 10s. a load, nor to those who have to buy raw material in the form of straw at its present high price, the "Adco" method of dealing with garden rubbish that would otherwise be burnt, fills a place in the economy of the soil which is likely to prove of increasing value in the future.

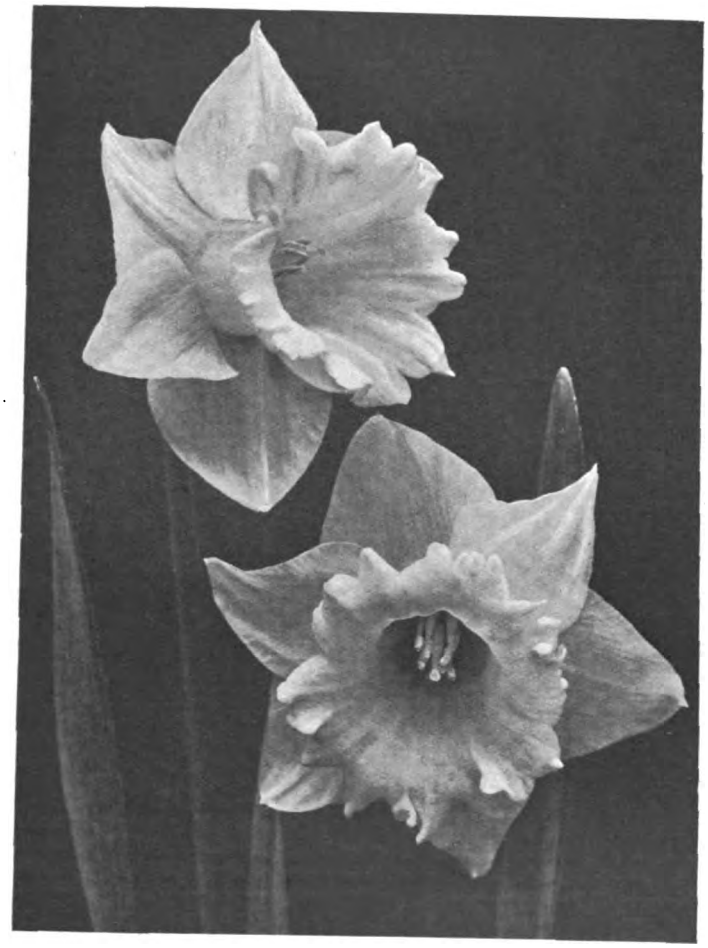
SPRING AT VINCENT SQUARE

ON the occasion of the fortnightly meeting of the Royal Horticultural Society at Vincent Square, Westminster, held on the 24th and 25th ult., the fact that Miss Spring had really and truly made her bow to 1925 was clearly manifest by the bright and gay appearance which met the eye on entering the hall. Alpines were present in large variety, while bulbs in the shape of narcissi and tulips, largely predominated. Carnations were also well to the fore, while orchids and greenhouse plants added their quota to the general effect of colour and fragrance.

One of the main features in the Show was the magnificent carpet of double tulips exhibited by Messrs. Sutton and Sons, Reading. The kaleidoscopic effect obtained by judicious planting of varieties with contrasting colours was truly wonderful. For bedding purposes these double tulips are excellent with their large flowers in all shades, borne on short, erect and rigid stems which are remarkably even in height. There can be no doubt, however, that the mere possession of double flowers detracts in some measure from their more extensive popularity. Such varieties as Mr. Van Tubergen, Hellenium (yellow), Lucretia, Peach Blossom, Apple Blossom, Orange Nassau, Lord Beaconsfield (pink) were all eminently displayed.

The stand of Mr. Elisha J. Hicks attracted considerable attention, which it well merited. The roses which were exhibited were truly wonderful productions considering the time of year. They all showed the result of clean and careful cultivation throughout the winter months, the foliage being in good condition, while the number of flowers and their colours were remarkable. Climbing Lady Hillingdon was the most prominent, and was closely followed by other varieties, such as Betty Uprichard, Mrs. Elisha Hicks (which is very fragrant), Mme. Butterfly, America and Rosa Moyesii, which was of a good colour for this time. Mr. Hicks is to be congratulated on the results he has attained under such trying climatic conditions.

Messrs. Bath, Limited, proved by their exhibit at the hall this week that they are capable of growing excellent Darwin and May-flowering tulips in bowls of fibre as well as the narcissi and hyacinths which were so much admired at the last two shows. The decorative value of bowls of tulips could be well appreciated from these well grown tall specimens of most entrancing colours. The carmines, scarlet crimsons and some of the yellows are particularly effective for indoor decoration. The well formed brilliant rose flowers of Pride of Haarlem, the shaded mauve of Feu Brilliant, Princess Elizabeth (light carmine) and Petrus Hondius (a rich rose) were some of the best. Long in stem and sturdy in growth was Bartigon, a fiery red tulip. There are no pure whites among the Darwins, but the nearest is White Queen, which Messrs. Bath were exhibiting. This variety is slightly shaded with mauve and is hardly worth growing when such beautiful varieties as Inglescombe Yellow (perfect in clearness and form), Suzon (a delicate buff rose almost white at the base) and Eclipse (a crimson) are obtainable. Zulu and Philip de Commines (both handsome purplish black tulips) and Bronze Queen formed a contrast to the other shades. All of these could be seen on Messrs. Bath's stand, and some of them should be added to next season's collection. The average grower when purchasing bulbs should consider the constitution as well as such points as colour, form and texture of the particular variety he contemplates buying. Certain varieties may appear perfect when exhibited, but in some cases they will be found to be not good doers. They produce poor weak growths, do not increase rapidly, and are not successful in all soils. One firm who realises the importance of constitution when raising new varieties is Messrs. J. R. Pearson and Sons, Limited. They were exhibiting again this week some of their own narcissi and a number of varieties introduced by other specialists. Among them were members of the white trumpet narcissi, giant Leedsii, jonquilla and poeticus sections. One of the outstanding varieties was Firetail, a large-flowered Barrii narcissus with creamy white broad segments and a flat reddish orange cup. Other good varieties were Capella (a pale giant Leedsii), Van Waveren's Giant (a large trumpet narcissus), Hon. Mrs. J. L. Francklin (a vigorous trumpet variety with upright stem), The Don (a pale bicolor daffodil), Ben Alder (a good yellow), Bernardino (a bicolor incomparabilis) and Princess Miriam.



NARCISSUS GODREVY, WHICH GAINED AN AWARD OF MERIT.

An excellent display of seedling narcissi under numbers and certain named varieties were again shown by Messrs. Barr and Sons. One looks forward to the time when these seedlings will be named and obtainable in commerce. Fantin Latour (a trumpet daffodil of great size with a lemon perianth and a deeper yellow trumpet), Sanda (a large jonquil hybrid of rich yellow), Watteau (of distinct colouring having its long narrow trumpet tinged with pink) were three of the named seedlings. Almost a self-colour daffodil was Princess Juliana, and White Nile, Crœsus and Mrs. Mackinnon are representative of the varieties exhibited by Messrs. Barr and Sons.

Messrs. Dobbie and Co., Limited, had a striking display consisting entirely of poetaz narcissi. All varieties of these were massed down one side of the hall. Poetaz narcissi are hybrids between the best forms of polyanthus narcissi and poeticus ornatus. They are all vigorous in growth and some carry as many as six flowers on each stem. These poetaz narcissi are equally suitable for growing in bowls or massing in borders. They are very sweetly scented and last for some days as cut flowers. Joconde was one of the best varieties, although not so large as some. It is a clear yellow with a golden yellow cup. Hæmon was of similar colour but a little deeper. The scarlet-edged cup added to

Digitized by Google

the attraction of the variety Admiration. A large white with a yellow cup was Alsace, and among the other varieties exhibited were Sovereign, Laurens Koster (a small flower almost white), Triumph, Irene (a yellow) and Grace Forbes (a pure white with a bright orange cup).

Another first-class exhibit of narcissi was that of Mr. J. Lionel Richardson of Waterford, Ireland, who had a good collection of well grown varieties. Although not one of the newest narcissi on this stand, the aptly named variety Sunrise was one of the most effective. The semi-transparent perianth is tinged with orange at the base, and the cup is of a rich orange red. Silvo, a pale giant trumpet, was also noticeable. The good qualities of Fantin Latour and Firetail were again impressed upon the public by this grower. Mr. Richardson was showing Golden Pedestal, a variety of his own raising and one of the finest incomparabilis on the market, being perfect in form and colour. The flowers are of exceptional size and of a beautiful golden yellow. Unfortunately, this variety is very rare and expensive. Glorious (a splendid poetaz narcissus), Empire and Queen of the North are three of the many good varieties exhibited by Mr. J. L. Richardson.

The alpines were, on the whole, more varied than at the last show. Mr. Mark Fenwick exhibited an interesting and diverse collection which included a very beautiful seedling of Narcissus triandrus, pure white with slightly reflexed petals and wide, crinkled cup; Tulip Kolpakovskiana; a delicate lilac-blue squill from Messina (Scilla Messinensis); the rare Primula Marven (Primula marginata × venusta), violet-purple with a white eye; the little pale yellow rhododendron R. flavidum; and a good bush of Daphne retusa, a stocky evergreen daphne from China with heads of large lilac-pink flowers which promises to be happier in cultivation than many of its family. It appeared in several other exhibits, and should prove a valuable shrub for the rock garden. All the plants were remarkably well grown. Broad pans of Saxifraga Faldonside were nearly hidden in almost morbid floriferousness by the great yellow blossoms, and even the uncertain Saxifraga Boydii (S. Burseriana × aretioides) was flowering heartily.

Mr. Clarence Elliott showed several rare and interesting plants on a series of terraces built up of grey limestone which showed off admirably the magenta fur of Saxifraga Griesbachii Wisley variety (more vigorous than the type and even more fantastic in the pose of its tilted rosettes) and the cherry red of Farrer's Saxifraga Myra. Primula Allionii, that rarity of the Maritime Alps, looked happy enough hiding its neat rosette with large pink flowers in spite of its reputation for difficulty. Another very attractive rarity was the diminutive Scots pine, Pinus beuvronensis, which is one of the few dwarf conifers that reproduces the forest form in miniature. With Cupressus obtusa tetragona minima a 3in. mound of mossy green shown by the raiser, Mr. W. H. Rogers of Southampton, and Daphne petræa it makes an admirable combination of minute shrubs for the miniature rock garden. Another unusual plant shown by Mr. Clarence Elliott was Dentaria polyphylla, a woodland crucifer with creamy yellow flowers and ferny leaves which has far more grace and distinction than most of its race.

Messrs. Tucker of Oxford showed several plants of Daphne retusa, a pan of Androsace pyrenaica (like lumps of grey-green rock studded with minute jasmine flowers), the large-flowered form of Ranunculus amplexicaulis (a statuesque beauty) and—very different from these high alpines—the old-fashioned double primrose, sanguinea plena, which is not in the least blood red but of a cheerful claret colour that goes very well with the old double white. With several other exhibitors they showed the graceful little Hyacinthus amethystinus, which also belies its name, for it is a clear Cambridge blue and rather like Muscari Heavenly Blue, with the bells open instead of closed and a lighter, airier design. It was probably named from dried specimens, which are apt to become purple with age and might be called "amethystine."

Among the other exhibitors were the following:

ANEMONES.—Messrs. Reamsbottom and Co. and R. Gill.

AZALEAS.—Messrs. R. G. Cuthbert.

CARNATIONS.—Messrs. Allwood Brothers, C. Engelmann, and Stuart Low and Co.

CINERARIAS.—Messrs. Sutton and Sons.

FORCED SHRUBS.—Messrs L. R. Russell.

FRUIT.—Messrs. Bunyard, and Westmacott and Co., Limited.

ORCHIDS.—Messrs. Sanders and Stuart Low and Co.

POLYANTHUS. — Messrs. Blackmore and Langdon, R. Gill, K. and E. Hopkins, G. A. Miller, Arthur Pratt and Sheppards.

RHODODENDRONS.—Messrs. R. Gill and Son and G. Reuthe.

ROSES.—Mr. George Prince.

SHRUBS AND ALPINES.—Messrs. Bakers, Carter Page, William Cutbush, M. Prichard, G. Reuthe, Skelton and Kirby, G. A. Miller, Waterers, and G. Whitelegg.

VIOLETS.—Mr. Baldwin Pinney.

NEW AND RARE PLANTS.

PRIMULA BUNTY.—This variety merited the considerable attention it evoked, since it may be regarded as a distinct break in colour in the primula genus. The flowers were from ⅞in. to 1in. across and varied in colour from dark blue to purple. In a few flowers the purple tinging was round the eye. The stems were short so that the flowers arising from close and compact rosettes of leaves sat fairly tight on the plant. Award of merit. Shown by Messrs. Bakers, Wolverhampton.

RHODODENDRON BERNARD GILL AND R. FIREBALL.—These two rhododendron hybrids appeared to be remarkably close both in colour and habit. The flowers in each case were borne in light and compact trusses close to the foliage. The leaves varied from 3–4ins. in length. Award of merit. Shown by Messrs. Gill and Son, Falmouth.

TULIP HELLENIUM.—A double-flowered variety with large flowers of a bright yellow in colour. When fully expanded the flowers measured 5–6ins. across. These were borne perfectly on stems which varied slightly in height from 14–16ins. For bedding purposes it should prove a good variety. Award of merit. Shown by Messrs. Sutton and Sons, Reading.

NARCISSUS WHITEHILL.—This is a trumpet variety with large flowers almost pale white in colour. The trumpet was prettily crisped at the edges. Award of merit by Narcissus Committee. Shown by Mr. J. L. Richardson, Prospect Gardens, Waterford.

N. ST. WINNOW.—This variety was a large trumpet daffodil with the flowers well carried on long stems. The perianth was pale white in colour and almost transparent. The trumpet was crisped at the edges.

N. MILKMAID.—A pretty Leedsii variety. The short white tinged with yellow trumpet was characteristically frilled. The segments were whitish yellow in colour.

N. DOMINICK.—A large yellow variety with wide open trumpet with frilled edges.

N. GODREVY.—A magnificent large yellow trumpet variety. The segments were of good substance and deep yellow in colour. The trumpet was crisped and frilled, and measured about 1¼ins. across.

N. DAMSON.—A variety with white to yellowish perianth which contrasted well with the scarlet to orange cup, which was crisped and frilled.

N. BODELLY.—This variety carried large flowers with white segments and yellow trumpets. The trumpets were rather rigid and stood boldly out from the surrounding perianth. The above six varieties were all exhibited by Mr. P. D. Williams, Lanarth, St. Keverne, and each gained an award of merit by the Narcissus Committee.

ORCHIDS.

ODONTIODA VISCOUNTESS FOLKESTONE (Odontioda Coronation × Odontoglossum l' Empereur).—Although this young seedling was flowering for the first time, and with only a single flower, it exhibited such promising characters that the Orchid Committee recommended a preliminary commendation. The flower is equal in size to some of the best odontoglossums, the segments are particularly well formed, of deep violet rose colour, the central areas with chocolate-coloured blotches, the elongated labellum rendered attractive by reason of the bright yellow spiny crest. One of the finest of the many hybrids that have been raised from Odontioda Coronation. Shown by Mr. R. Gerrish, Milford Manor, Salisbury.

In order to prevent confusion with another hybrid of similar name, the plant given an award of merit on February 24th as Lælio-Cattleya Sheila has had its name amended to Lælio-Cattleya Sheila Beddington.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

THE AMATEUR FLOWER SHOW

A FEW HINTS FOR INTENDING EXHIBITORS AT THE AMATEUR SHOW TO BE HELD BY THE ROYAL HORTICULTURAL SOCIETY ON JUNE 30 AND JULY 1.

FELLOWS of the Royal Horticultural Society and horticulturists generally will welcome the decision of the Council to hold a special show for amateurs at the Horticultural Hall, Vincent Square, at the end of June. The success of the venture will depend upon the support it receives.

A few notes on the various classes may be of interest to prospective exhibitors.

The rose rightly takes its place at the head of the schedule. The great army of rose enthusiasts should in itself be sufficient to guarantee the success of the rose classes, especially as the show comes right in the heart of the rose season. Where suitable varieties are grown and grown well, there is not a vast difference between the garden rose and the one good enough for show. If the idea should present itself that it may not be possible to get flowers large enough, it might be well to point out that it is quite possible to overdo size. Beyond a certain point, according to the variety, size may tend to coarseness, and would thus be less desirable than the bloom which is a little on the small side.

The first six classes are devoted to roses. The first two are for teas and hybrid teas, the third and fourth for ramblers, and the fifth and sixth for types other than those mentioned. In each class the blooms are to be shown in vases. Incidentally, I am not sorry there are no box classes. We shall thus, I hope, be spared the sight of the over-dressed rose, a common sight when shown in boxes. By exhibiting in vases the foliage plays a part which is almost lacking, of necessity, in box classes. One point suggests itself, those varieties with good long stems, granted equally good blooms, will at least more readily lend themselves for "setting-up" effectively, than the shorter stemmed ones.

At this date important factors which will lead to success are good healthy plants, growing in a satisfactory soil.

If the rose beds have not been given a dressing of lime for the last two years they should certainly be given a good sprinkling at once. Ground quick lime is best for strong loam and chalk for lighter soils. This is particularly necessary after the excessively wet winter.

As it is advisable to give a top-dressing of decayed manure immediately after pruning, no time should be lost in giving the lime as the two should not be given together. After an interval of a few weeks the top-dressing of farmyard manure should be given, together with a good sprinkling of bone meal, and lightly forked in.

Rose pruning, if not already completed, should be finished as soon as possible. To some extent the nature of the pruning will be governed by the variety and its condition at pruning time. For exhibition blooms fairly hard pruning is desirable. The growths should be shortened according to their strength, the smaller the shoot the harder should it be pruned. As new shoots develop, all weak ones should be removed, and every shoot retained should be considered capable of producing an exhibition flower. All lower buds except the terminal one must be carefully pinched off.

Records prove that we get, more often than not, very dry spells in May and early June. This is the most critical time for growth, and coincides with the ideal time for encouraging growth and bud development. Should it be dry, applications of clear water should be alternated with weak manure water made from cow or horse manure and soot. Even in a season of normal rainfall, two or three manurial waterings will almost certainly be beneficial. Stirring the surface soil must also be considered essential.

Roses for the rambler class, at the end of June will be obtained principally from the multifloras and the early-flowering Wichuraianas. It will be too early for the late-flowering Wichuraianas of what one might term the Dorothy Perkins type. Assuming that the plants are well established, that they have strong, well ripened shoots capable of producing good trusses of bloom, the main point will be to provide them with frequent weak manure waterings during May and June and to keep down pests.

Classes 6 and 7 are for roses other than tea, hybrid tea or rambler. Three blooms of each variety.

If it is intended, as it appears to be, to admit any type other than those mentioned, the wording is not good. Some delightful species, such as Moyesii and Hugonis or Penzance hybrids would not look their best staged as single blooms, and dwarf polyanthas would not be admissible. It would appear then that hybrid perpetuals and Pernetianas would be the best types to show. These would in themselves make a charming exhibit. It would be as well if the Society gave a definite ruling on this point before it is too late.

Classes 7 and 8, for delphiniums, should prove very popular.

It will be interesting to see whether the more recent novelties will surpass such grand varieties as Millicent Blackmore, Sir Douglas Haig, The Alake, Statuaire Rude, King of Delphiniums, Harry Smetham, Lamartin, Nettie and Rev. E. Lascelles. Prize-winning spikes will probably be obtained from plants which have been established a year. The first essential detail will be the restriction of growths to not more than three or four or even fewer to a plant. The weaker ones should be removed when the shoots are about 6ins. high. Staking, watering and feeding are other points which must on no account be neglected. Each shoot must be carefully supported by a bamboo cane placed in position early and tied as necessary. Hollow-stemmed plants like the delphiniums are great absorbers of water and this should be given in abundance during May and June if at all necessary, and an occasional weak liquid manure watering. In addition some bone meal lightly forked around the plants in early spring will be valuable. The effect of this and the waterings will be to add size to the blooms and length to stem, and possibly to intensify the colour of the flowers.

Classes 9, 10 and 11 are for sweet peas.

These will come as a preliminary to the National Sweet Pea Society's Show a fortnight later. Those who made an early start by sowing the seeds last October should have no difficulty in getting plenty of flowers by the end of June. Sowings made early in the year in gentle heat should also be ready. Planting should take place as early in April as climatic and soil conditions will allow. Deep digging is essential and the soil must be enriched with well rotted manure. Lime is of great importance too, and the sweet pea is also a lover of potash and should have it in some form. In the final preparation of the soil, artificial manures at the rate of 1 lb. of bone meal and 1 lb. of sulphate of potash may be given to every 20ft. run of row. The plants must have plenty of space, about a foot apart in a double row being usual. The weaker growers, such as the orange shades, should be allowed only one main shoot per plant, but the strong growing varieties can well support two or even three. Beyond one good watering to settle the soil it will be better to avoid this for some time, as it would only tend to keep the roots cold.

Dustings of soot may be necessary to ward off slugs. After a few weeks of apparent quietness, during which time the plants are rooting, if not making much growth, they will grow away rapidly if anything like genial weather prevails. Tying the shoots to their supports, pinching out all side growths and tendrils, confining the plants to the leading shoot only, will be work of almost daily importance. By the end of May the plants will have got well up the stakes and possibly have commenced to bloom. At this stage feeding should begin and can be given in the form of weak liquid manure waterings and soot. Cold water direct from taps should not be used owing to its chilling effect on the roots, and the danger of such a check must be avoided.

Sulphate of potash, ½ oz. to a gallon of water, may be given if the weather is very warm and trying to the plants, using this quantity to four plants. Under such conditions a mulching with short manure, lawn clippings or leaf-soil will help to conserve moisture. Blooms must be regularly gathered, or it may be decided to remove buds until wanted for show. Three weeks must be allowed for safety. If warm weather prevails, two weeks would be sufficient to allow, but such a risk should not be run. A good exhibition bloom should have a stem 12ins. to 15ins. long, with four well-coloured flowers, well placed on the stem.

Classes 12 and 13 are for gladioli.

It is fairly safe to say these fine flowers were never more popular than they are to-day. The charming primulinus hybrids are great favourites, especially for cutting. Whether they will play a big part in the above classes is, however, doubtful. Exhibitors will probably depend upon the larger-flowering types. The date of the show is a little early for gladioli, and it will be necessary to anticipate this and gain a month by starting the corms in pots and planting out later. Or they can, of course, be grown and flowered in pots. For planting out, potting should have been done as early in March as possible, and a fairly rich compost of loam, leaf-soil and decayed manure used. One corm will require a 5in. pot. The pots should now be in a cold frame, and watering should not be necessary till growth begins. Planting out may be done towards the end of April, by which time growth should be a foot high. Staking the spikes early is important. If the position is an exposed one some protection should be given just before blooms commence to open. Stirring the soil, keeping free from weeds, watering as necessary, and when flower spikes develop with some weak manure water, will constitute other cultural details.

ARTHUR J. COBB.

GARDENING OF THE MONTH

FLOWER GARDEN.

ANNUALS AND BIENNIALS.—Sow hardy kinds in open ground in reserve beds and mixed borders. Thin out as soon as ready. Prick out hardy annuals sown last month in reserve beds. Sow at end of the month half-hardy annuals which will not transplant. Sow seed of aquilegias, sweet williams and wallflowers on a warm border.

ANTIRRHINUMS AND PENTSTEMONS.—Plant out rooted cuttings which are now in cold frames.

CALCEOLARIAS.—Plant out at end of the month.

CHRYSANTHEMUMS, BORDER.—Plant out in firm rich soil.

GLADIOLI.—Plant in large clumps on rich, well drained soil.

GRASSES, ORNAMENTAL.—Sow seed now.

HERBACEOUS BORDERS.—Hoe, keep a watch for slugs. Place ashes round such plants as delphiniums. Fill up any gaps with annuals and biennials.

HOLLYHOCKS.—Prepare site by digging well. Plant out at end of the month.

NYMPHÆAS.—Plant now in baskets filled with turfy loam and leaf-soil.

PANSIES AND VIOLAS.—Plant out in permanent positions.

PYRETHRUMS. — Transplant single and double kinds now.

ROSES.—Prune Teas and Noisette roses. Finish pruning Hybrid Teas. Fork in a light dressing of manure. Mulch newly planted roses and roses on light hungry soils. Spray with nicotine wash to keep down aphis.

SWEET PEAS.—Plant out those in pots and boxes. Stake well before planting. Sow seed on prepared ground. Protect young plants from cutting winds with spruce branches. Tie up young growths and protect from slugs.

VIOLETS.—Break up old clumps after flowering. Plant out in lines on well dug ground. Water and syringe if weather warm. Plant out violet cuttings rooted in frames.

LAWNS.—Mow weekly. Weed, and apply lawn sand.

FRAMES.—Start another batch of bedding begonias. Propagate perennials by inserting basal cuttings in sandy compost in frames. Prick off annuals sown in frames last month.

HARDY FRUIT.

APPLES AND PEARS.—Spray with nicotine wash just before flowers open, and with lead arsenate when they have set, to keep down attacks of codlin moth, March moth and apple-blossom weevil. Guard against pear midge. Apply methylated spirit with stiff paint brush to portions attacked with American blight.

APRICOTS.—Spray with Katakilla or good insecticide. Protect when flowering.

BLACKBERRIES.—Train on trellis or fence.

BLACK CURRANTS.—Spray with soft soap solution and quassia extract to check big bud.

CHERRIES AND PLUMS.—Syringe with quassia extract to prevent an attack of aphis. Give a light dusting of lime.

GOOSEBERRIES.—Examine for caterpillars. Hand pick or spray. Do not use lead arsenate.

GRAFTING.—Proceed with operation when sap rising. Graft cherries and plums first. Examine grafts done in March, fill up any cracks with grafting wax.

PEACHES AND NECTARINES.—Protect when flowering. Disbud shoots gradually. Guard against aphis and peach-leaf blister.

RASPBERRIES.—Hoe the ground and give a good mulch of manure.

RED AND WHITE CURRANTS.—Spray with paraffin emulsion to keep down currant moth.

STRAWBERRIES.—Hoe the bed. Give a dressing of artificials and soot and then a mulch of manure.

WALL FRUIT—Protect from frost when in bloom. Syringe with insecticides after flowering, to keep down aphis. Water trees under copings.

VEGETABLES.

ASPARAGUS.—Prick over the beds. Give a light dressing of nitrate of soda and, later, salt and soot. Prepare and make new beds. Plant young crowns, cover immediately with 4ins. of soil. Sow seed in nursery beds.

ARTICHOKES, GLOBE.—Make new plantations on well trenched ground. Plant strong side suckers. Mulch with long litter when finished.

BEET.—Sow globe beet on warm border. Do not select ground which has been recently manured.

BROAD BEANS.—Make a final sowing. Draw up soil round young plants and support the growths. Plant out those now in boxes. Watch for slugs.

CABBAGE AND CAULIFLOWER.—Prick out early sowings and make another sowing.

CARROTS.—Dust young seedlings with soot early in the morning. Hoe regularly. Make another sowing after dressing the ground with soot and wood ashes. Thin seedlings early.

FRENCH BEANS.—Sow a batch at the end of the month, and sow at the beginning of the month in frames.

HERBS.—Sow annual kinds. Divide and replant perennials.

LETTUCE.—Make sowings every fortnight and thin early, and transplant.

LEEKS AND ONIONS.—Plant out those raised in heat after hardening off, select mild showery weather for the operation. Sow main crop.

PEAS.—Plant out soon those in boxes. Stake seedlings soon. Make sowings every fourteen days. Sow main-crop marrowfats.

POTATOES.—Finish planting. Protect early varieties as soon as they are through the ground by drawing up soil round the shoots.

SEAKALE.—Plant out root cuttings. When well started reduce growths to one strong one to form a good crown.

SEED SOWING.—Make sowings of Brussels sprouts, rad shes, turnips, savoys, kohl-rabi, kale, parsley, New Zealand spinach, spinach and scorzonera. Thin seedlings as soon as they are fit to handle, and hoe frequently between the lines. Sow cardoons and celeriac in a frame.

SHALLOTS.—Plant on good ground.

FRAMES.—Ventilate well carrots, lettuce, etc.

SHRUBS.

PRUNING.—Clip ivy on houses and walls. Prune Buddleia Veitchiana, Ceanothus Gloire de Versailles and Hydrangea paniculata, if not already done.

GENERAL. — Hoe ground round newly planted trees and give them a light mulch. Rake and tidy shrubberies. Examine stakes and supports of shrubs.

ROCK GARDEN.

GENERAL.—Pick off all dead leaves and flowers. Restrict large clumps of arabis, aubrietia, cerastium, vinca, etc. Lightly stir the soil in between the plants. Plant out alpines now in frames. Finish top-dressing.

ANNUALS.—Make sowings in patches.

FLOWERS UNDER GLASS.

ABUTILON EUPATORIUM, ETC.—Re-pot old plants. Propagate by cuttings abutilon, cytisus, etc.

ANNUALS.—Stake and tie pot plants. Prick off seedlings for flowering outside, place in frames at end of the month.

BEDDING PLANTS.—Pot off seedling begonias, petunias, verbenas, etc. Shift all possible kinds into frames at end of April, and allow them to harden before planting outside. Remove specimen plants to cooler quarters.

BEGONIAS.—Pot up tuberous kinds as they start into growth.

CAMELLIAS.—Re-pot those which have not sufficient root room. Give weekly applications of liquid manure to young plants.

CANNAS.—Pot up as they start into growth; use 5in. pots.

CHRYSANTHEMUMS.—Re-pot and, later, pinch the points.

DAHLIAS.—Place pots in frames at the end of April to harden.

FORCED SHRUBS.—Prune deutzias, prunus, lilacs, etc., after flowering, and plant outside in a rich border. Prune forsythia.

FUCHSIAS.—Pinch when growing well, but not at the time of potting.

GREVILLEA ROBUSTA.—Pot up seedlings.

IVY GERANIUMS.—Re-pot now.

LILIUM AURATUM AND L. SPECIOSUM.—Bring from the frames into house. Do not give too high a temperature.

PERPETUAL CARNATIONS.—Pot late-struck plants into 6in. pots.

PRIMULAS AND CINERARIAS.—Sow seed in well drained pans.

ZONAL PELARGONIUMS.—Give another potting, and press soil very firmly.

GENERAL.—Give less heat as the days become warmer. Ventilate well, but guard against cold draughts. Prick off young seedlings and place on airy shelf near the glass. Harden off gradually plants which are to flower outside. Shade some plants if the sun is strong at the end of the month. Fumigate to keep down aphis.

FRUITS AND VEGETABLES UNDER GLASS.

APRICOTS.—Disbud before the shoots are too long. Remove those on underside and back. Leave well placed extension shoots. Attend to watering and feeding.

FIGS.—Pinch out all weak growths. Pinch back laterals to four or five leaves. Water frequently and syringe twice daily.

ORCHARD HOUSE.—Pollinate the flowers. Give drier conditions when in bloom. Ventilate well, but avoid cold draughts. Fumigate when fruit has set and syringe twice a day.

MELONS.—Pollinate and maintain a drier atmosphere when fruit setting. Pinch out point one leaf beyond the fruit. Continue pinching, stopping and tying for more advanced plants. Start damping and syringing again when fruit has set. Water regularly and very carefully; do not allow any water to touch the stems of the plant.

PEACHES AND NECTARINES.—Disbud shoots and thin fruit. Do the work gradually. First remove ill placed and misshapen fruit and, later, any extra fruit. Give more air to peaches when stoning. Syringe forcibly to keep down red spider. If attacked, spray with liver of sulphur. Fumigate with nicotine to keep down aphis. Water whenever necessary and feed at intervals with liquid manure or Thomson's manure. Feed occasionally with guano.

VINES. — Continue stopping laterals and tying. Thin grapes gradually; do not handle bunch. After thinning, dress the borders with vine manure. Give higher temperature when muscats in bloom.

CUCUMBERS.—Tie up and stop growths. Syringe and damp down. Keep temperature high, ventilate very carefully.

DWARF BEANS —Sow in boxes to form a succession.

MARROWS.—Make another sowing. Plant out young plants on a hot-bed.

MUSHROOMS.—Keep house moist and, if heated, lower the temperature. Prepare manure for beds outside.

SIMPLE GARDENING

ANTIRRHINUMS.

IT is possible to have blooms of these plants available ten months out of the year with the aid of a greenhouse and if the right varieties are grown. But the great majority of cultivators are satisfied if they obtain a nice display during the summer months. There are many lovers of these charming flowers who do not fully understand their treatment, and these notes may be helpful to such. The seeds should be sown in a frame or greenhouse during February. At this date all resultant seedlings should be about ½in. high and possessing four small rough leaves. Readers who wish to purchase young plants from firms advertising in THE GARDEN should order them to be sent out early in May, then they can be kept on a bed of ashes in a sheltered position till early in June, when the general bedding-out work is done. The young plants, during May, will become gradually hardened, and this should be the treatment of home-raised stock. From March to May the tiny seedlings should be transplanted, either in boxes, or beds in frames, 3ins. apart each way. Antirrhinums thrive in a medium-light compost in which some old mortar rubble has been mixed. Frame treatment is suitable and ensures stocky plants with judicious ventilation. The plants thrive in well drained soil and often fail in very wet ground. There are many lovely distinct colours which will please everyone, but the pink-flowered variety Nelrose should be included as it flowers a long time.

SOWING GRASS SEEDS.

In some gardens it is necessary to sow a few grass seeds every year in spring or early autumn, because certain lawns become patchy owing to character of soil or situation. Then, of course, there are the small lawns to be constructed either from seeds or turves. The latter are not always available; the seeds are, and if the owner will take the trouble thoroughly to free the soil from the roots of coarse weeds, he may soon possess a perfect lawn as our seed firms now take great care in the preparation of their lawn grass seeds. Few lawns are quite level; large, undulating ones are charming; even medium-sized ones may be so made on a modified scale, but the quite small affair should be level, or nearly so. In the case of clayey subsoils the surface should be 3ins. lower at one side or end, then water will not lodge on it. The soil should be well broken on the surface, raked and firmed while in a fairly dry state. Having done this work, very lightly mark out 1yd. squares, and then sow the seeds pretty thickly, finishing one square before sowing seeds on another. In this way the whole lawn space will be evenly sown. It will not be difficult to procure sufficient fine soil just to cover the seeds on a small area, but on larger ones the seeds should be neatly raked in. In all cases some immediate rolling will be beneficial, and a few strands of black cotton stretched across will keep off birds.

DAHLIAS FROM CUTTINGS.

All tubers of dahlias that were placed in boxes or on stages and partly buried in a light compost several weeks ago will now furnish nice slips suitable for cuttings. The amateur may succeed with the cuttings either in a propagating frame or in a frame on a hot-bed. Of course, there is, during the first three or four weeks after construction, a constant dampness in the frame arising from the fermenting material and as the stems of the cuttings are very soft and fleshy, care must be taken to prevent loss through damping-off. Always leave a small opening at the top of the frame, then the rank steam will escape. From strong cuttings very sturdy plants may be grown, and these will bear excellent flowers. The cuttings root in three weeks

time and so there is every opportunity to grow them on in pots or boxes in a cold frame and have strong specimens to plant out early in June. I like to propagate several cuttings in a small pot, inserting them round the sides as shown in the sketch. The best compost is one made of loam and leaf-soil in equal proportions and plenty of coarse sand. The letter *a* shows the old stem; *b*, old tuber; *c* and *d* show where to cut off the stem below a joint and the two leaves; *e*, sand on the surface; *f*, sand at the base of the cutting; and *g*, the depth to plunge the pot in the bed. Very careful watering is necessary.

TRANSPLANTING ONIONS AND LEEKS.

Small onion bulbs and rather thin leeks result when the seeds are sown in the open border late in March and during the first half of April. The small onions keep well when harvested and stored, but many cultivators like to grow some big specimens and such can only be obtained by sowing seeds under glass early in the year and transplanting the resultant seedlings. Now, having cared for the latter during their early stages of growth, it is essential for success that very careful treatment be the rule when transplanting the young onions and leeks in their final quarters. Rich, firm ground is necessary, but the firmness must not be obtained by treading or rolling the soil while it is rather moist. Indeed, I do not advocate treading except in the case of very light soil, and the surface portion, even then, should be quite dry. Heavier soils will be firmed by the treading necessary when preparing them for the young plants. I am presuming that the soil has been well manured at digging time. If not, in the case of leeks, trenches quite 2ft. deep and 18ins. wide should be opened and rotted manure freely mixed with the soil as two-thirds of it is replaced. The trench will accommodate two rows of plants at 1ft. to 16ins. apart. The surface of the soil for the onions should be made black with soot, the latter lightly forked in and the onions planted 9ins. apart in rows 14ins. asunder. Every bit of fleshy root should be retained and planted straight down with the aid of a hand trowel. Only the roots should be buried.

VENTILATION OF HOUSES.

During the spring months the correct ventilation of glass houses and frames is a very important matter. There is abundance of tender foliage now under glass. Outside, we often feel the cold, chilling east winds and do not like them. The young shoots, if unduly exposed to them, are checked and become, in some instances, stunted; then another evil befalls them—attacks by aphides, which live on their juices. If our greenhouses, fruit houses and frames are to be ventilated in a proper way, we must watch the weather conditions practically day and night. When cold winds prevail and, at the same time, the sun is very hot, it would be a mistake to keep a glass structure quite closed till, perhaps, the middle of the forenoon and then suddenly open wide the ventilators to lower the temperature, which may be approaching 100° Fahr. If, through unforeseen circumstances, houses are closed in this way, the ventilators should be opened a little only, and so that a cold current of air will not be admitted. A sprinkling of water on the floor will help matters, and the house should be closed early in the afternoon. Early in the morning admit a little air, and gradually increase it according to outside conditions. Where possible, in the case of frames as well as houses, admit air on the side opposite to that on which the wind blows. Cold draughts soon cause mildew on young vine and rose foliage under glass and should be guarded against. GEORGE GARNER.

CORRESPONDENCE

BLACK SPOT ON ROSES.

SIR,—As the outcome of a short article which appeared in THE GARDEN a few months ago regarding a remedy and palliative for that troublesome rose disease known as black spot, I have had many letters of enquiry as to the nature and strength of the mixture and manner of application. The preparation itself which we had found successful is a proprietary liquid called "Tarbol" (manufactured by The Chemical Union, Limited, Ipswich). At Oxted we find that satisfactory results are obtained when mixed and used in the following manner: A solution is prepared in the proportions of two tablespoonfuls of "Tarbol" to a three-gallon can of water. Immediately any signs of black spot make their appearance, as noted by the discoloration of the leaves, the plants are sprayed twice a week. If it is found that the disease has attacked the bed as a whole, the soil is drenched several times during the winter months, right up to pruning time, and so long as there is no new growth on the foliage a slightly stronger solution can be used with safety and advantage. Where the question of such a troublesome and spreading disease as black spot, or, indeed, any similar complaint, is likely to affect the life and growth of a rose, we act upon and thoroughly believe in the principle that "Prevention is better than cure."—HERBERT L. WETTERN, *Oxted*.

IRIS TINGITANA.

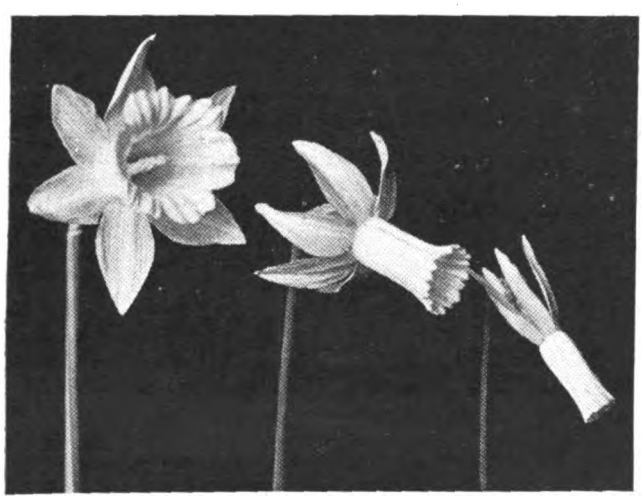
SIR,—Perhaps my experience in growing Iris tingitana may be of interest to your readers. I obtained the bulbs from Messrs. Wallace of Tunbridge Wells, and at the end of October potted them in fibre without drainage and kept them in an unheated cellar till they had made a good start, then removed them to the windowsill of a room facing due south but having no artificial heat. This treatment suited them very well, and they made rapid growth. As soon as the buds were well advanced I transferred them to a sunny room having the additional heat of a fire, and by Christmas they were in full bloom with strong stalks and good foliage. I believe they could have been grown entirely without fire heat had they been potted a month or six weeks earlier.—W. CHAMBERS.

LIMESTONE SOILS.

SIR,—In the various discussions on plants which thrive or do not thrive on limestone soils there is one point which I have not yet seen referred to, namely, the depth of the soil. I suggest that in this point may perhaps lie an explanation of some of the anomalies which have puzzled us. My own garden is upon the greensand with a depth of a good 10ft. of sandy loam. On this soil I can grow ericaceous plants and rhododendrons, if plenty of water is given. A few hundred feet away, where the soil is only 2ft. or 3ft. deep before the rock is reached, this would be impossible. It seems, therefore, very probable that all the lime has been washed out of this deep soil, and as we are now told that rain, having passed through the first few feet of soil, never returns, there would be no danger of the lime being brought up from below.—E. A. BUNYARD, *Maidstone*.

MINIATURE DAFFODILS.

SIR,—After reading the article on miniature daffodils by Mr. Edward Cahen in THE Garden for March 14th, with its suggestions for hybridising these charming little flowers, I feel sure your readers will be interested in seeing the enclosed photograph, which shows rather clearly what can be done by crossing a yellow trumpet with pollen of Narcissus cyclamineus. I took this photograph seventeen years ago. I have since then crossed yellow trumpet daffodils with the pollen from a seedling from N. Emperor crossed with N. cyclamineus, and have again crossed yellow trumpets with pollen from seedlings resulting from this secondary cross, and have had as a result glorious deep waxy yellow flowers as large as Emperor with scarcely any reflex in the petals and, curiously enough, I can almost always identify these seedlings by the little creamy tip to the perianth segments. In my experience these seedlings have not got good constitutions, and I am afraid it would be found that this is the drawback with all hybrids of these miniature varieties. I have found only a small percentage of triandrus hybrids are satisfactory in this respect. Trumpets crossed with bulbocodium in my experience produce the most appalling atrocities. Minimus and cyclamineus will intercross, and I have a delightful natural hybrid between these two which appeared in a grassy bank where its two parents had been naturalised for some years.—W. A. WATTS, *St. Asaph*.



N. OBVALLARIS. HYBRID. N. CYCLAMINEUS.

SEEDS AND SEED LISTS.

SIR,—One sentence in Mr. Eric F. Wettern's letter prompts me to put pen to paper in defence of British seedsmen. Mr. Wettern says: "It has always been a mystery to me why there is apparently no English firm sufficiently enterprising to cater for this branch of horticulture." The branch referred to is stocking and cataloguing seeds of trees and shrubs. The reason why is simply the smallness and uncertainty of the demand. There are some enthusiasts, like Mr. Wettern, who "indulge in the fascinating pastime of tree and shrub propagation," but they constitute a small circle, usually well acquainted with each other and mutually interested in their pursuit. One sows seeds of certain shrubs, another some other kinds, and each has some surplus seedlings which, naturally enough, will be passed on to friends rather than wasted. That is quite an agreeable arrangement for the amateur, but the seedsman, in order to supply a customer with a half-crown packet of some particular shrub's seeds, sends abroad for enough seeds for at least a dozen packets. These are packeted, catalogued, put into stock, in all probability to remain there, and the seedsman finds it works out that in purchase, correspondence, postage, packeting and cataloguing he has spent a pound and received 2s. 6d. Meanwhile he has sold sacks of peas and pecks of onion, carrot and radish seed because they are in general demand, and the practice of exchanging and giving is less prevalent among the masses than among the few specialists.

That the foreign seedsman can always supply seeds of trees and shrubs is no indication of greater enterprise, but simply that he is the wholesaler of these particular lines, and can always fill an odd order without specially providing for it. If Mr. Wettern can persuade a few thousand amateurs to buy seeds of trees and shrubs, the British seedsman will show no lack of enterprise in this direction, but I have in my time helped to burn the seeds that were stocked in readiness for orders which failed to come after circulation of a very good catalogue.—A. J. M.

SEQUOIA GIGANTEA.

SIR,—Perhaps you would like to add to your sequoia records the following: Planted 1856, at Hatch Beauchamp, Somersetshire; height in 1863, 11ft. 6ins.; the growth in 1862 was 21ins. Planted 1859, at Rev. J. Gould's, Burwash, Sussex; 1863, April, height 5ft. 10ins. The same diary notes Araucaria imbricata and Cedrus Deodara, planted 1841, and states that in 1860 the Araucaria was 26ft. high and the Cedrus Deodara 28ft. I wonder if any of the above survive.—GEO. DILLISTONE.

SLUGS IN THE GARDEN.

SIR,—In reply to your correspondent "Formakin" *re* slugs, I quite agree that my statement that 15,000 slugs per day were killed last season in our kitchen garden may sound comical or all but incredible to anyone who did not see the pests or was not responsible for the supply of flowers or vegetables from the garden these pests had invaded, but I can assure "Formakin" my feelings changed from comical to desperate when confronted with such a serious menace. Does "Formakin" think it possible for anyone to pick eighty-seven slugs off one delphinium shoot not more than 9ins. high in the evening and secure fifty-four off the remains of the shoot next morning? The stool of the delphinium had previously been well "ringed" with Vaporite as a "protection." There was nothing comical from my point of view in planting over 3,000 onions on the Monday and looking on bare ground on Wednesday. Six rows each 58yds. long yielded fewer than a dozen parsnips, and double the number of onions resulted in nothing. One row of parsley over 60yds. long took me over an hour night and morning to clear of slugs, the "bag" in each case never being much below 1,000. I do not think any edging would have done me any good, as I found quantities of slugs up the peasticks, and plenty climbed up the gooseberry bushes and fed off the leaves. I am blest with a good edging in the flower garden in the form of miles of box edging, and in addition huge beech hedges, several yew hedges. In my efforts to destroy the slugs I used 40 bushels of soot, 1 ton of slacked lime, 2cwt. of slug destroyer, 2cwt. of Vaporite, 2cwt. of Terrafumite and various washes.—F. C. KING.

A FEW NAMES

FOR my own edification, I have lately been looking up the origin of some of the weird names that are tacked on to plants coming from eastern Asia. As these names may be puzzling to readers of THE GARDEN, I give a few origins which are derivative from foreign explorers in the East.

Albrechtii (Rhododendron Albrechtii).—Dr. Albrecht, a Russian Naval surgeon, born in 1821, spent six years in Hakodate in Japan, where he made large collections.

Bungeana (Pinus Bungeana).—Dr. Alexander von Bunge, an eminent Russian botanist, born in 1805, was sent to Pekin as a botanist in 1830. He collected extensively in the Peking plain until he quarrelled with the Chinese authorities, who forbade him to go outside the walls of the city.

Davidi (Acer Davidi).—The Abbé David, the earliest of the three great French missionaries to whom we owe so many of our Chinese plants. He joined the Mission of the Lazarists in Pekin in 1862. He made three notable journeys, the first in 1866 to southern Mongolia; the second, 1868–70, in central China and eastern Tibet; the third, from 1872–74, through Chili, Honan, Shansi and Kansu. All these three journeys were north of the Yangtze.

Decaisnea (Decaisnea Fargesii).—Decaisne was a skilled Belgian horticulturist born in 1809, after whom J. D. Hooker called a new genus.

Delavayi (Magnolia Delavayi).—Père Delavay arrived in China in 1867. Collected in Hupeh, Szechuan and Yunnan, but principally in the latter. M. Franchet recounts how he received specimens of over 4,000 species from this indefatigable botanist.

Desfontainea (Desfontainea spinosa). — 1750–1833. Desfontains, Professor of Botany of the Royal Garden, Paris. A new genus was called after him in 1794.

Fargesii (Rhododendron Fargesii). — Père Farges, a French missionary who collected in north-eastern Szechuan and in Shansi from 1892 onwards.

Maackia (Maackia amurensis).—Maack, Professor of Natural Sciences at Irkutsk in 1852. Travelled widely in Eastern Siberia.

Maximowiczii (Primula Maximowiczii).—Dr. Carl Maximowicz. The most prominent botanist that Russia has produced, born in 1827. Travelled in Mongolia, Manchuria and Japan.

Potanini (Rhus Potanini).—Grigori Nicolaevitch Potanin, one of the most eminent of all Russian travellers. Made four great journeys in Mongolia and north-western China and Tibet from 1876 to 1894. In early life he became head of a curious Siberian conspiracy which aimed at setting up Siberia as a separate kingdom. For this he spent six years as a convict. Probably his best known introduction was Rheum Alexandræ, called after his wife.

Schlippenbachii (Rhododendron Schlippenbachii). — Called after Schlippenbach, a Russian naval officer whose only claim to fame is that this fine rhododendron was called after him. A rhododendron by any other name was just as sweet.

Thunbergii (Berberis Thunbergii).—Thunberg was a famous Swedish Professor of Botany, who lived from 1743–1822 and wrote the "Flora Japonica."

Weyrichii (Rhododendron Weyrichii).—Dr. Weyrich, a medical officer in the Russian navy in the middle of the last century. He botanised in the Far East wherever his boat took him.

One other name that bothered me was "tangutica," which is the specific name of several well known plants, among them Clematis tangutica. As far as I can make out, the Tanguts is an old name for a tribe which either inhabits or used to inhabit that undefined corner where Tibet joins China on the one side and Mongolia on the other.

I have left out a few names, like Przewalski, when the plants called after them are very uncommon. Some of those names are almost human, but I feel better about even the worst of them now that I have found out that those whose names they were supposed to perpetuate actually lived at some time or another.

FRAGRANCE in the SPRING GARDEN

IN THIS ARTICLE THE AUTHOR DESCRIBES A FEW PLANTS WHICH SHOULD BE INCLUDED IN ALL GARDENS FOR THE SAKE OF THEIR FRAGRANCE DURING THE SPRING MONTHS.

FRAGRANCE—that sweet, subtle, indefinable grace—is necessary throughout the whole of the garden if it is to live and linger in the memory as a place of beauty and charm. And, in writing "throughout," we make no exceptions whatever. In the kitchen garden we demand our fragrant herbs—our lavender and lemon thyme. In the shrubbery, our delicate bay, daphne and other sweets. In the rose garden, our sweet briar and perfumed roses—and so the story goes on through every bed and border, a complete chain of separate, distinct—sometimes blended—but never competing scents.

Fragrance in some directions is in danger of becoming lost, and it is up to some of us to see that this precious heritage from the past is not lightly cast aside for mere size or colour or other beauties that please the eye but fail to make the slightest appeal of scent. This is the case with far too many of our popular modern varieties of the rose and the sweet pea, while Nature herself, possibly in a fit of pique or as a punishment, has withdrawn the perfume from the musk, which used to run almost as a wilding in the memory garden of our childhood's days.

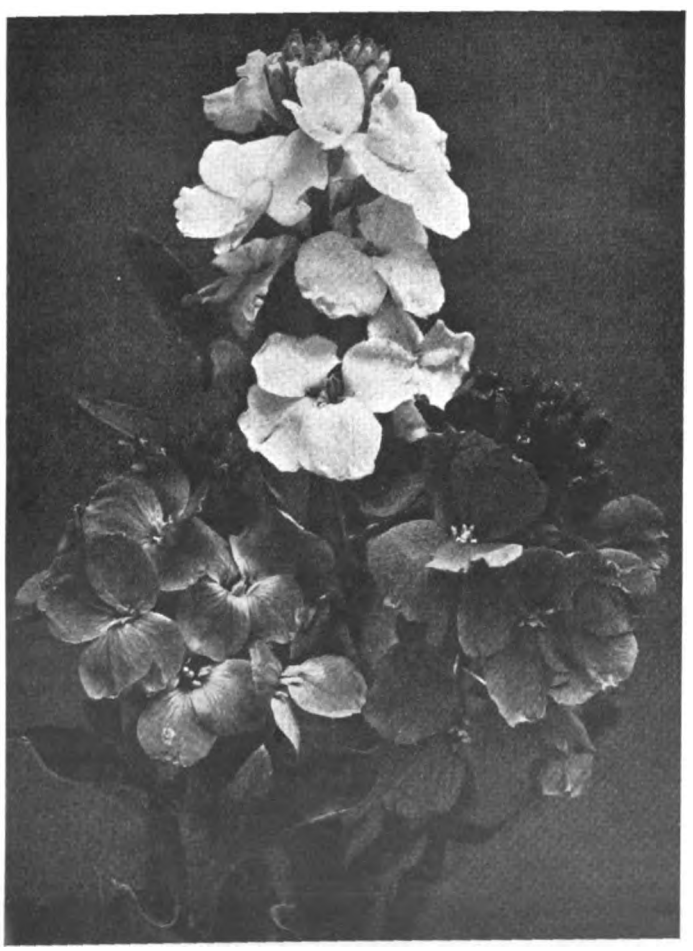
Especially do we demand fragrance in the evening garden, when in the grateful coolness of the dusk we wander once more along the flowery paths to drink in great wafts of the perfume of the old time white jasmine, the tobacco flower and the all-penetrating and all-pervading night-scented stock. The latter is a wonder, and a broad breadth of it sown near the room that is chiefly occupied during the evening is a delight, both indoors and out, for many months. Nothing could be simpler than this, for all one has to do is to rake over the surface soil in early April, scatter the seed thinly, gently pat the soil, and we shall soon have a bountiful crop of tiny seedlings that give so poor an impression of their future possibilities. The capacity is there, however, and those slender-looking plants are going to branch and branch until not a speck of bare ground is visible and the tops are literally smothered with a tangle

THE SPRING SNOWFLAKE, LEUCOJUM VERNUM, LOOKS WELL IN CLUMPS.

of the tiny starry pinkish purple flowers that advertise their presence over the whole garden. Another, less powerful, but by no means to be despised, evening perfume comes from the evening primrose that so regularly expands its huge primrose flowers each evening by taking off the pointed cap and unrolling the closely packed petals. Among the many day-scented flowers that become more odorous at night may be mentioned the lilies, and especially those later-flowering forms auratum and speciosum. These are indeed only open air flowers, for, if one cuts and brings them within doors, the perfume soon becomes so powerful as to be unpleasant.

Let us, however, be systematic and not drift into generalities. Spring, opening its welcome to the year of flowers, is a very important time and, happily, bulbous and other flowers may be found in plenty that will add their quota of perfume to the rapidly accumulating treasures that are expanding upon all hands. Many of these are old-world plants, too, that thereby add an extra charm to the scene. Are there not the jonquils, most fragrant of the smaller narcissi; the poeticus and double white, again both full of delightful perfume, and no less attractive from the floral point of view? Equally valuable and considerably earlier is the hyacinth, a flower that loses all its stiffness when brought into the house and skilfully arranged with sufficient suitable foliage. The colour range is so wide and varied, too, that kinds may be chosen that will "fit in" with any possible scheme of colour decoration. Wallflowers are a host in themselves, and I have yet to meet the person who did not at once fall a victim to their charms and sniff—and sniff again—at the delicious odour that seems to typify all that is best in a real spring day. Plant these generously in broad sweeps and drifts, not in niggling little beds, and you will gain in every way, for not only will the garden be a blaze of rich satisfying colour and fragrance, alive with humming bees, but there will be no lack of the best possible material for the vases and to give away.

Among the earliest fragrant flowers of spring comes the Daphne Mezereum, to find which we must visit the shrubbery. Here, in a protected spot before January has passed, it is often possible to cut long stems of these gloriously scented blooms, a few of which suffice to fill a whole room. Following hard upon the heels of this comes the wonderful Iris reticulata. This flowers—more or less—according to the season in February, although in a backward year I have known it to be early April before the first blooms expanded. The colour of the flowers, one upon a stem, is violet-purple heavily reticulated, with darker veins of a similar colour and a vivid orange stain in the middle of each fall. In order to encourage the earliest



WALLFLOWERS, RICH IN COLOUR AND FRAGRANCE.

Digitized by Google

flowering, a sunny and well protected position should be afforded, while a well drained soil is absolutely essential. Rich soil must be avoided, as it encourages rank growth and, when this occurs, flowers are sparse because the bulbs fail to ripen fully. As an edging to large or small borders—it is only a question of varying the width of the planting—Milla uniflora is excellent and has the advantage of, unlike so many bulbous flowers blooming successionally for some time. The English name, spring star flower, conveys a very fair impression of the blooms, which are white, shaded with blue and deliciously scented. Yet another bulbous subject, which is rarely met with in gardens, is a variety of the muscari—moschatum or musk-scented hyacinth. This is not at all a conspicuous flower, for the little spikes of bells are greyish purple that fades off to yellowish brown, but the perfume is powerful and well justifies the name of musk hyacinth.

MYRRHIS ODORATA, SWEET CICELY WITH GRACEFUL HABIT AND FINE FOLIAGE.

Still among the bulbs, the poetaz narcissi are splendidly fragrant flowers that have abundantly vindicated their claim to complete hardiness. With the older polyanthus bunch-flowered narcissi it is a gamble whether one will get one's flowers or whether frost will nip them; but with the poetaz varieties one is quite sure. Size, colour, clearness of eye and fragrance are all beyond praise, and small groups disposed here and there in the borders make a most effective addition to our range of fragrant spring beauties. Polyanthus in mixture, whether in patches in the borders, as edgings or entire fillings for beds, etc., are so well known that no more need be said, for their spring-like fragrance is also abundantly appreciated. Stronger and more distinct than this in its delicate perfume is the auricula, another of the vast primula family, and he who owns a rich supply of these may certainly congratulate himself on the possession of a double store of treasure, for nothing else quite equals the glorious velvety texture and wonderfully rich colourings that are to be found in this best of all spring flowers for the hardy garden. A coarse-growing and common old plant that is, however, by no means devoid of scent and that gives wonderful cascades of snowy white flowers is Arabis albida fl. pl., but it should never be forgotten that this is such a rampant grower that it is only suitable for certain places in the garden where its smothering capacity cannot act to the detriment of other and choicer plants. Like a giant snowdrop, Leucojum vernum (the spring snowflake) is worth extensive planting, and may well appear in bold clumps in the rock garden, the shrubbery and the mixed border, wherever a touch of spring is desired. The drooping white flowers, touched with green at the tips of the petals, are a delight for cutting, and it is when used within doors that the delightful fragrance may be best appreciated.

Among the later spring-flowering bulbous rooted plants one finds a most unusual tulip that deserves to be far better known, for it is not costly and goes on year after year with no further attention than the preliminary planting. It is quite dwarf in stature, not more than 3ins., but even at this produces several fragrant flowers on each stem. A very sunny place should be allotted to the bulbs, for the flowers only expand when this is shining. The colour on the outside of the petals is golden bronze, while the inside is deep buttercup yellow, forming a very striking patch when the blooms are widely expanded into stars in the warm sunlight. One mentions Myrrhis odorata among the fragrances of spring because that is when it begins to flower, although this is carried on into early summer, and even after that one has the value of the graceful habit and the deeply divided leaves.

Before we realise that spring is passing we glide imperceptibly into the world of early summer, when the Spanish iris, the rockets and the pinks begin to expand and fill the air with new and delicious odours; but perfumes increase so rapidly just then and the number of varieties is so great that we must leave their consideration for a further article.

H. W. CANNING-WRIGHT.

THE "CHARM" DAHLIAS

If you get simple beauty and nought else,
You get about the best thing God invents.
ROBERT BROWNING.

THE simple beauty of the "Charm" dahlia is its greatest attraction. There is a single or double row of ray florets, a yellow disc, a wide range of pretty and in some instances almost indescribable shades and a thin, rigid flower stalk which gives grace to every bloom and makes it an invaluable subject for decorative purposes. There is no perfume—we do not expect it in a dahlia. I like, too, the simple beauty of the name. The word "Charm" fits the flower exactly. It is as delightful in the garden as it is when tastefully arranged in the room. To call them "Charms" is much more acceptable than to use the rather formal term of miniature peony-flowered dahlias. When this type was first introduced—and no person has worked more assiduously in their evolution and perfection than my good friend, Mr. Ernest Doncaster—there were many critics who scoffed at the idea of the "Charms" becoming popular. "We can obtain equally good flowers," said these critics, "from any mixed packet of dahlia seed." This idea is an illusion. The increasing popularity of the "Charms" is a practical answer to such an assertion.

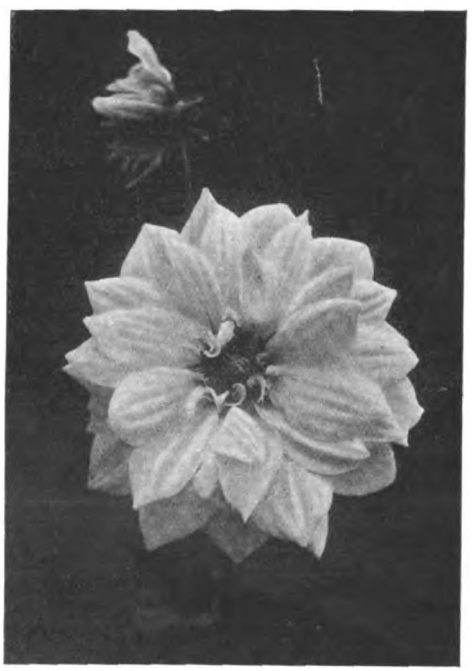
An open site that is well sheltered from the prevailing winds suits the "Charms" admirably. The ground may be forked over some weeks before planting time and a liberal supply of well decayed animal manure worked into the soil at the same time. A sprinkling of bone meal and superphosphate is also beneficial. If time or circumstances do not permit of such preparation being done, all that is necessary to ensure success is to mark out the position of each plant and dig out a hole about 2ft. deep and fork into the lower spit of this a spadeful of manure, with a handful of artificials scattered in as the soil is replaced. Planting out may be done any time between the third week in May to the beginning of June. Early plantings are advisable, as the plants benefit by the favourable growing conditions of late May or early June. Firm planting is necessary. Usually the young plants are received from the nurseries thoroughly hardened and ready for their permanent quarters, and in most cases they are sent

Digitized by Google

with the ball of soil intact. The plants do not show much visible change for the first few weeks after planting, but when once they become established they make rapid growth and necessary staking and tying should be done so that winds will not damage the sappy shoots. Ordinary bamboo canes are stout enough for supports as the plants seldom attain a height of more than 4ft. The average height is about 3ft. and the weight of the plant is not as heavy as the larger-flowered types.

All the " Charms " are free flowering, some of them being very floriferous. All faded flowers and seed vessels must be removed regularly in order to obtain a continued display of bloom. The plants will commence to flower in July, and if well grown will produce an abundance of bloom until the frosts cut them down. Some of the popular kinds, and in some cases the cheaper ones, are among the most beautiful, so that even a modest outlay will be many times repaid. Two of the prettiest of these—the forerunners of the race—are Norah Bell and Our Annie. Norah Bell is a lovely bright cerise on a yellow ground, a colour that is brilliant in sunshine and exquisite under lamp-light. The nearest colour in flowers that I can compare it with is the beautiful Cottage Tulip Cassandra. Our Annie is a soft shade of shrimp pink on a yellow ground. The yellow ground " Charms " are all delightful in artificial light, besides being attractive colours in the garden.

Little Edie, a different type of bloom from Our Annie, has much of the latter's beautiful colouring. It is a dwarf, bushy plant, and at its best is always a mass of bloom. Picture is another well known variety. The colour is very difficult to describe, chestnut and flame on a gold ground is the nearest approach, but there are many other pleasing shades intermingled in its colour composition. It is a variety that only needs to be seen to be admired. Gladys Unwin, another very free flowering type and a plant with a good constitution, is one of the best pinks. The distinct lemon zone in the centre lights up the flower and gives it an added charm. Elegance is a soft, silvery rose-pink, a very delicate colour, and the blooms are very freely produced. Rosie is a deep pink, but the colouring is soft and pleasing. This s also very floriferous. Trixie is an orange scarlet self, a colour that is somewhat like the early Tulip Prince of Austria. It makes a bold splash of colour and is one of the brightest for garden display. Crimson Glow is another rich self, an intense deep crimson. The flowers are freely produced and the stems are erect, strong and of great length. Dazzle is a brilliant scarlet that is consistently good. The flowers are of medium size and are carried erect on very rigid stems. This is a good variety for bedding or massing. Fusee is a softer coloured Norah Bell, one of the loveliest colours for room decoration in artificial light. It is very free-flowering and the stems are wiry. Other useful standard varieties include Bertha, bright rose suffused with crimson at the base, one of the freest of the " Charms "; Epoch, a brilliant scarlet flame with rosy tips; Jess, orange suffused with scarlet, a fine erect grower; Judith, rust red, an uncommon colour; Kenneth, a beautiful shade of pink; Marcella, a glowing rose with a golden base; The General, a distinct shade of madder crimson; and The Quest, crimson-scarlet with a yellow base.



A TYPICAL "CHARM" DAHLIA.

I have had the privilege of growing several of the novelties in advance and the new varieties that were offered last spring have had two season's tests in my garden. Most of these are great advances both in colour, type and habit. Three of the 1924 introductions stand out prominently. These are Charmer, Dennys and Amos. Charmer is one of the finest, if not the best " Charm " in cultivation. It fully deserves the award of merit which it received at the Wisley Trials last year. The predominating colour changes from orange-chestnut to orange-salmon overlaid on a rosy ground. It is impossible to give an accurate idea of the wonderful colour blend. The flowers are well formed, of great lasting qualities, and they are freely produced on erect, rigid stems. Dennys is a glowing orange-scarlet self. There is more scarlet in it than Trixie and it is quite a different colour. It is a nearer approach to vermilion. There is a beautiful gloss on the petals and a bunch of this variety is positively dazzling. It has a perfect habit and is very free flowering. Amos is rather larger than the ordinary type, but it is such a perfectly proportioned flower, and the brilliant crimson-scarlet colour is reminiscent of our best velvety-crimson roses. This is one of the most brilliant " Charms " we have. Three other 1924 introductions are almost as fine as the foregoing. These are Mac, Peach and Betty. Mac is an art shade of fawny salmon on a yellow ground. It is a bold, well formed flower and the blooms are held erect on good stems. It has a vigorous constitution and its perfect habit makes it a good subject for garden decoration, while there is no more pleasing colour for artificial light. Peach is a delicate rose on a lemon ground. The centre of the flower, where the lemon base is more pronounced, and the dainty wire edge of crimson on each petal give it a soft and beautiful effect. Betty is a silvery lavender-lilac. Last season it was particularly good in colour here, and although it is not a colour for lamp-light, it makes a good contrast in the garden, and it is quite distinct. Lillah, a deep pink with white tips on each petal, a perfectly formed flower, and Leonie, a light rosy pink with a yellow zone, are both attractive new shades.

I have tried all the best novelties of 1925, and there are some excellent additions among them. Emily is the best yellow " Charm " to date. It is a pure shade of primrose yellow with paler tips. It has a fine erect habit. Electron is a yellow ground overlaid with brilliant orange-crimson, the tips of the florets being suffused with violet. When the sun shines on this variety it seems to light up the flowers. It is so free that as many as fifty flowers can be counted on a plant at one time. Chameleon, as the name suggests, changes its colour from salmon-orange to rosy-orange and later paling to rosy buff tinged with orange. It is a fine flower of the " Charmer " type. Emma is the nearest approach to a white. Except that the base is slightly tinted with pale sulphur yellow it is virtually a self. Angelina is a brilliant shade of coppery orange toned with scarlet and orange crimson. It is a free-flowering variety of the " Picture " type. Kitty is a soft rosy pink with the centre of the petals slightly suffused with crimson. The base is chocolate-maroon. It has a free branching habit and is very useful for cutting, as the blooms will last for eight or nine days in subdued light. Lucina opens an apricot buff and changes to reddish salmon. It is a distinct and pleasing colour and is very pretty in artificial light. Mary is a brilliant maroon crimson, the darkest " Charm " yet raised. It is a fine colour and reliable in all other respects.

The blooms are at the right stage for cutting when the second row of disc florets are opening. For brilliant effects use orange scarlet, pure scarlet or crimson. Any of the pinks, more particularly those where the yellow or lemon zone is clearly defined, are suitable for table decoration. The cerise and salmon cerise shades are seen at their best when placed near the source of artificial light. Yellows may be seen in small proportion with the richer shades of pink. A mixed vase is quite pretty, but carefully arranged groups give the best effect. The flowers do not need foliage or grasses mixed among them. These rather spoil their beauty. The spikes should never be crowded. A dozen sprays will be quite sufficient for an ordinary vase. A rose bowl makes an admirable receptacle. There is no autumn flower more useful for decorative work than the " Charm " dahlia, by reason of their wealth and variety of colour.

NORMAN LAMBERT.

EUCRYPHIA CORDIFOLIA

IN many gardens, even in localities particularly suitable for the less hardy shrubs, considerable difficulty is experienced in establishing this beautiful, but somewhat tender tree, or shrub. Stunted, leaderless plants are common, and this when the site has been well chosen and prepared. What is the reason? After examining many such plants, I am forced to the conclusion that very few ever get a fair start. Autumn planting, with wintry conditions following before the plant is established or protected is responsible for many failures. Planting unprepared plants, such as have been grown closely together in shaded houses, is another cause. Again, a plant may be pot bound and the roots inactive when it is planted, with the result that time is lost and growth commences too late in summer and is not matured before frosts occur. There is also the question of varying hardiness in individual plants. This would not affect those rooted from cuttings in the same degree, but seedlings vary considerably, some grow away with a distinct lead and very vigorous foliage, and are at three years old, 18ins. in height. The majority form neat, well branched little trees of 10ins. to 12 ins. Others, the dwarfs, grow slowly and only attain 6ins. in height in the time stated. Curiously enough the free-growing plants appear to be the hardiest. Loss of the leading shoot by frost may cause some plants to branch freely, but in most the difference in habit is due to seed variation. Such plants, where they succeed, will make beautiful shrubs no doubt, but never stately specimens. When the latter are desired, good plants, grown with as little check as possible, should be chosen.

In a mild season like the present the roots should be active and if it is intended to plant out into a permanent position in April, no time should be lost in giving a liberal increase in pot room. A mixture of two parts loam, half a part leaf-mould, half a part peat and a good sprinkling of sand, makes a suitable compost. Pot moderately firm and place in a cool house or pit, inure to outside conditions previous to planting out in the middle of April.

A somewhat sheltered but sunny place should be chosen. Soils which suit rhododendrons, well drained light loams, and those of a peaty nature appear most suitable. Double dig the ground, a space 6ft. each way is none too much, forking in leaf-mould and sandy peat if necessary. Examine the plant; vigorous roots should now be pushing through the new soil, be careful not to injure them or break the ball, plant and stake at once, making the soil firm below, leaving a good tilth on the surface.

In young plants, growth is rarely finished before November and the points are often browned and sometimes killed by frosts. The best method of protection is to mulch the ground over the roots with leaf-mould or even cinder ashes, and, using five or six bean sticks, make a "wigwam" over the plant, tying the tops of the sticks together some distance above it. Then cover all but one quarter, that on the sunny side, with a Russian mat. Arrange a flap, to be tied across the opening in severe weather. Protecting tender trees and shrubs is often of doubtful utility, but in this case it means all the difference between success and failure. When the stem has attained some solidity and is well protected by ample foliage, it is not so necessary.

J. COMBER.

A BEAUTIFUL FLOWERING SPRAY OF EUCRYPHIA CORDIFOLIA.

THE CULTIVATION OF THE VIOLET

THE humble violet with its sweet scent and lovely colour will always be welcome. This year violets have been very plentiful, and the sight of so many of these much-loved flowers must make some people wish that they were growing them in their own gardens. Those who contemplate doing so should begin now, and by next autumn they will reap the reward of their labours during the summer. Undersized and poor flowers can be produced practically anywhere and by the most incompetent gardener, but to get the very best a certain amount of care and understanding of the needs of the violet are essential. It takes skill to produce flowers during the dull dark days of winter, and also to keep up a succession of bloom from September to April.

First of all, the violet must have sunshine and air. The smoke-laden atmosphere of a town is fatal to them. Not only are the flowers meagre and scarce, but the leaves are few in number. Fog also is most injurious. Very often violets are planted in a shady position, whereas an open sunny situation where the crowns of the plants can be well ripened, is one which the violet loves. Slight shading during the very hottest part of the summer is helpful, but directly the days are cooler the violets should be fully exposed once again. Unfortunately, red spider is likely to be troublesome in a sunny position, but this difficulty can be overcome and should not hinder anyone from planting in an open situation.

Violets succeed better in some soils than in others, but on the whole they are not particular. A good medium loam is ideal, but other soils can be made suitable by the addition of manure or leaf-soil and by well working the land. A really heavy soil must be drained, as good fibrous roots are not made in a water-logged soil, and without them the plants are not healthy. Any material which will improve the physical condition, such as a good dressing of lime, should be added to a clay soil. Leaf-mould, cow manure or farmyard manure will improve sandy soils and help to keep the roots of plants in a light soil cool and moist during the summer. Violets do not in nature grow in a soil heavily charged with manure, but in a soil rich in humus. Large quantities of manure cause the flowers to be few and far between. Old mushroom manure

Digitized by Google

or the remains of a hot-bed are excellent additions to the violet site.

To produce first-class violets, good stock is essential. Any grower, who has not up to the present been successful with his violets, should begin again with fresh stock. Those who are starting for the first time should purchase young rooted crown runners from a reliable grower who specialises in violets. A good beginning is half the battle.

Single, double and Parma violets are, with a few exceptions, treated in the same way. Annual propagation is the best method, and if possible fresh quarters should be given each year. Cuttings of single violets can be taken in spring and in the autumn, or the old plants may be pulled to pieces directly after flowering and replanted in prepared beds. A limited number of plants should be set aside for stock plants each year and allowed to develop runners. Vigorous outside cuttings with good roots from the best plants should be selected. When all the cuttings are gathered together they should be prepared before planting by removing any inferior leaves and cutting off the runners. After this they should be planted with a trowel in well dug beds manured the previous autumn, placing them 14–16ins. apart each way for the singles and 12ins. for the doubles. It is very important that the cuttings should be planted *firmly*, but the crown must not be buried. When the young plants are given a pull they should not come out of the soil. To ensure firm planting, the ground should not be spongy to start with. Rolling with a wooden roller or treading consolidates the soil.

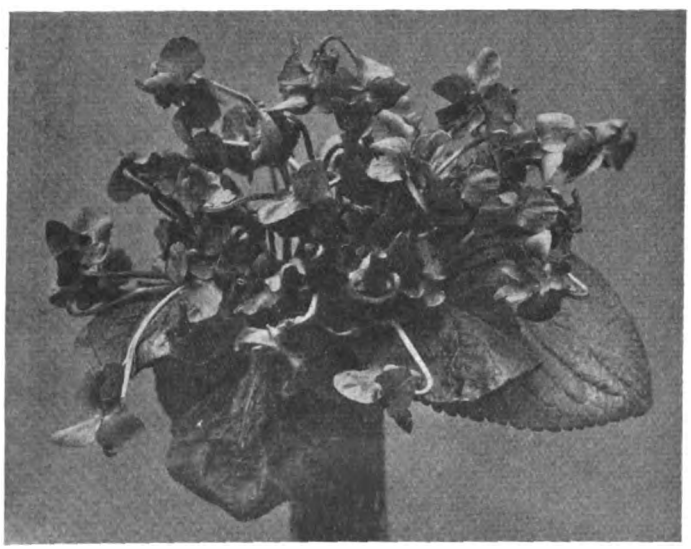
Parma violets are usually propagated by division of the old plants in spring as soon as flowering is over, and strong outside crowns only should be used. About 10ins. apart in the beds is sufficient distance for planting the Parma violet. Runners can be taken off in March and inserted in boxes and placed in a cold frame. These should be kept growing well, and in six or eight weeks' time they will have formed good plants for planting outside. In all cases it is advisable to plant the violets as soon as possible, as they are then able to withstand drought more easily during the summer. Until they are established no attention need be given; but, after that, weeding, hoeing and watering must be done regularly. All through the summer the runners should be nipped off so that strong individual flowering clumps will have formed by the autumn. Autumn-struck cuttings sometimes root more easily, as there are no drying winds then. A few plants can be allowed to develop runners; these will provide cuttings for striking in the autumn in frames. Liberal supplies of water should be given in dry weather, and the plants must be syringed frequently to keep down red spider, and if this pest attacks the plants, syringe with paraffin emulsion. Every fortnight a weak dose of liquid manure should be given. In this way fine clumps will be formed.

There are two seasons of flowering, from September until the nights are frosty, and then again during February and March. To obtain bloom from November to January some means of protection is necessary. Portable frames can be placed over the rows, but moving the plants into frames where they can get as much warmth as possible is the better method. This protection during the winter does away with the chances of damage by rain. At the beginning of September the Parma violets are lifted and at the end of the month or early in October the singles. If there are any flower-buds showing at this time, they should be picked off. The frames should be well drained and contain a fairly rich compost, and the ground should be made firm before planting. A frame in which cucumbers have been grown is quite suitable for violets during the winter. The day before lifting soak the violets well. Take up with a large ball of soil, remove all dead leaves, and plant firmly in the frames and near the glass. The plants should be 12ins. apart and the crown must not be below the soil. Water immediately and place the lights on for the first fourteen days. During these first days some ventilation and shading should be given to prevent the leaves from flagging. When the violets have become established, remove the lights and do not replace until the nights turn cold, and even then a little air should be given at night and plenty during the day. In frosty weather cover the lights with mats at night as a means of protection.

Throughout the winter all decayed leaves should be picked off and the soil stirred with a hand fork every fortnight. Violets will need very little water during the dead months, and great care must be taken that they do not suffer from damp. If damp does get in, sprinkle a mixture of powdered lime and charcoal round the plants and in the crown. Ventilate whenever possible, especially as spring advances.

There are a number of good varieties of violets, and to keep up a succession of bloom several kinds should be grown. Undoubtedly the best all-round variety for outside or for frame culture is Princess of Wales. Admiral Avellan is a good deep amethyst variety. Mrs. Lloyd George has dark violet flowers with a coloured rosette in the middle of each. Baroness de Rothschild has a particularly large purplish violet flower. Cœur d'Alsace is grown because of its pinkish red flowers, which are so different from the usual violet colour. The flowers are not large, but they are sweetly scented and continuous blooming. White Czar is the best white violet, it has small well shaped flowers. All the above varieties are singles.

The well known varieties of Parma violets are still the best. Marie Louise has a beautiful deep blue flower with a streak of red in the centre. Duchesse de Parma, although a rather pale blue, is worth growing owing to its sweet fragrance. Mrs. J. J. Astor is a large-flowered dark amethyst variety; and Mrs. Arthur is dark blue with a white centre. Comte de Brazza is an excellent white Parma violet and is very fragrant.



A GOOD VARIETY FOR OUTSIDE CULTURE, PRINCESS OF WALES.

MARIE LOUISE, WITH BEAUTIFUL DEEP BLUE FLOWERS.

HOW TO MAKE A PRIVATE GARDEN PAY

IT IS THE AIM OF THE MAJORITY OF GARDENERS AND OWNERS OF GARDENS TO MAKE THE GARDEN AS PROFITABLE AS POSSIBLE WHILE RETAINING ITS BEAUTY AND GRACE. IN THIS, AND THE FOLLOWING ARTICLES, THE WRITER SUGGESTS CERTAIN CROPS WHICH MAY BE TRIED WITH A VIEW TO MAKING THE PRIVATE GARDEN A PAYING PROPOSITION.

IN these days of depreciated investments and tight money generally, many owners of large and medium sized estates are directing their attention to the commercial possibilities of utilising surplus garden produce.

In many country places I know of, gardeners are chosen for their commercial as well as technical training, and through them very useful alterations have been made by diverting establishment charges into profitable channels, and, in addition to supplying the owner with all his requirements, the gardens have been made to pay their own way.

Let me say at once that no acts of vandalism are necessary; there is not the slightest need to destroy the beauty of any garden by making it pay. Some re-arrangement will be needed in the nature of the crops, cultural treatment will differ too, somewhat, since medium-sized fruit, flowers or vegetables will be the aim rather than a few exhibition specimens.

It is possible to some extent to mix the purely ornamental with the prosaic commercial sections, more especially with flowers; but forced salads and vegetables, as well as outdoor fruit crops, must be segregated from the domestic sections, for they will pay well for the extra attention afforded. Correct successions must be maintained, for the essence of good marketing is to secure and maintain a market reputation, and this can only be successfully accomplished by maintaining a continuity of supply of high-grade goods.

The adoption of my suggestions may mean the elimination of unprofitable varieties, especially in fruit and flowers, substituting other kinds just as beautiful but possessed of a definite market value. The intensive and continuous use of hot-beds, heated frames and greenhouses, together with the right use of all by-products, will be involved.

I propose to deal with the main sections individually and from a commercial standpoint, but the amateur may safely follow in practice the cultural instructions given. He will differ only in that he may wish to add types and varieties which would ordinarily have no place in a commercially conducted garden.

Before I go into cultural details, I would like to warn my readers against trying to compete with the commercial grower of the commoner necessities, such as potatoes, cabbages and the like. The aim should be to take very full advantage of sheltered positions, soil, and the general intensive conditions of the private garden.

GROW CHOICE THINGS OUT OF SEASON.

Tackle that which, by the very nature of things, the grower in a large way cannot. Forced strawberries, asparagus, seakale, mushrooms, beans, mint, lettuce and new potatoes are all in very great demand on the market, and are extremely profitable. I have, from quite a tiny cucumber house, sent

DAFFODILS READY FOR PACKING FOR MARKET.
Note how this is carried out with all the heads at one end.

large quantities of forced mint to Covent Garden in February, March and April, and have received from 12s. to 15s. per dozen bunches—and remember that mint can be cut four times, given correct treatment. Ten shillings per pound for forced beans is not at all an unusual figure, and I have made more during a shortage of French sendings. New potatoes at from 2s. 6d. to 3s. per pound show a good profit, with not a very large or exorbitant outlay. Careful attention to detail and an intelligent appreciation of the market fluctuations are all that is necessary, all other things being equal. I shall endeavour to make the articles as topical as possible, so that those intending to try may do so at once. The first subject to be dealt with is bulbs and flowers. If, as we go along, difficulties crop up or something is not quite clear, I should like to know, so that all readers may benefit by the reply. More useful information is acquired through intelligent discussion and constructive criticism than in almost any other way. Further, each district, and almost each garden, has its own special problems of which I cannot be cognisant when writing in general terms. I shall welcome these particular problems, for principles may always be applied and adjusted to local conditions in gardening as much as anything; the rule of thumb means stagnation and horticultural mediocrity.

PLANTING OUT MINT CUTTINGS IN PREPARED BEDS.

BULBS AND FLOWERS.

Of all the forms of commercial horticulture, this is, I think, the most profitable and interesting. There is always a steady demand for British bloom right up to the end of March and April, and the keen gardener will see that a succession of flowers is maintained right through the season, commencing from Christmas. For the purposes of this article, I am assuming that no bulbs are being bought in specifically for forcing, and will deal

Digitized by Google

with the subject right from the commencement when the bulbs are being planted, up to the time the flowers are ready for market.

Preparations have to be made a year ahead, and the bulbs for forcing in the winter of 1925 are now planted and growing. To commence operations it is necessary either to buy or lift a stock of "mother" bulbs during the month of July or August. Most gardeners know what a "mother" bulb is. Commercially it is one which has been planted down for three years and has developed from a single "offset" to a group of tightly packed small bulbs. It is the large flat-sided offsets which are planted down for forcing. After the main beds of bulbs have been lifted, they are left on the surface of the ground to dry and ripen. When first lifted, the offsets are very tightly fixed to the parent bulb, and it would cause great injury to divide them at this time. A few days' drying causes them partially to break away, and a little hand assistance then is all that is necessary. They must never be forcibly removed, or irreparable injury will be caused to the root plate. When all the bulbs have been graded, there will be found four sizes and types, no matter what variety of bulb is being treated. First come the parent bulbs from which the offsets have been removed, then the large offsets, then more a little smaller, and finally tiny little bulbils. The last may be thrown away, or planted in some woodland place, for they will take many years to mature into flowering bulbs. All the others must be planted into raised beds in their separate grades. The beds are very like asparagus beds, and about 6ft. wide. This is to allow flower picking from each side of the bed without stepping on it. The parent bulbs will flower in the season following planting, and at the same time grow into round bulbs fit for forcing or planting down for three years for stock purposes. The large offset may flower, but, at the same time, will become round and suitable for forcing in the following year. The smaller offsets must be planted a little deeper—about 5ins.—and remain for two years before being fit to lift again. So it will be seen that the life history of a bulb involves three years; but as soon as established, all is plain sailing. From the commercial point of view, the beauty of bulb and flower growing is that all the time revenue is coming in in the form of flowers, one's capital in the form of bulbs is steadily appreciating. During the months of August and September the round bulbs will be boxed or potted ready for forcing, and then should be plunged either in beds of fine soil or ashes until the time comes to bring them into heated greenhouses. This time should be determined only by the condition of the bulbs and not by the time of the year. I have seen more failures in forcing through bringing in the boxes prematurely than through any other cause. The flower should just be emerging through the neck of the bulb before heat is applied, and then it will stand any reasonable amount. If brought under glass too soon, then the foliage takes the lead and maintains it throughout, while the flower becomes stunted and deformed and quite useless for market. It will be found that all the polyanthus narcissi, such as, for example, Soleil d'Or, will stand much more heat than will the Ajax or trumpet kinds. Here we may leave them until the flower spikes are well up in the sheaths and the head of the bloom is just "crooking" over and the petals commencing to open. It is at this stage that the difference as between commercial and private work is obvious. The flowers must be picked now, if it is intended to market them, for they will have to undergo a period of development under cool conditions so that they may "harden" and have their natural colour intensified. While still green, therefore, and long before they are fully opened, bloom should be picked, in the early morning, and taken at once to a cool, *sunny* and light place and be placed in water tied up in bunches of two or three dozens, *loosely* tied up in bunches of three to four dozens. All having been picked, they should be taken out and put in either in a cool sunny glass house or shed. They must, of course, be put in water.

After a twelve hours' drink a remarkable change will have taken place. The blooms will have partially opened, and will be firm and a little on the green side. It is at this stage that the grower should market the bloom, and in no case when it is fully developed. It should be remembered that it has to travel to the market, be exposed for sale, it may then have to go on another long journey to some provincial town, and the retailer then has to keep it for a day or two in his shop. *The flowers should not be fully developed even when they reach the retailer*, for he has to consider the consumer, naturally, and will invariably pay a higher price for that which will last longest.

Exactly the same procedure is followed with the outdoor bloom, with the exception that the buds should be a little more developed before being picked.

MARKETING THE FLOWERS.

Flowers grown in a private garden should be a much better grade than the ordinary commercially grown bloom, and this being so, Covent Garden Market will form the best outlet for them. Higher prices are paid in this market for high-grade material than any other market in the world. After the flowers have been tied up in bunches of one dozen blooms, they should be packed in non-returnable wooden boxes which any salesman will supply. According to the variety of flower, the number of bunches in a box will vary. The packer should not be afraid of packing the bloom firmly; far more harm is done by loose packing than otherwise. With most of the trumpet varieties of daffodils it will be found that two layers of a dozen bunches in a layer will be quite satisfactory. The heads of the bunches should all be packed at one end of the box, in order to display the length of stem, and a light wood "cleet" should be firmly wedged over the stems to keep them rigid in transit.

Before packing, the stems should be quite dry, and this will necessitate taking the bunches out of water at least two hours before packing, and standing them upright on a draining board. Pack early in the morning of the day of despatch and advise the salesman the night before of the quantity and variety of your consignment. Better prices are always obtainable when the salesman knows what to expect, and after he gets to know your "mark" (as it is called on the market) your sendings may be sold at the very highest market prices before they have arrived. Such is the value of a good market reputation. Here are some of the best commercial varieties of daffodils and narcissi to grow. There are many hundreds of other varieties, and some are much more beautiful than those given, but, as they are not well known on the market, it is too much of a gamble to recommend them.

COMMERCIAL VARIETIES OF BULBS TO GROW.

The amateur in flower growing is very apt to want to indulge in too many varieties, with the result that he has a great number of small consignments which are anathema to the salesman. It is far better to have larger quantities of fewer kinds. Remember that each variety should be sent in dozens of bunches, or multiples of a dozen. Odd bunches are a nuisance and cause endless trouble in the sales returns. Here, then, is a short list with which the beginner might make a good start by obtaining, say, 2cwt. of each variety. They would, of course, be purchased at wholesale rates and "as lifted," which means that all the offsets, "mother" bulbs and so on will be included, and will be graded out before planting by the purchaser.

SOLEIL D'OR.—Good for warm climates, such as Guernsey, Scilly or Cornwall. Very good forcer.

GOLDEN SPUR.—The best commercial daffodil. First-class forcer.

PRINCEPS.—A good bicolor daffodil and a good forcer.

EMPEROR.—A well known market variety and will force.

EMPRESS.—Ditto (bicolor).

BICOLOR VICTORIA.—Ditto (bicolor).

KING ALFRED.—First-class market variety. Forces well. Large daffodil.

BARRII CONSPICUUS.—Heavy cropper. Will not force.

POETICUS ORNATUS.—Best known commercial narcissus. Fine forcer.

HORACE.—Beautiful flower—makes good money always. Bad forcer.

SIR WATKIN.—Good commercial daffodil. Always in demand. Forcer.

FRANK MILES.—A sturdy Incomparabilis type, will not force well.

LUCIFER.—Ditto.

C. J. BACKHOUSE.—Ditto.

RECURVUS.—Useful for Easter work, and very hardy. Good forcer.

DOUBLE WHITE.—A late Easter flower, and therefore very valuable where it will do.

In my next article I shall deal with glass house work from the viewpoint of growing commercially profitable crops.

SIDNEY P. WELLS.

FLOWERS BY THE SEA

THERE are numerous owners of villas with small gardens near the sea which are only used for week-ends and during a few months in the summer, and where, perhaps, the services of a jobbing gardener are only employed occasionally to tidy up. During most of the year the plants in the beds and borders have practically to take care of themselves.

My idea in writing these notes is to recommend a few varieties of hardy plants which, with very little attention, will make a good show during the summer and early autumn.

It is as well to remember that soil near the sea is generally of a sandy and "hungry" nature and dries out very quickly; consequently, the ground must be well prepared if the plants are to be successfully grown. Before planting, trench the soil at least 2ft. deep, and work in plenty of good rotten manure.

The chief drawbacks to being near the sea are the strong winds which are experienced at all times of the year, and more especially during the early spring months. Therefore, unless the garden is situated in a sheltered position, it is useless to plant tall-growing varieties. Speaking from my own experience, those I recommend do really well and, if properly planted in the first instance, will afterwards take care of themselves and not require to be shifted for at least two or three years.

When planting a border of hardy flowers it is as well to allow plenty of space between the plants. Perennials such as Canterbury bells and sweet williams, which only flower one year, may be dotted in between, and bulbs such as gladioli and Hyacinthus candicans may also be planted in the spring. Some of the favourite annuals, such as mignonette, cornflower and larkspurs, should be sown. These look gay during the summer and are very little trouble.

Three flowering shrubs which do well are Forsythia Fortunei, with drooping yellow flowers freely produced during April. Olearia macrodonta, a distinct shrub with cut silvery leaves and sweetly scented white flowers, and Spiræa Anthony Waterer, a compact shrub with large heads of bright crimson flowers.

The following hardy plants are a few I recommend, although, of course, there are many others:

Achillea Perry's White.

Aquilegia.—Long-spurred hybrids.

Michaelmas Daisies (Asters).—Ideal (pale lavender), Delight (white), Lil Fardell (silvery rose).

Campanula persicifolia. C. p. alba.

Gaillardia.—Lady Rolleston, The King

Geum.—Mrs. Bradshaw, Mr. John Bradshaw.

Gypsophila paniculata flore plena.

Helenium.—Riverton Gem.

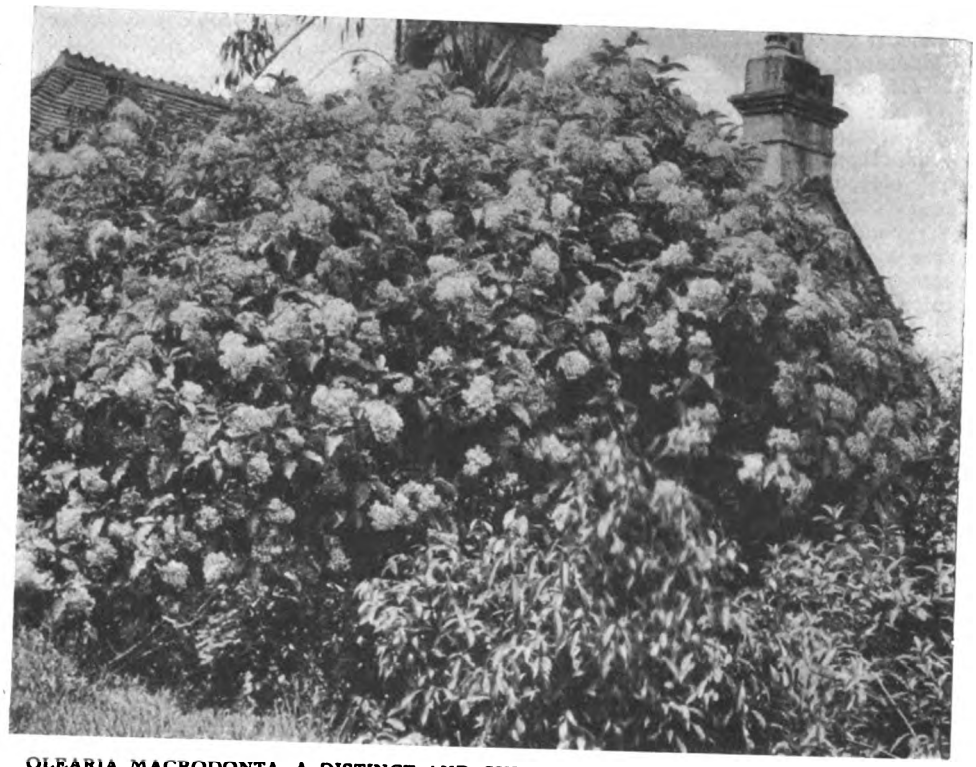
Iberis gibraltarica (very suitable for edging).

Iris.—Amas, Aurea, Caprice, Cordelia, Gagus, Kitty Reuthe.

Nepeta Mussini (catmint).

Peony.—Mme. Eugêne Verdier, Albert Crousse.

Phlox.—Elizabeth Campbell (a lovely salmon-pink), Regulus.



OLEARIA MACRODONTA, A DISTINCT AND SUITABLE SHRUB FOR SEASIDE GARDENS.

Chrysanthemum maximum.—Mayfield Giant, Mrs. C. Lothian Bell.

Erigeron.—B. Ladhams.

Scabiosa caucasica.

The tallest of the above varieties only grows to a height of 3½ft. A. G.

VEGETABLES THAT ARE FLOWERS

WHEN your friends have finished showing you over the flower garden they are apt to say, "I don't expect you'd care to see the kitchen garden," but I always say, "You've seen the flowers, but now you *must* see my vegetables."

The difference between vegetables and flowers is not intrinsic in their nature, but one of the curious arbitrary classifications that man forces upon mere things. Flowers are plants which we cultivate for their beauty alone, while vegetables are plants which produce something edible: for example, the root of the parsnip, the bottom of the stem of onions, the top of the stem of asparagus, the buds of Brussels sprouts, the leaf stalk of celery, the leaves of spinach, the flowers of the globe artichoke, the fruit of the tomato, the seeds of caraway. By adding all these parts a composite, but complete, plant could be produced. Into this wooden scheme there is no consideration of any other factor than utility. That vegetables should be regarded as flowers because of their beauty appears to some minds an upsetting of the laws of seemliness.

It is a curious lack of balance in many people that they put beauty in one place and utility in another; this is an entirely modern conception, but there are a few exceptions; nobody seems to deny that a calf is delightful because it produces veal, or a baby chick any the less fluffy and lovable because it may grow into a boiling fowl or lay an egg. Those who think that beauty and utility are enemies should all be sent to the Tower, not to be beheaded, or even imprisoned, but to see the fine designs that are on cannon, coat of mail, halberd, strong boxes and many other objects which were clearly made for use.

A field of cabbages may be ugly, a field of cabbage stalks is undoubtedly an eyesore, but individually each cabbage is a huge green Victorian posy, and I am sorry that I am not big enough to put one in my buttonhole. In remote country gardens there are still flowers called "cabbage roses." With a little wise planning the gardener never need go into the garden and find it without its "cabbage posy." Cabbage is most attractive when the dew is still on it, for it is a plant that flags sadly in a dry warm atmosphere; so to see this flower at its best you must, in summertime, be up early.

What variety there is between January and December! The curly green kale of the early year has the grace and variegated outline of a fern, and during the grey winter days its vivid green is as gay as any red rose in June. Spring cabbage

Digitized by Google

is attractive because of the smoothness of its leaves, the inner ones having a texture like fine green satin. Purple sprouting broccoli is a kind of solid gypsophila, suitable for cold weather; it has lovely rich colours and its crisp and succulent stems are covered with a delicate lavender down. The bloom is as fine as that on a bunch of grapes and has the advantage that its beauty is within the reach of anyone who has a piece of garden.

One kind of cabbage posy succeeds another, and after some months we find the cream-coloured cauliflower, which some far-away, wise human being did dare to call a flower; its creamy white is set in a frame of green, rather like a mass of whipped cream in a green bowl.

The Old Year ends and the New Year begins with Brussels sprouts, little heads of fat men and women who have been caught by some witch and fastened to a stalk for their sins of over-indulgence, for how could they be so fat unless they had over-indulged? To make their punishment complete they are set out in a frozen garden, are bent over by snow and made to glisten by hoar frost. But in spite of their presumed discomforts, the little, fat, green men and women continue to grin and be jolly.

Nor must cabbages be forgotten in autumn, when frost and sun paint the outer leaves with red, orange and purple. Then mists keep a fine dew all day long on the reddened leaves and even the laziest gardener can see the posy cabbage at its best.

Next you must see the rows of waving plume-like carrots, fine and feathery from the first moment in which they so miraculously push their way through the hard brown soil until the first autumn frosts turn them into yellow-red. All the summer they have been like plants growing under the sea. I thought I looked down through blue-green water and saw the fine leaflets tossed here and there by the movements of the waves, but when autumn has begoldened the leaves they cease to be sea flowers that the mermaids pick and fix in their tresses, and become solid plants that live in solid earth. When the sun-coloured carrots are pulled out of the brown earth to serve as human fodder, it seems a pity that the fine green leaves, the lovely fine bunch of feathers that each carrot wears on top of his head, should have to be cut off and thrown away. Carrots are all men, but they bring a touch of femininity, or perhaps it is savagery, into their lives by their gay and delicate headdress.

Come down the walk that has a border of parsley, fine big plants of parsley which from their childhood have had plenty of space to grow in. Here is a notice in gardener's language that the missus is not bullied on this estate. Well grown parsley has a greenness that suggests intense gaiety; it outdoes the grass and promises an infinite succession of springs. If only it would never go to seed. The plant spreads out like a great green rosette, pale at the centre, deep green at the edge, each leaf placed exactly in the right place by a master designer. The mossiness of the newer parsleys is so soft and so rich that it does not seem quite at home out of doors. The plant seems to make an insistent demand that a leaf from the perfect rosette should be plucked to deck a piece of cream cheese, an anchovy sandwich or slices of smoked salmon. When properly dried on a sunny windy day it preserves its greenness and perkiness to the end.

Over there are the lettuces. To-day I cannot look at the cos: they are not flowers, but prim, hard-hearted spinsters who look as if they were trying to save their souls and be respectable. They can't even be of any use unless they are policed into their duty by being tied up! But the wonderful cabbage lettuce was invented by some wise labourer to make his garden lovely. Each leaf is a solidified wave of the sea, the outer green, the inner almost white; they stretch up into the air and curl about one another. Each lettuce is a lovely flower filled with secrets. The curling leaves embrace each other tightly in the cool, fragrant chambers where they dwell. But they will be spoilt if you let these lovely flowers grow into seeding vegetables.

How different is the asparagus bed. In its youth it is just a patch of delectable vegetables, rather desolate and unattractive looking, but when it has ceased to be useful it becomes a garden for the little woodland men and women who leave the gaily-coloured but rather solid flower beds to dance here under the fine leaves. The tiniest wind bends these plants; if we had better hearing perhaps we should discover that a thin sweet music sounded up and down this green bed.

It seems a little incongruous that such a delicate growth with its tiny flowers should produce a conspicuous, flaunting red berry. Perhaps the berries are compliments to the full-coloured summer sun, little lanterns that the woodland people hang up as offerings to the god of summer.

Beyond the asparagus we reach the sea kale bed, where palmate leaves grow cheerfully out of a bed of cinders. This is an exotic-looking plant and gives the garden a new colour, a misty greenish grey. The little curls and contortions of the edge are a combination of the laughs and grimaces which the leaf makes at each passer-by. It laughs because it does so well in spite of its cinder bed and its home away here in the damp and cold, and it also makes a grimace at you for having brought it to the north and made it a prisoner. It is bold because it is related to the pirates and buccaneers who sailed for so many centuries along the coasts of the Mediterranean. How plant and pirate are related cannot be known for certain, but probably a lazy pirate was turned into a sea kale, just as Adonis was changed into a flower and Arachne into a spider.

Another sea plant that has made a home with us is the rich red beetroot. Call them by some other name and we'd pick the leaves to put in vases in the house and plant them in the gaily coloured formal beds of big gardens and parks. The lovely leaves have a way of changing with the weather and the amount of moisture in the air, and become green, purple, red, grey, but they are always rich and beautiful. The modelling of the leaves is fine and the texture smooth and satiny.

It is a pity that potatoes do not blossom more frequently, as the purple or white flowers are very *chic* and attractive. Potato leaves are only nice after they have been sprayed with the blue-green disease killer, so it is the lady's "make-up" and not the lady herself who is admired. The potato itself is such a rough-looking customer that the dainty flower it bears seems hardly to belong to it. It is like an Apache passing off a lovely stolen child as its own. The prettiest part of the potato flower is the little beak of golden stamens which protrude out of the circle of white or purple petals.

For the last I'll save the best and most beautiful plant, the green or globe artichoke, which is grown so little but which might be cultivated in almost every garden in the southern and central counties. Its leaves are familiar to all in the acanthus decoration which we copied from the Greeks and which we know so well on the capitals of churches, theatres and town halls. It is a leaf that does not require modification, for it is perfect both in nature and in art. The down which is so abundant on the young leaves and the stalks gives it a soft appearance, but the beauty here is not texture or colour, but line.

Soon after the woolly frond has made its way into the air, its tip begins to bend earthwards; at first the curve is slight, but with increase of size the curve grows stronger and finally the tip may touch the ground, but in the whole progress from upright frond to procumbent leaf the curve is always fine, noble and alluring. The edge of the leaf is cut irregularly, but the cuts are not fussy like those of the sea kale or gauche like those of the dandelion. The cuts are clear, decisive, strong. At first the two sides of the leaf are close together, but as they grow they separate a little, then gradually open wide, each side making a fine curve outwards from the mid-rib. There is a great satisfaction in this leaf—a noble curve from base to tip and two graceful curves from midrib to edge, and the leaf is large enough to give a feeling of opulence in beauty. Nature in this plant does not give a tiny peep at loveliness as in a solitary pasque flower on the Downs, the sparse milkwort on an upland pasture, a tiny heartsease springing out of a hard baked field; but here are riches spread abundantly.

Inch by inch the stalk grows until it has reached five, six, seven feet, and as it ascends it sends off branches which bear the buds, cup-shaped like a thistle but without such unfriendly prickles. The green scale leaves, often tipped with purple, hold at their base that tiny morsel of food so delicious to the lover of artichokes and in the heart of the cup is hidden away the delectable *fond d'artichant*. If the garden is lucky enough to have a little rising ground, that is where the artichoke must grow for the sake of seeing its billowing leaves and curved cups undulating against the sky.

It has taken a year to see the vegetables; a year sounds so long, but it is only a very little piece out of Time. Rest just a moment and then we can start again.

O. A. MERRITT HAWKES.

POTATO GROWING AND INCOME TAX

BY A LAWYER.

GROWERS AND MERCHANTS.

A SOMEWHAT unusual question, of much importance in relation to the assessment of income tax of potato growers and merchants has lately been the subject of the close consideration of the High Court. The facts were quite simple. A firm of wholesale potato growers and merchants hired land under certain special conditions for the purpose of growing potatoes. They were in possession of the land in some cases for more than a year, and in other cases for less than a year, and the actual land used by them was changed each season. Their landlords, who were local farmers, did the ploughing and carting and provided the horse labour required, and the landlords were paid an agreed rate for rent and another sum, at so much per acre, for the provision of the necessary horse labour, etc., the amount paid being inclusive of all rates and taxes. The landlords were, however, assessed to income tax, Schedule "B" for the land, and not the potato merchants. The latter sold the potatoes grown by them under this arrangement and were assessed to Schedule "D," in London, where they carried on their business as potato salesmen, in respect of the profits which they got from this business in potatoes. The Inspector of Taxes contended that this was a profit which arose from the growing and sale of the potatoes, and not a profit arising from the occupation of the land.

OCCUPATION OF THE LAND.

The real point for the Court, therefore, was whether, under their agreement, these potato growers and merchants were, in fact, in occupation of the land in question. Under their agreement they were to have possession of the land until the potatoes were fully ripe and in fit condition to be stored in pits, and, in addition, they were entitled to certain rights of possession for the purpose of pitting their seed and storing their crops in pits until such time as the crop was sold and removed in the ordinary course of trade. The potato growers provided so much artificial potato manure to the acre, and the manual labour, except as previously mentioned. It was found, upon the facts, that the whole year and the whole value of the soil to grow anything was devoted to potatoes.

"USE" OF THE LAND.

What, therefore, was the use of the land for the particular year? The landlords, who, as stated, were farmers, let the potato growers the land as their tenants, and gave them possession of the land for their purposes. That being so the Court came to the conclusion that the growing of these potatoes was the only profit there was in the land. The Court also accepted the view that if the ordinary farmer grew potatoes, and took them, say, to London and sold them there, he would not be treated as commencing a new business from the time he took his crops from his farm on the way to market, although different considerations might apply to a farmer carrying on a butcher's shop, or anything of that sort. The fact, therefore, that these potato growers were also wholesale potato merchants and salesmen did not make them liable to be assessed to income tax under Schedule "D" in respect of the profits made by growing potatoes on the basis that this was subordinate to their business of potato merchants and salesmen. They were rightly assessable under Schedule "B" in respect of the occupation of land, and not their landlords, the farmers, although the latter were, in fact, the rated occupiers.

A NEW POINT.

It would not appear that any previous cases were of much assistance in settling the question involved, the decision in which is of great importance to those interested, for it would seem that a large profit had been obtained, making a great deal of difference if the assessment had been maintained under Schedule "D" instead of Schedule "B." The whole subject opens up a wide question for people who rent land for similar purposes and can justify their right to being assessed under "B," as occupiers of the land, under a working arrangement of this kind with the farmers from whom they rent, rather than being driven to be assessed under "D" on the profits of their businesses. It is true that in a bad year, with a loss in trading, they might be better off if assessed under "D"; but with a very considerable profit, as in the present case, there can be no question of the great advantage which is secured by an assessment under "B" in this kind of undertaking. The judgment has now been confirmed by the Court of Appeal.

THE AMATEUR FLOWER SHOW

(*Continued from page* 193.)

I AM glad to see flowering shrubs encouraged by giving them the next two classes, 14 and 15.

Many of the best kinds will have finished blooming, but where good collections are grown there should not be much difficulty in finding six or twelve varieties, and kinds may not be impossible. As no mention is made of hardiness we shall probably find some choice subjects from the climatically favoured parts of the country. The weather will play a part in the "timing" of certain species.

Watering will be almost certain to assist flower development and will be especially valuable shortly before the show.

The next group, cut flowers of herbaceous plants, will strongly appeal. A star indicates that bulbous and rhizomatous plants may be included. This will admit some of the choice lilums and irises.

Bulbs are readily obtainable now and no time must be lost in potting, if wanted. A frame will be suitable for them till growth is active, when a greenhouse would be best. Shade from strong sunshine is essential, also manure waterings when well rooted and green fly must be guarded against. It is doubtful whether any of the June-flowering irises will be left, but the lovely I. Kæmpferi should be in season. It is not too late to plant strong roots now in good rich soil, and when growth commences an abundance of water will be imperative to success.

The main point in most cases will be surface working of the soil, mulching, watering, thinning and staking where necessary.

Classes 18 and 19 are for pot plants grown under glass.

There is also a separate class for foliage plants only, but in the above classes both flowering and foliage plants are eligible.

There are separate classes for begonias, gloxinias, carnations and mimulus, but that does not, of course, exclude them from these classes.

Class 20 is for hardy annuals.

It is permissible to sow seed under glass. This should be a popular class. Sweet peas, clarkia, godetia, Lavatera, Sweet Sultan, lupins, cornflower and nigella are a few of the best kinds. Sweet peas have already been dealt with. The others can all be easily grown by sowing outside, though the difficulty of catching the soil just right for sowing, and the slug trouble, occasionally renders it desirable to sow inside. For this purpose a frame will do as well or better than a greenhouse.

Sowing outside is best done in a bed specially prepared in mid-April. At one time it was thought sufficient merely to scratch over the surface of the soil before sowing and to sow the seed thickly. Beautiful annuals deserve better treatment and the soil should be as well prepared as for other plants.

Thinning early, according to the possible size of the plants, staking and watering will constitute the essential attention necessary.

Orchids take the next two classes and the first will probably attract exhibitors who have noted collections.

The class for six plants will give the amateur who makes a hobby of orchids a chance to gain a coveted prize with his favourites. Such men are exceedingly keen and some good plants will certainly be seen.

Strong healthy plants are necessary to produce show spikes and blooms. Shade from strong sun, ample moisture to the roots and in the air, with judicious ventilation will do the rest.

Classes 23 and 24 are for carnations grown under glass.

These can, of course, be either perpetual-flowering, malmaison or border types. Perpetuals are almost exclusively grown now under glass. Plants which have been blooming since last September are not likely to supply the show flowers.

These will probably come from plants which were struck from cuttings inserted late last spring. Such plants, if pinched to make good

Digitized by Google

specimens, would begin to flower early this year and would continue well past the show date; strong layers rooted last August or September would also provide blooms at the right time. Such plants would have been kept in small pots till January or February and then potted into 5in. or 6in. pots and grown on under favourable conditions of temperature, ventilation, etc.

Cool conditions and partial shade from strong sun will be necessary from May onwards. Red spider, always liable to give trouble, must be kept at bay, and watering must never be neglected. Frequent weak doses of liquid manure water and soot and a little guano will add strength to spikes and substance to blooms. Amateurs who find any difficulty with the perpetual carnation should grow the border varieties. Layers rooted last August should be potted immediately, one plant in a 5in. pot or three in a 6in. Pot firmly, using a compost of good fibrous loam with a small portion of decayed manure and wood ash, and a sprinkling of soot and bone meal. If grown in a cool greenhouse, and proper attention paid to watering and disbudding, there would be every hope of obtaining good blooms at the right date.

Hardy pinks are allotted the next two classes. These are charming garden subjects and varieties are obtainable in fancy, self or laced forms, in addition to the Allwoodii group.

Pinks revel in sunshine and, like their relatives the carnations, prefer a loamy soil to any other, to which has been added lime and potash, the latter, preferably, in the form of burnt wood ash. Young plants set out this spring or last autumn, or older ones, should supply plenty of flowers at the right time.

Slugs are frequently troublesome and must be prevented from damaging the foliage. Liquid manure watering in May and June will be nelpfu!

Class 27 is for foliage plants in pots. There are numbers of fairly easily grown plants for this class. Choice, highly coloured kinds requiring stove treatment are not much grown now. The green foliaged kinds must be well shaded from sun and syringed freely, except some ferns.

Many highly coloured foliage plants require sun to bring out their richest colour, but Rex begonias and caladiums are exceptions and must be shaded.

Ferns take the next two classes. Except by a few specialists ferns are not grown nearly as much as they deserve. One of the most delightful exhibits at last year's Chelsea Show was one of ferns. The best time to examine ferns for potting or top-dressing is early spring. After this is done they delight in a shady, moist atmosphere with a fair heat until growth is completed. Clay's fertiliser is an excellent stimulant.

Classes 30 and 31 are for violas or pansies.

These are very popular and deservedly so. Cuttings struck last September in a cold frame will make ideal plants for providing blooms at the end of June. Older plants of violas may also be divided and planted now.

Partial shade from strong sun is desirable. All blooms should be removed till plants are growing freely, and after that, faded flowers regularly. Copious waterings will be essential if the weather be dry in June. In addition to an occasional weak liquid manure watering, two waterings, the first the last week in May and another ten days later, may be given by dissolving a ½ oz. sulphate of ammonia and ½ oz. superphosphate in two gallons of water.

Flowers should be thinned to one or two to each shoot. A rich soil must be prepared for the plants to be grown in pans, using equal parts loam, leaf-soil and manure, with a little bone meal and lime rubble. Strong young plants from last year's cuttings should be used, placing three in an 8in. pan. Grow in a frame, shade from strong sunlight, remove the lights at night, attend strictly to watering and remove faded blooms.

Antirrhinums are so easily grown and popular that there is likely to be strong competition for them in the next two classes.

Only strong central spikes will stand much chance of winning. Good plants must be ready for setting out in April. To obtain these the seed must have been sown not later than the end of January. Good garden soil will be suitable, but it must have a dressing of lime before planting. Plant firmly at a distance of 15ins. from plant to plant. Antirrhinums do exceedingly well grown in pots in a cool greenhouse; 5in. or 6in. pots are suitable.

Class 34 is for six pans of one genus of hardy plant.

This class gives the alpine lover a chance, and he will, no doubt, be the principal exhibitor. It is a bit late for many good subjects, but good collections may still be made.

Classes 35 and 36 are for gloxinias and begonias.

In many respects these require similar treatment. Bulbs must be started in March in gentle heat, either in boxes of leaf-soil and sand or singly in pots, a little larger than the bulb. When well started they should be potted on, the gloxinias into 5in. or 6in. pots, the begonias, especially single-flowered forms, will probably take 7in.; plants with double flower forms are not as a rule quite so robust. Compost must be good and should comprise two parts good fibrous loam, one part each decayed manure and leaf-soil. Gloxinias would prefer peat to leaf-soil. Shade from sun, plenty of moisture around the plants and in the air and a steady temperature of 55° at night, rising by day. As the plants begin to flower, drier and more airy conditions will be necessary. A close frame in June would do for the begonias. Flower buds should be picked off begonias till the middle of May. Frequent weak manure waterings should be given when well rooted. Avoid splashing the foliage of gloxinias with manure or soot water.

Large-flowered minulus take the next class. These flowers have come to the front rapidly this last few years. They are ideal plants for large or small gardens and easily grown. Cuttings rooted last autumn and kept on the dry side during the winter should now be growing freely and ready for potting. Older plants could be divided now or pieces of new growth taken off will root readily in a warm moist and shady position; 4in. or 5in. pots will be large enough for them. Minulus like a fairly rich soil and plenty of weak manure water as the rapidly increasing rootstock develops. A shady frame, kept somewhat close till flowering time will suit them.

Class 38 is for six fuchsias to be grown in pots not exceeding 6ins. in diameter. This beautiful old plant is not perhaps so popular as of old, but strongly appeals to many. It is a plant often grown well by the amateur with limited accommodation in the way of glass, and good plants are frequently grown in windows. As the size of pot is restricted, useful specimens rather than wonderful ones, such as were once grown, are expected. Cuttings rooted last autumn and kept quietly growing during the winter, will make ideal plants. Such plants will want their final pot in April. The best plants are those which form a good pyramidal habit without pinching, though it may be necessary to pinch side shoots once. Suitable soil would be, loam two parts, one each of leaf-soil and decayed manure, with sand and fairly firm potting. Shade from strong sun is essential and plenty of moisture at root, and before blooming commences a daily syringing of the plants. The plants may require a neat central stake and the side growths looped to it.

Class 39 is for six native British plants, to be grown in pans or pots.

Ferns would make a most interesting exhibit and vie with the exotic kinds and varieties. There are many good plants in the ericaceæ and leguminosæ orders, and hosts of others.

Whatever is grown it is generally advisable to follow conditions as to soil, sun, shade or moisture under which the plants thrive naturally.

Succulents take the next class.

Large collections of these interesting plants are found in many botanic gardens and also a few in privately owned gardens. Many amateurs grow a few succulents. It is astonishing how often one finds them in the garden where one or two greenhouses comprise the glass-house accommodation. I recently saw a fine specimen of the partridge-breasted aloe in a cottage window. This class will test their popularity. Exhibitors should put up as many species as possible in the space allotted.

Class 41. A group of flowering and foliage plants. This will not only be a test of skill in culture, but largely one of skill and taste in arrangement. Exhibitors should make certain whether the group is to be arranged against a wall or in the body of the hall, and if in the body of the hall, whether the group will be viewed from all sides. In the latter case more edging plants will be required, and a different style of arrangement to that of the group against a wall. It is not necessary to have all choice greenhouse plants. Annuals in pots should be included.

Class 42, and the last, is for the best new plant introduced into this country since 1914.

This is a particularly good idea and should bring forth a collection of plants such as will give the judges food for thought, and exhibitors and those interested in new plants a theme for discussion after the judging. ARTHUR J. COBB.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

NOTES FROM CONTRIBUTORS

THE HARDINESS OF GLADIOLUS PRIMULINUS.

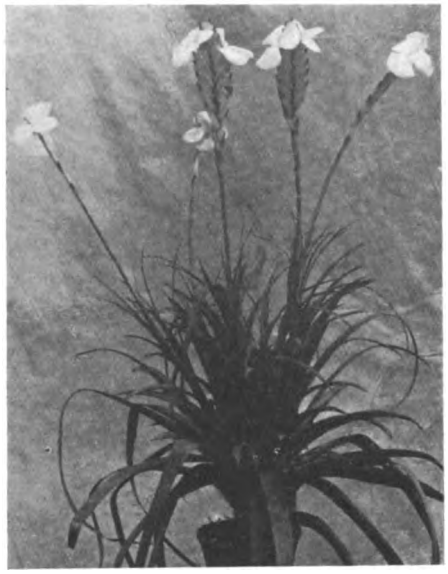
THE popularity of the gladiolus as a garden flower is increasing very rapidly, and the recent wireless talk upon it by Mr. W. J. Unwin is calculated still further to increase its adherents. It was a little disappointing, however, that the lecturer laid no stress upon the hardiness of Gladiolus primulinus and of the many florists' varieties with primulinus "blood." There is, I think, no doubt that the "prim" and "medio" varieties are more reliably hardy than the old Tritonia (Montbretia) crocosmæflora, and they are certainly infinitely hardier than the newer large-flowered "Montbretias." Many a clump of Tritonia crocosmæflora has perished because a jobbing gardener or handy-man has, in his enthusiasm for tidiness, removed the foliage in late autumn; but a clump of Gladiolus Orange Brilliant with the tops shortened (for experiment) to 3ins., and in a position subject to flooding, has, with me, survived the past winter without the least damage to corms or spawn, though both must have been *frozen in wet ground* on several occasions. The same clump withstood the winter of 1923–24 under exactly similar conditions, except that the withered foliage was not removed. Perhaps a dozen named varieties and a quantity of unnamed seedlings have been wintered outdoors in my stiff brick-earth soil during the past two years, and not a corm has failed to come through satisfactorily. Strangely enough, the then newly introduced Gladiolus primulinus is described in the Supplement to Nicholson's "Dictionary of Gardening" as a *stove* species!

Mr. Unwin, in his wireless talk, laid stress upon a light, rich soil as most suitable for gladiolus culture, but I think one can overdo the richness, and am sure that a fairly stiff soil suits them better. Twenty years ago, on a light, rather hungry soil which suited conifers and all kinds of shrubs "down to the ground," I could not grow gladioli so that they would increase satisfactorily, although, for experiment, I tried them in the rich earth of an onion bed. In some ground near by and on a lower level, of which the basis was a very stiff marl or marly clay, gladioli luxuriated. The primulinus hybrids are much hardier and increase far more rapidly than do the old "stiff-necked," large-flowered Childsii, nancianus and gandavensis strains, and may be expected to flourish in any decent soil which will retain moisture in summer; but that their preference is for a fairly stiff loam there can be no question. Good rose soil is good gladiolus soil also.

In comparing the increase of the primulinus and large-flowered sections, I am, of course, thinking of average varieties. A variety such as America would be difficult to surpass as regards ease of propagation, but America spawn will not flower the first season, as even pea-sized spawn of some of the "prims" often will, and these latter will reproduce themselves freely from self-sown seeds, if the gardener will allow a seed-pod or two to form.—R. V. G. W.

TWO HANDSOME GREENHOUSE PLANTS.

UNDOUBTEDLY one of the best plants for a warm greenhouse is Tillandsia Lindeni, introduced from the Andes of Peru in 1867. Tillandsia is a large genus of the Bromeliaceæ, but few species find favour with growers outside botanic gardens. The subject of this note is well shown in the illustration, the plant having five spikes of bloom. The first flowers open about Christmas time, and there are usually two blooms fully expanded at one time on each spike; as these fade others appear, and thus the flowering period is extended over three or four months. The colour is a beautiful shade of blue or bluish-purple, and they are exceptionally bright and cheerful during the winter



TILLANDSIA LINDENI, FROM PERU.

months. There is no difficulty in growing this plant and frequent re-potting is not needed. The rooting medium consists of peat and leaf-mould in equal parts, and ordinary flower pots or fairly deep pans are suitable receptacles which must be well provided with drainage. Fresh soil is given after the flower spikes are removed, and old plants produce a number of side shoots which can be removed and potted off singly.

In these days pancratiums and hymenocallis are not often met with, although they are well worthy of a place in the warm greenhouse or where a temperature of 50° to 55° is kept up. H. macrostephana produces sweet-scented white flowers, six to ten being formed in an umbel on a stalk 10ins. in length. The leaves are from 1ft. to 2ft. long. The illustration gives a good idea of the general characteristics of this useful plant, which

THE SWEET-SCENTED HYMENOCALLIS MACROSTEPHANA.

usually flowers in November and December. Frequent re-potting is not desirable, but when such an operation is deemed necessary, a good fibrous loam should be employed, with a little leaf-mould and sand added. Provide the pots with liberal drainage, and allow ample root space, then no more re-potting will be required for two or three years. H. macrostephana is a bulbous plant and the base of the bulb is planted just below the surface of the soil, and any necessary root disturbance should take place just prior to growth becoming active. The plants are kept more or less moist throughout the year, the greatest quantities being afforded when new leaves appear, which is immediately after the flowering period.—T. W. B., *Chepstow*.

POLYANTHA ROSES.

POSSIBLY nothing gives a better display throughout the whole of the summer months or for a longer period than polyantha roses. They are of very easy cultivation—all they ask is that the ground should be well dug, and very deeply, and then each year well fed. For beds hard pruning should be practised. The plants then make better growth and continue to flower for a longer period. Some of the varieties also make very pretty low hedges. For this purpose the stronger-growing varieties, like Orleans Rose (pelargonium pink), Edith Cavell (scarlet crimson), Orange King (the new orange sort) and Mrs. Cutbush (bright pink), are the most suitable. For beds the new Orange King (a bright orange with a tinge of salmon in it) is very beautiful, also Salmon Queen (another very beautiful new sort, bright salmon pink). Chatillon Rose is another very fine sort; it has trusses similar to the climbing American Pillar, and the colour is almost identical. Edith Cavell and Girlie are two of the best scarlet crimson sorts; for a good pelargonium pink, Orleans; Mrs. Cutbush, one of the originals, but still one of the best, for a good, clear pink; and Juliana, pale flesh, or better described as coral pink. These are the taller-growing sorts. For the very short-growing sorts, Ellen Poulsen (deep pink, very sweetly scented), Baby Tausendschön (a soft pink), Rudolph Kluis (a red form of Ellen Poulsen) and Greta Kluis (very similar to Baby Tausendschön but much deeper in colour) are the best. All these sorts make excellent short standards, and if grown on stems about 2½ft. to 3ft. high, help to make a most picturesque and ornamental bed. All the polyantha roses are very useful for pot culture, and are quite easily managed. They are constantly shown at the big horticultural shows grown in this way.—C.

BROCCOLI ALL THE YEAR.

THIS mild winter we have been able to to cut broccoli every week and to supply insistent demands for this fine vegetable. Success is entirely dependent on the weather, but a little planning is also necessary in order to have plants maturing in succession. Autumn broccoli, which come in after cauliflowers, are sown in the open in March. One sowing gave quite ample plants, but the transplanting was done at intervals, a few every week until sufficient were ensured. An improved Walcheren and Michaelmas White were the varieties. The last plant was cut in January. Winter kinds are generally more or less of a lottery, but not this year. Sown in April, we planted out in June and July, and we are still cutting heads yet. We rely mostly on the sprouting kinds, but this year Early White has been everything that could be desired—fine close heads, large size and excellent flavour. The spring kinds depend very much on weather, also, but we have fine plants coming on, tried and true varieties which seldom fail if given reasonable weather.

We would point out that broccoli must be planted firmly and given more space than cauliflowers.—CLYDESDALE.

SIMPLE GARDENING

STOPPING CHRYSANTHEMUMS.

FROM the early part of April to the middle of May it will be necessary to stop the leading stems of many varieties of chrysanthemums. The plants, in their normal growth form buds at the point of the shoot; in every case, at this season, those buds are overcome by growth shoots immediately below them, so that the latter grow and the buds shrivel. But the bud has done its work—arrested continual growth of one stem and thus caused several more to form. In the case of exhibition varieties and others that are required to bear blooms on given dates, stopping must be done. The stopping takes the place of the bud: it arrests growth of the main stem and causes several side ones to grow. Of course, only one shoot may be retained if this is desired, instead of three or more. Stopping, in the case of many varieties grown to form specimen plants, is absolutely necessary, as only a few are naturally free-branching enough to be grown on without it. Stopping does not mean cutting down, as it is done by merely removing the tip of the leading stem.

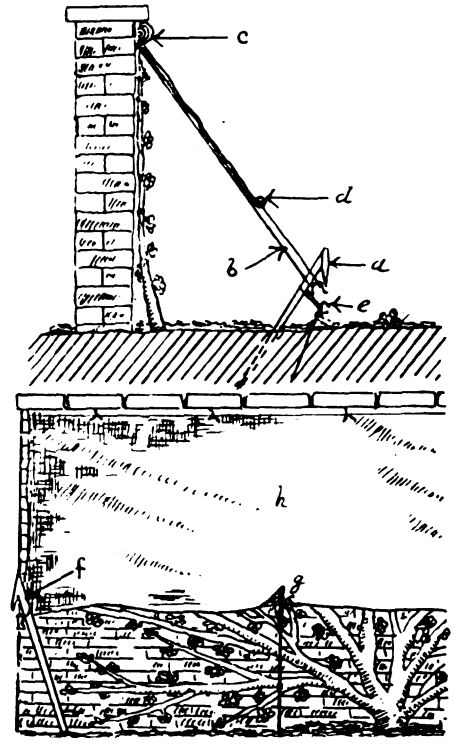
TYING DOWN VINE AND PEACH SHOOTS.

The amateur grape grower generally becomes enthusiastic in his work when young shoots appear and, also, the embryo bunches of grapes. When bunches can be seen in the points of the young shoots, even many experienced cultivators hesitate to remove any but the very weakest. But it is advisable to make up one's mind promptly and rub off, first the weakest and then the badly placed shoots at this early stage of their growth.

Healthy vine and peach shoots grow rapidly at this season and require very careful and constant attention. A cultivator who has not grown these fruits before may be very uncertain as to the treatment of the new shoots now. First, I will refer to vines. A young branch bears a bunch of grapes, sometimes two; the bunch nearest the main rod should be retained, the other, where there are two, pinched off. Then the branch itself should be stopped at the second or third joint beyond the bunch retained, so that by midsummer all roof space will be just covered, not more. The new shoots grow upwards towards the roof-glass, and it is necessary, except in lofty houses where special wire arrangements are made, to tie them down to the wires under the roof and 18ins. to 2ft. from it. This tying work must not be done at one time or in one day. With soft strands of raffia, tied about 6ins. from the end of the shoot, the latter should be depressed a few inches only to prevent the tip touching the glass. At intervals of a few days the shoots can be brought down to the wires safely. When the vines are in flower the final tying may be done. In the case of peaches and nectarines the most basal shoot on the present fruit-bearing branch should be neatly tied; others, on long branches, will require stopping where there is danger of overcrowding. This young basal shoot is an important one, as it will be the fruit-bearing branch next year and so take the place, probably, of the one on which it grows this year. Approximately, all new shoots should be tied at a minimum distance of 4ins. apart.

PROTECTING FRUIT BLOSSOM.

In many parts of the country the fruit buds are numerous on apple, pear, plum and cherry trees. The recent cold weather has had the effect of retarding the development of the buds, and so we may hope that the flowers will escape severe frosts. But whether plentiful or scarce, the blossom should be covered during the night-time and the early part of the day following night frosts. It is very important that the flowers be kept dry, as if slightly frozen while in that



condition less harm would be done than would be the case if they were wet when frozen. As far as possible, too, covering materials should be kept dry. This can be done by allowing them to dry before they are folded each morning. Wall trees are easily protected by using scrim or tiffany as shown in the sketches. It is not necessary to cover the trees from top to bottom; one-half or a little more being sufficient, as frost strikes downwards. About 3ft. from the wall drive in pegs 6ft. apart, shown at *a*, *b* is string holding securely the scrim, unrolled from *c*, at *d*. Under each long peg drive in a small one, *e*, to ensure additional firmness. The corner pegs should be driven in at a slight angle outwards, shown at *f*, and not upright, similar to the one *g*; then the canvas, *h*, will be held firmly against winds. Rough frames may be erected over small trees in the open quarters to bear up light scrim. A few evergreen branches, judiciously tied to the branches of bush-shaped trees, will afford protection. Herring nets, doubled, may be used in place of tiffany.

CUCUMBERS.

This note is intended chiefly for those persons who wish to grow their own cucumbers but have not had any practical experience. The plants thrive best when they can have a summer temperature and plenty of moisture; with expert treatment they can be grown in a very high temperature at express speed; but we are now considering the best treatment for them in warm greenhouses, pits and frames. The best compost is one made up of fibrous loam and half-rotted leaf-soil in equal proportions for the seeds and seedlings; the same for the growing plants, with rotted manure added. One seed should be sown in a small pot, the seed being placed flat and covered with 1in. of soil. Place the small pots close together in a propagating frame or a box on a stage and cover with glass. Careful watering is essential, else the seeds and seedlings will suffer. In a glass-house, heated, the bed should be made up one week prior to planting, to get the soil warm. The latter should form a bed 2ft. wide and 1ft. deep; the cucumbers being planted 3ft. 6ins. apart, trained to stakes and wires, and the ends pinched off when the main stem is 2ft. high. In frames, cucumbers succeed best grown in similar soil 1ft. deep on a hot-bed. The plants are allowed to ramble over the surface of the bed, stopped occasionally and surface-dressed as roots appear on the soil. Watch THE GARDEN for more cultural details in due course.

SOWING AND PLANTING ASPARAGUS.

Asparagus plants, well treated, are long lived, so it is well worth while doing all preparatory work as thoroughly as possible. In naturally sandy loams and where seaweed can be obtained as a surface dressing mixed with littery manure in the winter, very little trouble need be taken other than that entailed by weeding and feeding in July and August. In heavy soils beds should be raised about 6ins. and deep cultivation be the rule; but all elaborately made foundations for the beds are quite unnecessary. The surface soil should be thoroughly broken before seeds or plants are put in. Sow the seeds thinly in drills nearly 2ins. deep and at least 16ins. apart. Plants should be inserted 1ft. apart on tiny ridges, so that the roots may be spread out evenly, and covered with 3ins. of heavy, or 4ins. of light, soil. After planting or sowing, the surface of the bed should not be trodden down nor beaten with a spade. Overcrowded plants never present much sturdiness, and thus close planting should not be done. GEORGE GARNER.

UNSEASONABLE PRODUCE

THERE is a general belief that efficiency of transport is one of the main factors in the world's progress. There is no doubt that the speed at which produce from all corners of the globe is carried to this country has brought the gastronomic seasons together. This brings a constant influx into the British Isles of unseasonable garden and orchard produce, much of it at a price which is practically within reach of all pockets. By this I do not mean such fruits as oranges and bananas, which, although obtainable the year round, nevertheless have their origin in tropical or sub-tropical countries. Neither of them are capable of outside cultivation in this country, so they are by nature exotic. Rather do I refer to such flowers, fruits and vegetables as are in common cultivation in this country during their proper season, but are also supplied from abroad at times when the home-grown kinds are unobtainable.

They can be seen in any fruiterers or florists; and what a varied collection! Lilac from the South of France in January, artichokes from Brittany in February, plums, peaches, pears and nectarines from the Cape throughout the winter, new potatoes from Algiers in December, marigolds from the South of France in January, French beans from some place or another all the year round. This is only a selection. Many of them are of excellent quality, but I think it is safe to say that they are never so good as those grown at home. Home-grown forced garden produce, owing to its expense, has only a limited appeal and so is confined to a small public who like novelty, but this general importation, although useful, is not altogether satisfactory.

Surely much of our pleasure in our garden produce is that of anticipation. We look forward for days ahead to the first dish of succulent young peas from our garden. The smaller the supply the greater the pleasure. Even Brussels sprouts and cabbages are looked forward to at the beginning of the season. Towards the end even of the pea season the edge is taken off our appetite and we look upon them as a matter of course as an ordinary vegetable. Now, supposing that all the good things in vegetables and fruit are obtainable the year round, we shall not only become satiated with them, but our taste will be blunted. We shall no longer be able to masticate our peas with the same pleasure, in fact, all peas will taste alike to us. Most of the best things in the world come to London, but a plethora of goodness never made a man an epicure.

I remember at school being taught that the downfall of Rome was mainly owing to the banquets of nightingales tongues and other out of the way delicacies that became the fashion among Roman society; it would be a tragedy if historians a thousand years hence were to lay all the troubles of the present era to a sort of gastronomic effeteness.

ICE STORMS

Much as we may grumble at our climate, we have a great deal to be thankful for. Among other things we do not suffer from ice storms, which is a most unpleasant form of weather, for it always causes untold damage to trees. These storms are brought about by rain falling from a warm upper strata of air on to a belt of frost near the ground; the consequence is that every branch and twig is covered with a coating of ice which ultimately becomes so heavy that the branch cannot bear the weight and comes crashing to the ground; I have seen twigs three times their normal diameter from the great coating of ice surrounding them and thin grass stems enlarged to the size of candles. Apparently the latest town to suffer from such a visitation is St. Louis, where the damage done to trees has been enormous. I was in Boston in November, 1921, when the city experienced one of the worst ice storms on record. Although Boston suffered severely, it was nothing compared to Worcester, Mass. I went there on the next day and found hardly a whole tree standing in a town famous for its fine timber. I have forgotten the exact number of trees totally destroyed in the town area, but it ran into many thousands. These storms are usually very local in their action; for a few miles beyond Worcester there was a horrible scene of desolation with broken trees, telegraph poles snapped off, and wire lying tangled on the ground, while in the next valley, the moment we were over a small divide, conditions were quite normal. OLD-FASHIONED FLOWERS

THERE ARE NO SUBJECTS WHICH LEND MORE CHARM AND GRACE TO THE GARDEN THAN OUR OLD-FASHIONED AND TIME HONOURED FLOWERS.

IT is a matter for regret that so many old-fashioned flowers —fostered almost like children by our forefathers—should have been banished from our gardens, elbowed out by the introduction of new species, or varieties of those then existing in the belief that these later introductions were so much in advance of what had been previously grown. Probably, had they waited a few years before they took such a drastic step, many of them would still enrich our gardens of to-day. Cultural details of practically every class of plant grown are far in advance of what they were some sixty years or more ago, so it is more than probable that, had owners and growers retained these old-fashioned flowers for a time, many would have held a different opinion and given more attention to their requirements. So many had a charm of their own which is lacking in some of the flowers that are barring their return to the position and esteem they once held among flower lovers.

What about fragrance? There are many new species that lack that sweet perfume so predominant among those old flowers that adorned our gardens a decade ago. Take roses as an instance. It is true raisers are taking more pains to instil fragrance into the flower just now, but there are scores deficient of smell, and it is these that have ousted such good old varieties as Lamarque, whose pure whiteness and sweetness entitle it to a foremost place among climbers, thriving best on a warm wall. Then there are the moss roses, so frequently found in old gardens more than half a century ago, but now not half as much grown as their merits deserve. Besides Lamarque, just mentioned, there is another very old variety among the noisettes, Aimée Vibert, very fine as a pillar, its clusters of pure white blossoms, though small, commanding attention; it will thrive almost anywhere, in any position. For a good autumn rose what is better than that old Bourbon, Souvenir de la Malmaison, a large full flesh-coloured rose and very sweet; and many of the old chinas, also, supplied a wealth of flowers varying in colour from early April up to the end of the year. While speaking of roses it is well to mention the old yellow and white Banksias, whose clusters of small double flowers cannot fail to please. These require a warm wall and a light hand in pruning, as also does that very fine single rose bracteata, better known as the Macartney rose, white with showy yellow stamens, and flowering well into November. These last-mentioned varieties thrive and flower luxuriantly on a south-west wall at Bicton, East Devon. Yet one other I must mention, the old York and Lancaster rose, whose striped flowers enamoured our forefathers, yet it is rarely seen nowadays.

PULMONARIA, THE LUNGWORT, HAS ATTRACTIVE FLOWERS AND FOLIAGE.

It is very hardy and a most interesting border plant, full of vigour.

The dictamnus or fraxinella is one of the oldest inhabitants of our gardens and is a capital border plant, easily raised from

MULLEINS ALWAYS LOOK THEIR BEST WHEN FREELY GROUPED.

seed; perhaps the white variety is the best, as it is so useful for cutting, but the purple is very pretty and well worth growing. These are interesting plants, frequently alluded to as the "burning bush"—being smothered with a resinous exudation on the stems they burn quickly if a light be applied towards evening—and are excellent as an edging to a large bed or border of flowering shrubs.

The mulleins or verbascums thrive in any ordinary garden soil and show best when freely grouped. They go on flowering for a long period, while their showy flowers, mostly yellow, stand out well above the foliage: V. olympicum probably being the best, reaching 6ft. in height or more. Salvia patens, though but half-hardy, is a fine subject for summer decoration of the outside garden; its intense blue flowers call for special mention, but it is no use trying to grow it in poor soil, or the spikes will be very indifferent, but given good culture it is sure to please. Treatment as for the dahlia during winter is all that is necessary to retain the plants from year to year, and our gardens would be much enriched by a freer use of this very excellent sage. The dicentras—perhaps better known in the old days as dielytra—are charming hardy herbaceous plants, D. spectabilis being one of the best and a very old inhabitant, frequently termed

Digitized by Google

"bleeding heart" by the cottage folk and highly prized by many of them.

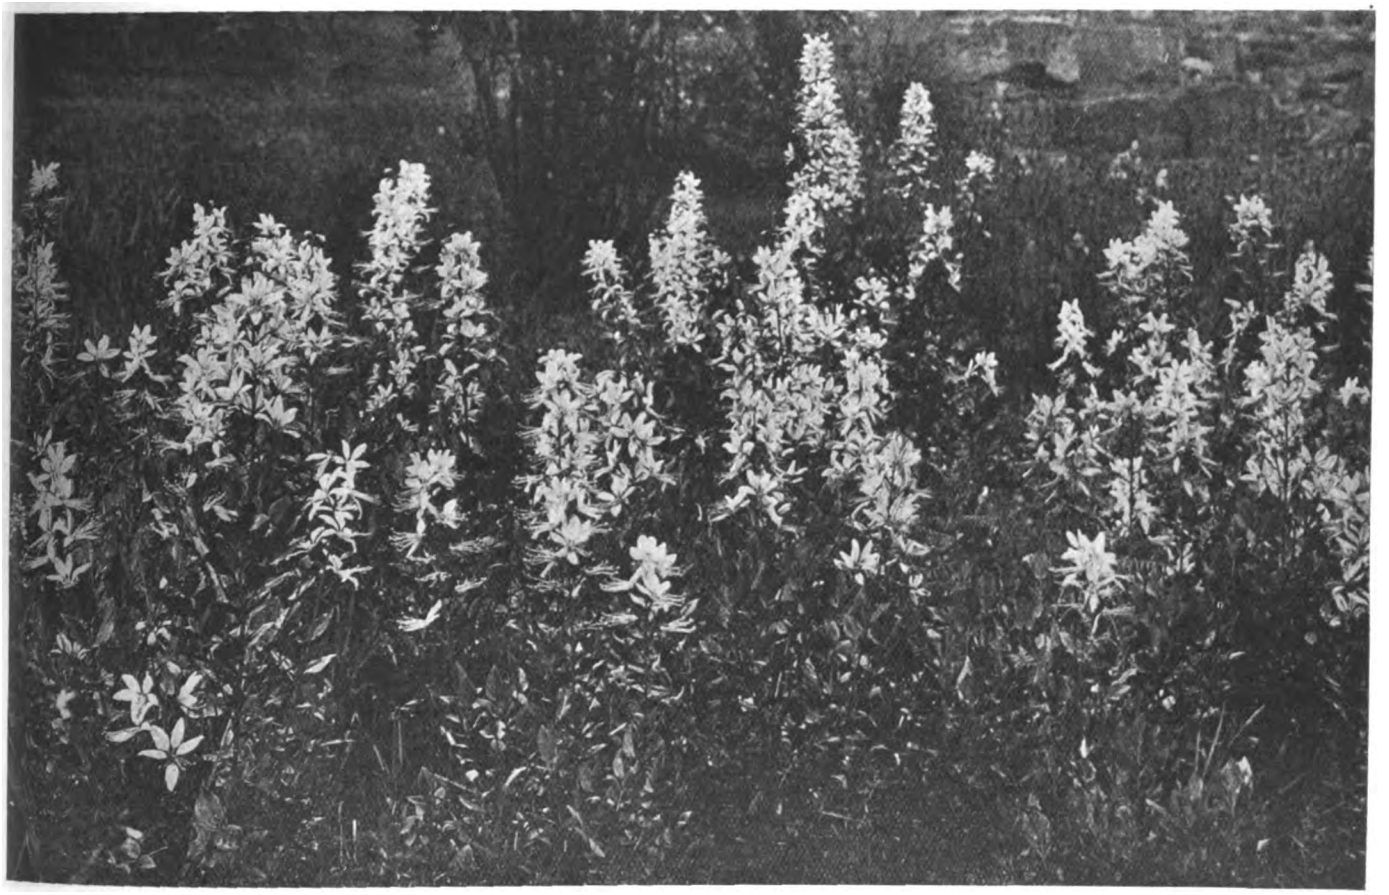
Lychnis chalcedonica was a special favourite long years ago with its bright scarlet clusters of flowers, long retained upon the plant, which added to its usefulness as a decorative perennial in our borders. Here again the newer varieties have almost driven it out of cultivation. Another old scarlet flower, Pentstemon Murrayanus, is now seldom seen, owing, no doubt, to similar circumstances; nevertheless, it was much admired and stood by us for many a year under fair treatment. Commelina cœlestis has a lovely blue flower—true, not very large, but freely produced on stems some 18ins. in height. It winters well in the ground in Devon and Cornwall. It has thin tuber-like roots similar to Salvia patens, and on its introduction over a century ago was grown under glass. The flowers and habit of the plant remind one of the tradescantias.

Among the Lily order few of us appear to have been able to cultivate so successfully as did our forefathers Lilium candidum, the cottage lily. We know of its presence in most cottage gardens of bygone years, but it is now rarely seen in good condition. The finest show that has come under my notice was of plants growing and flowering abundantly close to the stem of an old standard pear tree in Devonshire, with many of its healthy bulbs fully exposed to the weather and packed as tightly as a rope of onions; no transplanting or division had evidently been done for a number of years. My advice is, if they are doing well let them alone. L. candidum was introduced into this country as far back as 1596 and has always been a universal favourite, for the flowers are of the whitest and very fragrant.

Good beds of the old Persian and Turban ranunculus are few and far between compared with some thirty years back; the flowers are very beautiful and well repay the cultivator for any extra trouble spent in the preparation of the site and soil so necessary to ensure success. Thorough drainage 18ins. or so below the level of the soil, good loam, a little leaf-soil, and some well decayed cow-dung below planting level, will grow good flowers if tubers are planted in February. Hydrangea hortensis and its varieties are still with us, being long cultivated by cottage folk, and many a fine old bush can frequently be met with in the western counties, where they appear to thrive best, not being subjected to hard winters which kill the flower buds. For want of a better name—not knowing the correct one—cottagers often call them "changeables," on account of the flower heads changing colour. In Bocconia cordata, the plume poppy, we have an excellent foliage plant independent of the terminal panicles of creamy white flowers, which are produced in abundance when the plant is well grown. It is at home in a large bed among shrubs or in the herbaceous border among other perennials, but is far from being common in gardens. Malva moschata I grew largely in the herbaceous border nearly forty years back, finding it very useful for cutting. It grows some 2ft. high and is sweetly scented, but I have not come across a plant for some years now.

The tradescantias or spiderworts are worthy of more extended culture, the blue T. virginica and var. alba (the white variety) are to be found in quite small gardens around London, showing that it is a good town plant, but in the larger gardens it does not appear to have held its own. Another of the herbaceous order, Hesperis matronalis, which has long been a most valued garden plant, the old cottager evidently knew how to cultivate, as it was frequently found in a thriving condition. The flowers are very sweet and come early into flower. The double kinds are especially good for indoor decoration when cut. The surest method of retaining the stock is to propagate by cuttings in early summer. Plumbago Larpentæ gives us another blue flower—we have not one too many of such colour towards the end of summer. A sunny position suits it best, and the finest colony that has come under my notice was close to the sea in South Devon, hanging over a stone wall on a very dry border that held its roots.

We older folk can remember the bright patches in the border afforded by Monarda didyma. Its deep red flowers always attracted attention, yet now how seldom we find it given a place even among herbaceous plants, or, if we do occasionally come across it, there does not appear to be that robustness among them as of old. They thrive, though, in ordinary garden soil, but should never suffer for the want of



THE BURNING BUSH OR CANDLE PLANT, DICTAMNUS ALBUS, FORMS AN EXCELLENT BORDER.

Digitized by Google

moisture. Polemonium cæruleum and its white variety are good dwarf plants for the herbaceous border, and, though not showy, are interesting and likewise very free. Here the plant is known as Jacob's ladder to those with little experience in gardening matters. The variety himalayanum is well worth growing.

The hardy geranium (cranesbill) gave us a host of colours and is still to be found in variety where old-world flowers are admired. Growing in almost any soil and reaching some 2ft. in height, the Persian bellflower, Michauxia campanuloides, is a most interesting plant, but unfortunately does not appear to have a long life with us in this country. A somewhat elevated or dry position with a slight protection during winter gives it a better chance of pulling through, and I was particularly fortunate with its culture at Bicton.

Galega officinalis is another old garden friend. Free-flowering and useful for cutting, this blue and its white variety alba should find a place in the border; the foliage, too, is good, and it is altogether a desirable plant to cultivate. Pulmonaria, the lungwort, is valuable on account of its early flowering and its handsomely marked foliage with splashes of white. The plant is very dwarf, and has blue or white spikes of flowers. It thrives well in shady nooks, and it is a pity that it is not more frequently met with in gardens. In the old days it was supposed to be a cure for lung disease, hence the name lungwort.

Aconitum (monkshood) is a very old garden plant, yet it is only now and again that one sees it, although if left undisturbed it forms quite a colony, doing well in shady parts of the garden. It is easily increased by division, but no particle of root should be left about, as it is most poisonous. The alum root, Heuchera sanguinea splendens, is a really good front border plant with compact foliage, and the slender spikes of crimson flowers freely produced are valuable for cutting in early summer. Another evergreen plant, so valuable for mixing with cut flowers in large vases and yet seldom met with, is Ruscus racemosus, better known to-day as Danæ racemosa or Alexandrian laurel. It does not grow very tall—2ft. to 3ft.—but its finely cut long pendulous shoots are splendid for the purpose mentioned, and one can cut it indefinitely. J. MAYNE.

THE MODERN GLADIOLUS

IN reading an article written about sixteen years ago on the gladiolus, the following passage particularly interested me, "However great our enthusiasm for the gladiolus may be, we have to acknowledge that it can hardly be classed as one of the great flowers of the people—it just misses greatness." At the time this was written, it was no doubt perfectly true, it would also have been equally true of the sweet pea less than thirty years ago. The modern gladiolus does not, in my opinion, "just miss greatness," and I feel sure that if the author of my quotation could have foreseen the wonderful results which crossing and inter-crossing the various types or species (particularly the primulinus species) have given us, he would undoubtedly have prophesied a glorious future for a flower which apparently did not then impress him.

Perhaps a close interest and fairly wide experience in sweet peas leads me to compare the two flowers, which, although differing in structure, resemble one another in character. Both flowers are seen to their best advantage when cut and used for house decoration, both are easily grown, adaptable and reasonable subjects. Almost any kind of soil and situation will suit either, they are both inexpensive and embrace a remarkably wide range of colours and shades. The keen attention of hybridists has been, and will continue to be, attracted to the sweet pea and the gladiolus on account of their latent possibilities. Comparing the two flowers still further, we find the sweet pea scores with its lengthy flowering period of individual plants and with its perfume; on the other hand, we have the comparatively long time for which a bunch of cut gladioli will last in a fresh, clean condition.

In my opinion the gladiolus has now attained that stage in its evolution or development which the sweet pea reached about twenty years ago and one can confidently predict a sharp rise in public esteem for the former without fear of serious contradiction or any undue stretch of imagination.

Just what measure of popularity the gladiolus will eventually attain, will depend mainly on the extent and rate of progress as regards improvements in form and colour. Of late years, progress in these directions has been rapid, and a very great many new varieties are each year being put on the market. There is, and will be, an increasing temptation to place novelties in commerce that are little or no improvement on existing kinds, just as in the case of other popular flowers—roses, sweet peas, etc. I sincerely hope raisers will endeavour to avoid this sure source of disappointment to growers, which is more serious in the case of the gladiolus than in almost any other flower. A sweet pea novelty at 1d. or 1½d. a seed is quite a different proposition from a gladiolus novelty at £1 or 30s. a corm.

Gladioli have been grown in this country for hundreds of years, and I expect there have been articles in THE GARDEN about them ever since it was first published, but from what I have observed, I feel sure the general flower-loving public here is only just becoming aware of their real value. In this respect, the Americans and Canadians are ahead of us; but when the ease of culture and the amount of pleasure the gladioli give in the house is fully realised, their popularity will rival that of the sweet pea or the carnation.

Most of my readers will be aware that there are many different species of gladioli, mostly of African origin, but these have been intercrossed to such an extent that it is perhaps impossible to classify all modern varieties under their respective sections. We need only concern ourselves with two types, both autumn-flowering, *i.e.*, the large-flowering hybrids and the primulinus hybrids. These differ among themselves in the size, shape and placing of their flowers; but, generally speaking, the large-flowering hybrids have large, bold, wide-open blooms, arranged in a double row facing one way and placed fairly closely together on long, stout stems. The primulinus hybrids have smaller flowers, spaced farther apart on thinner stems, which are, however, wiry, quite strong, and in keeping with the size of the blooms.

Each of these types makes a different appeal to the flower lover. While there is something grand and stately, almost massive, in the splendour of the large-flowering varieties, the "prim." hybrids are light, graceful and so very dainty. One would use the large-flowering for decorating a church or in large vases and baskets for the hall or fireplace, but where a lighter effect is necessary, the "prims." excel. For table decorations they are really exquisite. Last season, I was not surprised to notice several first prizes carried off by "prims." in keen competition against such flowers as roses, sweet peas and carnations in strong table-decoration classes.

I hardly like to attempt to give a word picture of the colours which are now found in the gladiolus, one has to see them to realise their beauty, so clear and clean, and not a bit harsh in tone. Whites, creams, yellows, orange, salmon, lavender-blue, purple, rose, pink, scarlet, blood-red, nearly black, and innumerable attractive colour blendings and mixtures of two or more shades. In the primulinus hybrid section are found quite different colour tones, most of them true art shades: Oriental tints would, perhaps, best describe them. I had never seen such glorious salmon and orange shades before I knew "prims." It does not seem to matter whether one variety or a dozen are used in the same decoration, for they all harmonise so beautifully. I readily grant that some combinations blend better than others, but it is really a difficult matter to arrange any decoration of primulinus hybrid gladioli that will offend a critical artistic taste. It is easy to strike a colour discord with most other popular flowers that is as perceptible as a flat iron dropped on the piano keys. Another point in favour of the gladiolus lies in the fact that it rarely clashes with modern room furnishings, whatever may be the prevailing colour, and most varieties are also excellent under aritficial light. No foliage other than their own is necessary to produce a pleasing effect and no flower is easier to arrange artistically.

I should most probably repeat what others have previously written in these columns if I described in detail the origin of the primulinus species, so I will just mention for those who may not know, that this small yellow gladiolus was found about twenty years ago on the banks of the Victoria Falls, South

Digitized by Google

Africa. Unlike any other species, its upper petals are bent over, forming a kind of hood, or umbrella, which botanists tell us was to protect the fertilising organs from the misty spray of the great waterfall. "Maid of the Mist," as it was aptly named, when hybridised with the larger-flowered types, released for our pleasure a beauty of colouring in its progeny transcending all previous introductions. It is no exaggeration to add that "Maid of the Mist" has raised a "possible" to a "probable" flower, it has put the GLAD into "Gladiolus."

The flowering period is lengthy and a judicious choice of varieties will give a wealth of blooms from mid-July until well into October. Probably I shall not over-reach the mark in saying that modern gladioli are as exquisite as orchids, yet as easily grown as mustard and cress. CHAS. W. J. UNWIN.

NOTES ON SOME VIBURNUMS

AS a genus the viburnum is not enough grown. This may appear to be a strange remark considering the fact that practically every garden has a fine bush of V. Opulus or V. plicatus, but it is true all the same. There are about thirty species which are hardy in the British Isles, and they are all of easy cultivation. I know of no genus of shrubs or trees whose general excellence is so great, combined with variety of form and shape. Perhaps a few notes on my experiences with this genus may be of interest to readers of THE GARDEN.

I had better begin with what I consider to be a blot on the excellence of the genus as a whole. This is V. rhytidophyllum. I know that this plant is much praised by Mr. Bean and other experts in shrubs, but I do not agree with their judgment in this case. It is an evergreen shrub with large umbel-like trusses of flowers and red fruits turning to black when they are ripe. I do not find fault with the habit, flowers or fruit, but only with the foliage. At the best the leaves are dowdy, unpleasantly wrinkled and of a dingy green. In the winter they have an ungainly habit of flopping straight down, as if the plant was in the sulks, while they are so easily torn and damaged that unless in exceptional circumstances they look moth eaten at all seasons of the year. Why this plant should be so lauded while others infinitely more valuable are passed over is beyond my comprehension.

A fine species that should be more often grown is V. Henryi. This is also an evergreen with narrow, pointed, dark shiny green leaves, which stand out well from the branches and so are an attraction throughout the year. I have several plants from 4–5ft. in height which are always a pleasure to look at. The flowers are pure white and, although small, are carried in large panicles. The fruit is oval and turns from red to black. It is said that it is sometimes a shy fruiter, but I find that the more exposed the plant is the more it fruits. On the east coast of Scotland my best fruiting plant is on the top of a dryish bank where it is in full sun and is in a draughty position.

Next to it is a plant of V. utile, which I consider one of the best of the whole genus. It is more twiggy than V. Henryi, and the twigs shoot off at odd angles, making the growth most attractive. The leaves are not so long or so narrow as in V. Henryi, and are of a lighter shade of green, although just as glossy, while the undersurface is almost white. The white flowers are borne in May on well rounded trusses, while the buds have a pink tinge. The fruit is blue-black. V. utile, I find, is a shy seeder even in a plant 4ft. high.

Another useful viburnum is V. Davidi. This is an evergreen shrub always of low, compact growth, and is noticeable for its leaves, which are large, averaging about 4ins. in length and 2ins. in width. They are smooth and dark green in colour, and are conspicuous for the three large veins which run longitudinally. The flowers are tiny and, although carried in large heads, are uninteresting. When it fruits abundantly the blue fruits are attractive. One of the advantages of this plant is that it never gets out of hand, so its attractive form and foliage are useful in small borders or under a low window. I have two plants, one on each side of the door outside a low greenhouse, and this appears to be an admirable position for them.

Apart from V. Opulus and V. tomentosum and their forms which are so well known, by far the best of the deciduous viburnums are V. Carlesii and V. fragrans. Although some people agree with me that V. fragrans is the better plant of the two, most gardeners so far seem to prefer Carlesii, the reason I think being that V. fragrans has to be some size before it flowers at all freely. V. Carlesii is a much smaller plant and appears never to exceed 4ft. in height. With me it is not such a good grower as fragrans, and is inclined to straggle,

THE DARK BLUE FRUITS OF VIBURNUM DAVIDI.

or rather it appears to have too few branches and so is open in habit. Fragrans, on the other hand, will grow into a large bush and is a very quick grower. Cuttings struck in 1919 are 5ft. in height, and one of the original plants which germinated in 1915–16 is over 7ft. and is 5ft. through. The great advantage to my mind of this plant is that it flowers from the New Year to the end of March. It has stood 16° of frost in my garden without turning a hair. There are two forms, pale pink and white, and there is nothing to choose between the two. This plant is extremely easy to propagate from cuttings. I have not yet fruited fragrans, nor have I ever heard of a good crop of fruit in this country; perhaps the reason is that there are no insects about at the time it flowers. Farrer spoke of it as very pleasant to eat.

I have a number of other species coming on, but they are not large enough to judge their position in this most useful genus. One which has not yet flowered with me is V. hupehense. From the description the fruits appear to be larger than most of them. It has, however, an attractive growth, more willowy than any other viburnum, at least in its young stage, and I should think is going to prove a very useful plant for our gardens. Another which seems to break into foliage very early in the year is V. lobophyllum. This has round red fruits, and belongs to a group which is rather confusing and of which the best known member is V. dilatatum. E. H. M. C.

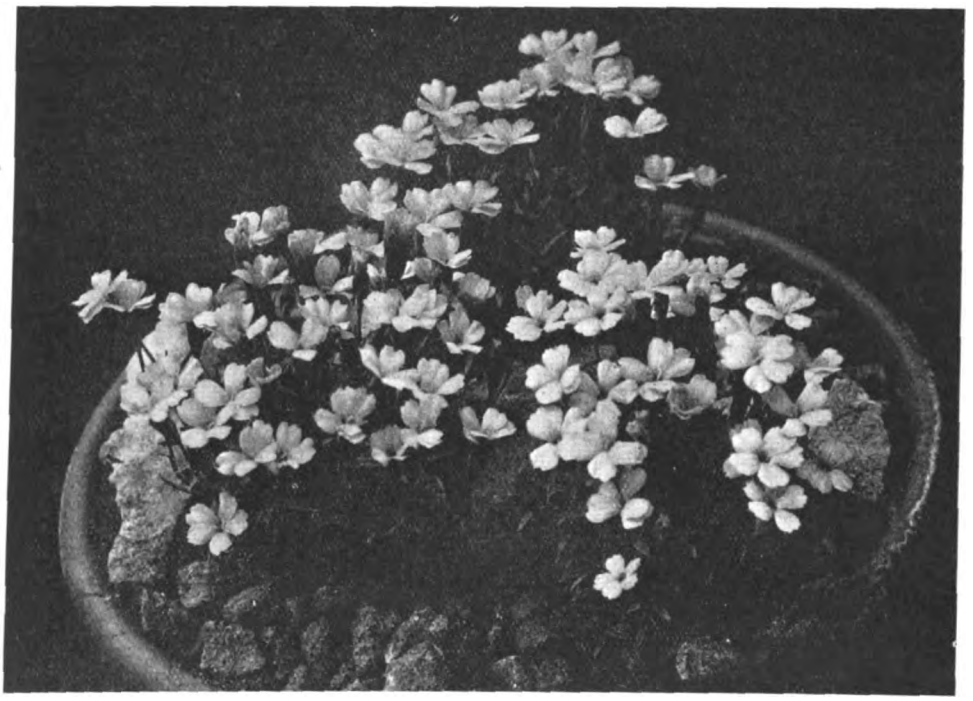
ALPINE PLANTS INSIDE

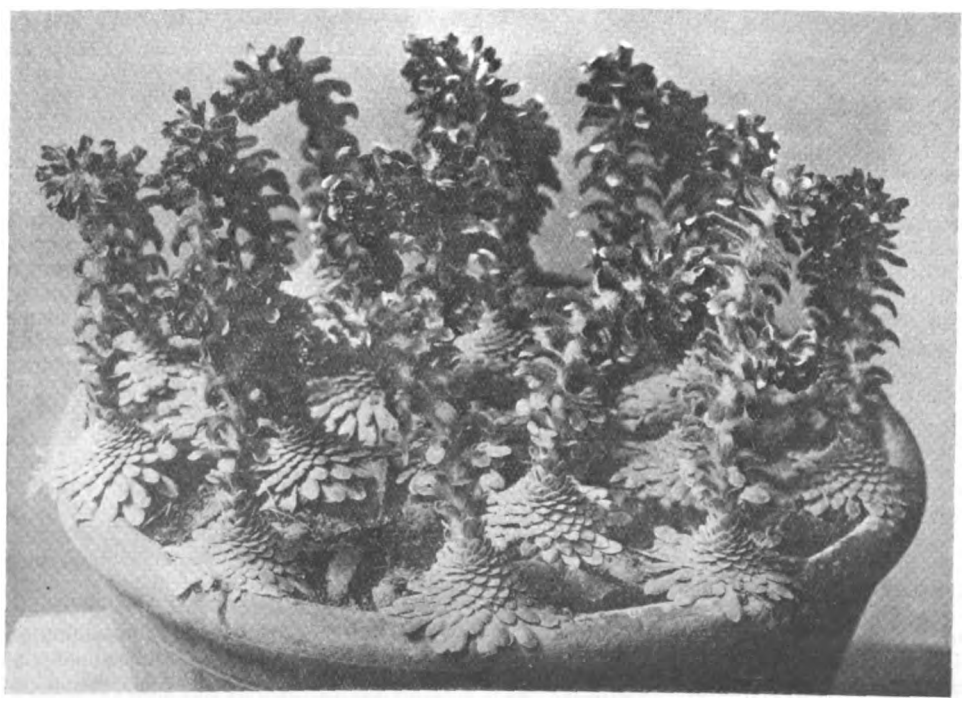
AS MR. MARK PENWICK HAS SHOWN AT VINCENT SQUARE, THERE ARE NO PLANTS WHICH EXCEL SO MUCH AS ALPINES IN GIVING A FINE INDOOR SHOW IN A SMALL AREA.

AS it is impossible to deal exhaustively with the above subject in a note of this kind, it will be readily understood that even essentials must necessarily be comparatively brief, consequently rather incomplete, nevertheless an impartial survey may serve some useful purpose. Seeing that I have in mind two distinct kinds of alpine houses and two wholly different methods of achieving a somewhat relative end, both are so widely variant that each must be dealt with separately, lest confusion arise. The theme then of my present discourse will be the most unnatural of the two extremes, that is the culture of mountain plants as specimens in either pots or pans.

The primary object of any alpine house should be the accommodation of such plants which for various reasons, principally climatic, require the shelter such a structure affords in order that the fulness of beauty can be obtained without all sorts of perplexing problems and setbacks inseparable from the cultivation of many choice rock plants. Apart from these, a great number of others are much improved when treated as pot specimens and successfully grown in the confines of a cold house. Yet again, there are others that require to be frequently divided or otherwise propagated if they are to be of any decorative value. It may be added here that many plants of unsurpassing beauty in the rock garden are practically worthless for the purpose referred to. The essential point therefore is to concentrate on those kinds that are known to respond to this unnatural yet congenial treatment. The minute details of cultivation are numerous. Space only admits of a few of the most important being collectively and lightly touched upon.



DIANTHUS MICROLEPIS, COMPACT IN GROWTH AND OF EASY CULTURE.



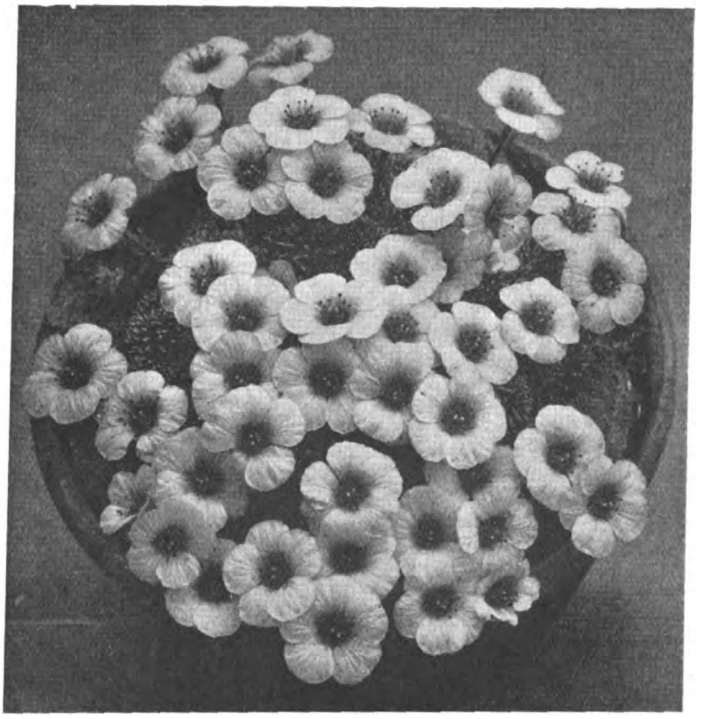
THE GRACEFUL SPIKES OF SAXIFRAGA GRISEBACHII, WISLEY VAR.

It will have already been gathered that an alpine house should be light and airy, no artificial heat being required for raising the plants. Coddling at any time will prove disastrous both to the characteristic charm of foliage and sturdiness of flower. The work of re-potting as a general rule should be done after flowering is past, but there are many exceptions to this rule; forethought in these matters is always necessary. Perfect drainage must be provided in all cases. Watering, too, is one, if not the most, important item connected with good culture, yet it is too often looked upon lightly. Attention to all other matters will be of no avail if this be neglected or not carried out with proper care and understanding. The point is to give, and give freely, whenever water is required, but only when. Naturally, during autumn and winter, watering will become less frequent and should never be undertaken during frosty periods. Some varieties of the Kabschia group of saxifrages when allowed to become too dry in the above-mentioned seasons, often rush off during mild spells into premature growth when otherwise they would plump up for flower. Overhead waterings should be avoided generally, though at the proper moment an occasional spray refreshes most plants. This brings me to suitable soils.

Three different mixtures will suffice to cover the field in a general way, though in various cases and with some individual plants some modification of the following composts may be necessary. The unwary should be guided by the soil plants are growing in when purchased, remembering that after the first stages of growth potting soils must be less fine, yet quite free. Compost No. 1.—Three parts fibrous loam, one part half decayed leaf mould and half part sharp sand or grit. No. 2 is formed by adding to the above mixture fully half part lime rubble or limestone chips. No. 3 consists of

Digitized by Google

two parts peat and one part light loam and half part sand. To append a list of suitable plants is a perplexing problem, so numerous are they that one would almost hesitate before committing themselves to a short selection, but to exclude such a list would defeat the object uppermost in my mind. As catalogue numbers are impossible, fifty shall be the limit, that is if the Editor permits. By omitting mention other than here of many campanulas, primulas, bulbous plants and a whole host of others that can be grown on in cold frames or kept plunged outside until their prospective flowering season, when they can be brought in to swell the existing floral display or form drifts of colour during dull periods, I shall be able to include more of what might be appropriately termed permanent occupants.



SAXIFRAGA FALDONSIDE COVERED WITH YELLOW FLOWERS.

List No. 1.—Acantholimon venustum, Androsace cylindrica*, A. helvetica*, A. imbricata*, Armeria cæspitosa*, Asperula arcadiensis, Astragalus monspessulanus, Convolvulus nitida, Daphne rupestris, Dianthus microlepis*, Draba dedeana* Edraianthus Pumilio, Erodium chamædryoides*, E. corsicum, Erinacea hispanica, Genista Villarsii, Geranium argenteum, Haberlea Ferdinandi Coburgi, H. virginalis, Lewisia Howellii, L. Tweedii, Morisia hypogæa, Pelargonium Endlicheriana, Phyteuma comosum, Primula marginata, Saxifraga Boryi*, S. cochlearis*, S. Dr. Ramsey*, S. Faldonside*, S. Grisebachii Wisley var., S. hybrida H. Marshall*, S. luteo-viridis, S. longifolia*, S. lilacina*, S. Myra*, Sedum Palmeri, S. spathulifolium*, Sempervivum arachnoideum*.

List No. 2.—Chiogenes serpyllifolia, Conandron ramondioides, Diapensia lapponica, Ramondia serbica, Rhododendron chamæcistus, Schizocodon macrophylla, Shortia uniflora, S. uniflora grandiflora.

With a few exceptions plants in List No. 1 thrive well in compost No. 2, and List No. 2 in compost No. 3. Plants marked with an asterisk are most suitable for pans while the remainder are for pots.

In conclusion let me add, a well appointed alpine house compares very favourably with other less simple and more expensive forms of indoor gardening. For this reason alone it should appeal especially to small amateurs who may not find it possible to satisfy their more cherished ambitions in the outdoor garden, and to whom the question of expense is important. J. T. H.

BULB NOTES

CROCUS VITELLINUS.

LAST autumn I was in the happy position of being able to exchange books with my good friend, Mr. E. A. Bowles. "Hardy Bulbs" went to Myddelton House and "Crocus and Colchicum" came to Whitewell Rectory. I had just got a few new crocuses from van Tubergen of Haarlem, including some vitellinus. This firm and our own Barr and Sons of London I look upon as crocus specialists. Imagine then my surprise when the newly received bulbs flowered to find that they did not tally with Mr. Bowles's description. I sent some to him to ask what they were. The reply came, "What a funny thing writing a book is. You have no sooner put down all you know than up jumps a new fact. That crocus of yours is vitellinus right enough. I nearly jumped out of my shoes when I saw one of this straw coloured form among mine the other day." He went on to say that his came in a newly collected lot from near Jerusalem and suggested that Tubergen got his from the same locality. It is a very charming soft straw colour and a great contrast to the usual orange. I am sure I could soon get as fond of crocuses as a mouse. By the way, I suppose the corms of the different species have each of them a flavour of their own. How else can one account for mice always going for Sieberi in a tray which was partitioned off into receptacles for Imperati, susianus, Sieberi, biflorus and Tomasinianus? Every time it must have been Sieberi, for none of the others were touched.

ERANTHIS TUBERGENI.

This newcomer received an award of merit at Vincent Square last year. I have now a few of my own and have been able to observe it at close quarters with the old Winter Aconite (E. hyemalis). It has much larger flowers and they are of a deeper yellow. Then, whereas hyemalis measured an inch across the top, Tubergeni was an inch and a quarter. Barr, who catalogues it, says it is a great advance on the old variety. So it is, if only it proves itself to be as good a doer and as unfastidious about soil and situation as my short trial suggests it will be.

POETAZ (NARCISSUS) EARLY PERFECTION.

If my one season's experience is not wholly misleading, I struck oil when I bought some bulbs of this variety last autumn, knowing little more about it than its price. It was said to be early flowering, but as such a description is, after all, only relative, an ounce of experience is worth its weight in gold in determining its practical value. Potted on the same day and grown all along side by side with some of its poetaz relations and a pot of the old polyanthus narcissus — Mont Cenis — in a cool greenhouse, this newcomer was in flower nine or ten days before any of them. This alone gives it a special value, which is certainly not diminished when its long, stiff stems and its numerous good-sized shapely flowers are taken into consideration. They remind me very much of Alsace in their colouring, but whereas that variety has not often more than three flowers on a stem, Early Perfection has from five to eight. I wish I had happened to have had some Alsace this year for comparison, as I believe it is the earliest of the original poetaz under glass. I think, however, in racing parlance, it would have been included in "the rest, nowhere." Mr. van Tubergen, from whom I had the bulbs, tells me he knows nothing about its origin except that it is a Dutch seedling which has made a great name for itself by its earliness. Its appearance suggests a polyanthus-narcissus as its mother and not a poet as was the case with all lucky Mr. R. A. van de Schoot's original varieties. I often think what a happy and profitable inspiration that was which came over my friend when he was one day walking in his bulb fields, "Why should I not try polyanthus pollen on a poeticus variety? I don't think this has ever been done." Old friend Time is continually adding to the original varieties and giving us a wider range of choice. Some of these, like Orange Blossom and Orange Cup, are very attractive. Mr. Clarence Elliott, when

Digitized by Google

he is not trying to convert sinks and pig troughs turns his attention to the making of big rock gardens. To his presence at Shrewsbury for this purpose I owe his surprise visit last year, when I had a few nice ones in flower. They were new to him, but he showed his appreciation by begging for a few blooms to take back to his wife who was with him there for a few weeks while the work was in progress. Why this aside? Because the opinion of a non-specialist who is accustomed to go about and see things, is always valuable. These new poetaz might well be more widely known and grown.

SHORT STEMS ON EARLY TULIPS IN POTS.

The Editor would be doing a whole crowd of us poor people who have to have greenhouses which can never boast a temperature of more than about, say, 50° F., and who have no means of heavy shading growing bulbs, if he could get someone who has himself done the trick to tell us how we can get decent stems on early-flowering tulips in the third and fourth weeks in January or even in early February. I am disposed to think it cannot be done. Our efforts here are miserable failures in almost every case. There are one or two exceptions. The white Diana is one. I have never grown it until this winter; so it was a pleasant surprise to have a decent pot of it in flower on February 5th. What about the others? With sufficient heat and facilities for very heavy shading and some bottom heat wonders can be worked and the Editor makes our mouths water when he tells us how he buys bunches of nice tulips in January with stems long enough to "cut an inch or so off"—but can such stems be produced in any sort of a greenhouse short of a stove? I am watching my two or three "Mendel" varieties with sanguine expectancy.

POTTING FREESIAS AND PLUNGING.

I read an article in a contemporary recently in which the writer advocated plunging the pots, when the bulbs were first planted. My good friend Mr. G. H. Dalrymple, who has the eye of a hawk for anything that appears in print on the subject of freesias, has taken the writer to task this week. He states he has grown thousands and never has plunged one. So have I, and I, too, have never plunged one. There is no necessity whatever for such a practice. It must be very bothering if it is attempted, as, in favourable circumstances, the fresh growth appears in a very short time and a perpetual series of scratchings down to the top of the pots would have to take place to know when they must be taken out. It is just as well this should be said now when the freesia season is in full swing. Mine began far too early this year. The house which we always knew was our warmest and where only a few odd pots used to go, was three-quarters filled with freesias this year. It must be warmer than we thought. The thermometer has probably underdone the temperature in the past. At all events the whole of those in this house have suffered inasmuch as the stems were weaker and more sappy than they ought to be, and the flowers did not last as long as they usually do when cut. Even that fine Dutch variety Apotheose displayed a weakness in its usually stout stiff stems. I feel pretty sure that all coloured varieties are all the better the cooler they are grown. As these are increasing in favour with flower lovers I feel this fact ought to be known. They do not bear, as far as my experience goes, the same treatment as the old refracta alba.

FREESIAS FROM SEED.

A big firm has taken the bull by its horns and given a prominent place in its 1925 Seed Catalogue to freesias from seed. Messrs. James Carter and Co. have a coloured plate to show their customers the sort of flowers they may expect to get from sowing the seed they offer. It is not in the least exaggerated. Given a first rate strain, good results are as certain to follow as night follows day. The point that is troubling me at present is the time when we may expect to see them bloom. Freesias can be flowered in seven or eight months from the time the seed is sown, but whether this will be found to be a practical working proposition I cannot say. I have my doubts. My own experience points to January or February as being the most promising time to sow if quick results are required, but longer experience and more information are needed to settle the question.

DWARF IRISES IN POTS.

For those on the look-out for something rather out of the common to grow in a very cool house, may I suggest a trial of these four little fellows, Histrio, Vartani, Sindpers and reticulata. They can be had in full bloom at the end, or even the middle, of January in a greenhouse just one remove from a cold house; and if they are grown in small, round pans or low pots, make a welcome change from the usual run of early forced bulbs. Histrio, Vartani and Sindpers have pale blue or grey flowers, and reticulata rich purple. JOSEPH JACOB.

THE USES OF GARDEN NETTING

AT this season of the year netting can perhaps be described as one of the most useful of all garden sundries. To many gardeners the use of this valuable commodity is confined almost entirely as a means of protection from the depredations of birds among the young and succulent seedlings now appearing in most kitchen gardens. There can be no doubt that when stretched over suitable supports this forms an ideal method of safeguarding growing plants and ensuring successful crops at the appointed time; while its value as a protection for growing fruit from birds, wasps, etc., will be readily admitted. Take a walk through any fruit garden during the early part of spring, and one immediately notices the tremendous fascination which young opening fruit-buds have for most of the feathered tribe, although it is only fair to the birds to state that the fruit buds are usually destroyed by birds in pursuit of insects. While it would not be practicable to enclose every tree in a casing of netting, the majority of dwarf and wall trees can be very easily and satisfactorily protected from marauders. If a fine-meshed netting can be hung on supports fixed either to the wall or round the tree in such a manner that it hangs quite clear of the tree itself, it will in no way damage the bloom or interfere with the growth. A protector of this nature will not only render the tree immune from birds, but will also serve to ward off frost and act as a decided break to cold, rough winds. Visitors to recent R.H.S. shows will have noticed the exhibits of both Major C. Walker of Brecon and Messrs. House and Garden Sundries, each of which prominently featured various methods of protection. Major Walker's appliances are solely designed to render growing fruit immune from birds, frost, cold winds, wasps, etc. They consist principally of a fine-meshed netting which is supplied complete with the necessary supports for simple fixing. They have the great advantage of being portable, and can be erected in a few moments by one man. The specialities of Messrs. House and Garden Sundries consist mainly of stout wire supports and frames, manufactured in various sizes, for protecting seed-beds, plants or wall trees. The supports are simply placed in position on the wall or in the ground, and the netting, when fixed over them, forms a complete cage. These contrivances are extremely simple to erect, and when finished with can be taken down in a few moments.

For the training of peas, beans, sweet peas, etc., netting is also extremely useful, inasmuch as it can be taken down and stored in a small space when the plants have finished yielding. For this purpose it will usually be found that a netting of larger mesh and stronger manufacture will be required than is used in the foregoing. An ideal netting for this purpose is that known as the "Simplicitas" brand. It is made from a special strong cotton cord and is far superior to the majority of ordinary nettings on the market, which are usually made from hemp. The writer has had a quantity in regular use for the past five years and it is still as serviceable as when first used. This is all the more surprising when one considers that it stood the test of two winters in the open without shelter of any kind from the weather. It can also be obtained in cylindrical lengths of various diameters, and in this form is particularly useful for supporting clumps of herbaceous plants or for training circular clumps of sweet peas, etc.

Old fishing nets are seldom, if ever, satisfactory, and usually give more trouble in fixing and repairing than they are worth. The additional expenditure of a few extra shillings in this respect is

Digitized by Google

usually well worth while. An interesting innovation of recent years is the creation of a string netting department at St. Dunstan's, where many of the blinded ex-soldiers and sailors have been trained in the manufacture of all kinds of nets. The industry has become so well established that at the present time it gives employment to about five hundred of these men in their own homes, and readers might well bear this in mind when ordering nets for the coming season. J. C.

EASTER FLOWERS AT VINCENT SQUARE

QUITE a gay and festive scene met the eye on entering the Royal Horticultural Society's Hall at Vincent Square on the occasion of the usual fortnightly meeting on April 7th and 8th last. The special exhibits of odontoglossums probably took the premier place; while roses, narcissi, carnations, alpine and stove plants and shrubs all added their quota to the welcome display of colour and bloom. Cinerarias and primulas were also represented, massed in groups forming a many-coloured carpet. The daffodil season is a late one this year, and many exhibits are being reserved for the Narcissus Show on April 15th and 16th. Fruit in the shape of home-grown apples in season was in the capable hands of Messrs. Bunyard of Maidstone. The proximity of Easter no doubt accounted to some extent for the small attendance.

One of the main exhibits of primulas was that put up by the Mental Hospital, Napsbury, St. Albans (gardener, Mr. W. J. Jennings). The exhibit consisted of hybrids of Primula obconica in all shades of colour. The plants were all in excellent condition, with a plentiful supply of bloom, and showed the results of careful cultivation. Pinks, pale and deep lilacs, light and dark blues and whites were all represented in flowers varying in size from ¾in. to 1¼ins. in diameter. The flowering stems carried the flowers well, and varied in height in the different varieties from 9ins. to 18ins. These hybrids are excellent subjects for providing a good display of colour in the greenhouse, and should find more favour in the future.

Messrs. Hillier staged an interesting collection of dwarf rhododendrons, collected by Forrest and Kingdon Ward in China and raised by Lord Headfort. Among them were the attractive pale pinks of R. racemosum and its relations, and F 20488 R. orthocladum, with tight heads of soft lilac-blue flowers. It is such dwarfs or semi-dwarfs as these that will prove so invaluable in our gardens when they become common enough to sell at a price cheap enough for all pockets.

An attractive display of hybrid freesias was staged by Mr. G. H. Dalrymple, the raiser of the much admired Freesia Wistaria. The colours, especially of the seedlings, were very varied: some were pinkish tinged with yellow and orange, others cerise, mauve or gold. The self colours in many cases were more effective than the shaded; the yellows particularly were extremely beautiful. All of them are excellent for decoration and easy to arrange artistically. Such varieties as Bluebeard and Mouette or Wistaria and Treasure form a pleasant contrast. Mr. Dalrymple was showing Goldfinch, a beautiful deep yellow with a golden throat; and Treasure, a pale yellow variety on thin wiry stems. Bluebeard is a bluish mauve freesia, and Mouette is pale pink in colour. Some of the varieties were very sweetly scented, others possessed only a faint trace of the true freesia fragrance.

Everyone loves the rose, whatever time of year it may be, and the exhibits of roses at Vincent Square this week had many admirers. Nearly every passer-by stopped to enjoy their fragrance and beauty, especially of those on the stand of Mr. Elisha Hicks. His roses were in excellent condition, vigorous and robust in growth. The colours also were good. The variety Mrs. Elisha Hicks proclaimed itself by its sweet scent, which was effective some distance away. From a point of view of colour and form this rose is somewhat over-rated. Paul's Scarlet Climber made a vivid patch of colour, while the beautiful variety Clovelly with its rich salmon shaded rose flowers, and such others as Betty Uprichard, Mme. E. Herriot, Lady Hillingdon and Madame Butterfly adorned the stand. Lady Hillingdon is of a shade which is hard to beat.

Messrs. Benjamin R. Cant and Sons were showing a splendid exhibit of Padre; the blooms were of good size and glowing in colour. This firm was also showing Sovereign, which is a good yellow bedding rose and is a variety which meets with great favour, as it is not liable to that dreaded disease, mildew. Phœbe, Autumn Tints and Diana were also exhibited. Messrs. Stuart Low and Co. were showing a charming sulphur yellow rose called Roselandia, raised by Mr. Walter Stevens. Most of the roses exhibited by Messrs. Allens were grown in pots and belonged to the Wichuraiana or the dwarf polyantha class. Some of these are ideal for forcing and are very decorative in a greenhouse, especially the varieties Messrs. Allens were showing. Of the dwarf polyantha type, Orange King is a dainty little specimen with a mass of tiny button-like flowers of quite a new shade of bright orange-salmon. La Reine Elizabeth, Ellen Poulsen and Mrs. William Cutbush were other examples. Lady Gay was undoubtedly the best Wichuraiana shown. The large pyramidal trusses of rosy pink flowers borne on long stems were very effective, which could not be said of White Dorothy. This particular specimen could hardly be called a pure white Wichuraiana, and is a poor thing at the best of times, with naught else but floriferousness to recommend it. Among the hybrid teas, Maud Cumming, Betty Uprichard, Lord Charlemont and Hadley were most noticeable.

As new narcissi are constantly being raised, seedlings good and indifferent are brought before the notice of the public, and one wonders which of them will become the proud possessors of a name and in time a place among the general collection of the average gardener. Some should be passed by, but others are an improvement on the existing varieties, while a few are decided breaks and have certain qualities lacking in the older kinds. The allotment of awards of merit is a strange business; it is difficult to understand why certain varieties are received favourably and others are considered unworthy of recognition. Some of the seedlings exhibited by both Messrs. Barr and Sons and Messrs. R. H. Bath and Sons were equal if not superior to those varieties which received awards of merit this week. Perhaps when these seedlings are put up for an award of merit the narcissus world will be taken by storm. The great variety in form and

(Left) PRIMULA MALACOIDES, GOLDEN EYE, OF FLORIFEROUS HABIT. *(Right)* PALE MAUVE FLOWERS OF PRIMULA × BARBARA BAKER.

Digitized by Google

colour, the vivid orange cups of the incomparabilis and Barrii seedlings, and the translucency of some of the flowers, called forth exclamations of surprise from many an onlooker. In some of the new seedling trumpet narcissi there is a tendency for the trumpet to be too large in proportion to the perianth, making the flower unbalanced; but no such criticism could be passed on a good variety like Golden Sunrise, which was exhibited by Messrs. R. H. Bath and Sons. The flowers are of great size, a uniform rich gold, and the open trumpet is elegantly frilled. This variety surpasses King Alfred, a similar trumpet daffodil. Bath's Flame was another attractive narcissus shown; it has a vivid orange cup and thin twisted segments. Some good varieties among the many others were Bernardino, Gaiety, Crystal Queen and Golden Dustman.

Wandering up and down before the stand of Messrs. Barr and Sons, one was astonished by the beauty and variety of the modern narcissus, and it was a bewildering task to select a few from among them. Superlatives could rightly be used to describe every one, and yet to be fully appreciated they should be seen. It is surprising that some people keep to the same old varieties when, as could be seen at the Hall this week, there are many others infinitely superior. Crœsus, a fine incomparabilis with a wide orange-red crown; Jasper, Nysa and Sunny Lass, typical of the Barri section, were exhibited by Messrs. Barr and Sons. Pax, St. Olaf, Orange Sceptre, Tamora and Lord Kitchener were various other excellent varieties.

Anemones seemed to occupy most space among the rock plants. A. blanda was present in all its forms, of which Scythinica, dead white within and steel blue without, is the most attractive. Maurice Prichard showed a good purple form of A. nemorosa and the eccentric variety of A. nemorosa bracteata, a Jack-in-the-green flower with a green ruff and a double row of tousled white petals. Messrs. Reuthe showed A. vernalis, a flower of the melting snow, with a deep cup of ivory white enclosing a mass of soft yellow stamens, the outer surface of the petals washed with greyish blue and covered with silky hairs. A. ranunculoides, whose bright buttercup yellow is a break from the family tradition, was shown by Mr. Frederick Wood of Ashtead, who also exhibited a group of Fritillaria pyrenaica, a flower that has the sinister attraction of deliberate ugliness. The heavy waxen bells, greenish yellow inside and dingy purple, heavily bloomed, without, are set off by the pale glaucous foliage and exhale a faint corpse-like odour. They made an excellent foil to the innocent forget-me-not blue of Mertensia virginiaca. Clarence Elliott and Co. gained an award of merit for the hybrid Primula pubescens Barbara Barker of their own raising (Zuleika × Linda Pope), a large pale mauve flower with regular, overlapping petals and a white eye; and another award for Rhodothamnus chamæcistus, which is very nearly a rhododendron, but tolerates lime, and is, therefore, a very valuable little shrub, for it produces its flat, pale pink *Alpenrosen* very freely and is still a decorative little bush when out of flower. Messrs. Waterer showed some vigorous plants of Epigæa repens, that powerfully fragrant little shrub that makes wide mats in shady woods of North America, but seldom, unfortunately, shows the same activity in this country. Another very attractive North American plant, Calypso borealis, a fantastic little spider orchid with twirled wings of purplish pink and labellum blotched like an odontoglossum, was shown by Messrs. Reuthe.

Other exhibitors were:

Carnations.—Messrs. Allwood Brothers and C. Engelmann.

Cinerarias.—Messrs. Sutton and Sons.

Forced Shrubs.—Messrs. L. R. Russell and Stuart Low and Co.

Fruit.—Messrs. Bunyard and Co.

Orchids.—Messrs. J. and A. McBean, Charlesworth and Co., R. Gerrish, H. T. Pitt, and Sanders and Co.

Polyanthus.—Messrs. John and A. H. Crook, K. and E. Hopkins, G. A. Miller and Mrs. Barnard.

Rhododendrons.—Messrs. Hiller and Sons and G. Reuthe.

Shrubs and Alpines. — Messrs. Bakers; J. Cheal and Son, Limited; William Cutbush; Maxwell and Beale; Carter Page; W. H. Rogers and Son, Limited; and Skelton and Kirby.

St. Brigid Anemones.—Messrs. Reamsbottom and Co.

Topiary.—Mr. John Klinkert.

Tulips.—Messrs. Carter and Co.

Violets.—Mr. Baldwin Pinney.

NEW AND RARE PLANTS.

PRIMULA × BARBARA BARKER. — A dainty little hybrid forming a neat, almost a rosette, cushion. For its size it appears very floriferous, carrying ten to twelve flowers. In colour the flowers are pale lilac mauve with a white eye. The flower is very shapely and compact, with the petals close-fitting and overlapping. They vary from ½in. to ¾in. across. This variety should prove of great value either in the rock garden or as a pot plant. Award of merit. Shown by Mr. Clarence Elliott, Stevenage.

RHODOTHAMNUS CHAMÆCISTUS.—One of the most beautiful natives of the eastern and southern Alps, clothing the limestone screes with tussocks of dense tiny shoots covered with their small fringed and hairy leaves of bright green. The plant exhibited showed these characteristics very well indeed, and in addition carried the delicate saucer-shaped flowers of a pure pink colour. Each is carried on a single delicate stem. It is one of the most beautiful inmates of the rock garden, forming cushions of great charm. Award of merit. Shown by Mr. Clarence Elliott.

PRIMULA MALACOIDES GOLDEN EYE—An excellent hybrid of the type species, with a dainty, almost feathery, appearance. It is of compact habit and very floriferous, bearing clusters of white flowers with a pretty golden yellow eye. The petals are rather prettily cut. The flowering stems vary in height from 6ins. to 9ins., and can scarcely be seen when clothed in their mass of flowers, which contrast well with the light green of the foliage. Award of merit. Shown by Messrs. J. Carter and Co., Raynes Park.

CARNATION SHOT SILK.—Blooms of a perfect shape and colour of a twin shade of light and dull red which makes an excellent blend, fully justifying the varietal name. The calyx is firm and shows no sign of bursting in the expanded flower. The petals are regular and prettily crisped. The flowers, which are large—2–3ins. across—are carried well on the rather drooping stems. Award of merit. Shown by Messrs. Allwood Brothers. Haywards Heath.

LACHENALIA GLAUCINA.—A rather dainty species carrying many small pale green to yellowish flowers on each flowering stem, which varies from 6ins. to 9ins. in height. The bells are carried more or less rigidly on the stem, pointing outwards and upright. Award of merit. Shown by the Rev. Joseph Jacob, Whitewell Rectory, Salop.

NARCISSUS PILGRIMAGE.—A fine yellow incomparabilis variety bearing perfect flowers of a pure soft delicate yellow colour. The trumpet is prettily crisped at its outer edges. The blooms are carried well on the long erect stems. Award of merit. Shown by Herbert Chapman, Limited.

NARCISSUS IRENE COPELAND.—This variety carries double flowers of a pale whitish yellow colour, almost transparent. Some of the petals are pale yellow, while others are white. The pale yellow petals are said to become white when exposed to sunshine. It is not a variety which impresses one with its great beauty, the reason probably being the fact that it possesses a double flower, which nowadays is not looked on so favourably as single-flowered varieties. The blooms are well presented on long erect stems. Award of merit. Shown by W. F. Copeland, West Shirley. Southampton.

ORCHIDS.

ODONTOGLOSSUM CLODAGH (Lakinæ Nathaniel).—A showy hybrid with an erect spike of six flowers, all the segments heavily blotched with chocolate-red, the broad labellum displaying more of the white ground than the other segments. From Mr. R. Gerrish, Milford Manor, Salisbury (gardener, Mr. Sorrell). Award of merit.

ODONTOGLOSSUM CORDOBA (eximium × Doris).—One of the best varieties of this hybrid, which was first recorded by Dr. Lacroze in 1918. The spike bore eleven flowers, compactly arranged, of almost solid reddish blotching, the labellum having a broad white margin. From Mr. R. Gerrish, Milford Manor, Salisbury. Award of merit.

CYMBIDIUM VESTA VAR. THELMA (Alexanderi × insigne).—The arching spike of this hybrid carried nine large flowers, all the segments broadly developed, and of a blush-pink tint, the labellum lined and dotted with crimson, the column deep rose colour. From Messrs. J. and A. McBean, Cooksbridge, Sussex. Award of merit.

Gold medals were awarded to Messrs. J. and A. McBean, Cooksbridge, Sussex, for an extensive group of various species and hybrids; and to Mr. R. Gerrish, Milford Manor, Salisbury, for a well arranged exhibit of choice species and hybrids, the excellent cultivation of which was rewarded by a silver Lindley medal being given to the gardener, Mr. W. Sorrell.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

CORRESPONDENCE

MALUS THEIFERA.

SIR,—On page 61 of THE GARDEN issued January 31st appears an interesting account of Malus theifera from the pen of my friend, Charles Leray, telling of the behaviour of this new crab apple in Europe. From the illustration accompanying the article one gets the impression that flowers and foliage are expanded at the same time. If this is its normal behaviour in Europe, then I fear the plant is less ornamental than in a wild condition in China. The accompanying photograph shows how this fine crab apple flourishes in the Arnold Arboretum, yet the picture might well have been taken of the tree on its native heath, so closely does it simulate the habit and character of the plant in a wild state. Some of the branches are from 12ft. to 15ft. long, and from tip to base are thickly strung with blossoms. It fruits in equal profusion. The combined effort, however, has an exhausting effect, and the tree is at its best in alternate years. Unlike many crab apples, M. theifera comes true from seed.—E. H. WILSON.

MALUS THEIFERA IN THE ARNOLD ARBORETUM

ALUM FOR SLUGS.

SIR,—May I please say a few words regarding the alum treatment for killing slugs? Since Mr. Richardson first wrote with reference to the use of alum, I have tried it in several ways, and have found it very useful indeed. I think the following method is the best. Crush the alum to as fine a powder as possible. (If it can be obtained in a really fine powdered condition, further crushing will not be necessary, but the "powdered" alum I have been able to purchase has generally been in a rather lumpy condition), and sprinkle it over the border after dark when the slugs are on the move, choosing a mild night for the purpose. In order to sprinkle the powder evenly, a tin should be used, having the lid perforated with small holes not more than 3-32in. in diameter. When sprinkling the powder some sort of light will be found useful in order that it may be seen how the powder is being spread. A thin sprinkling is all that is necessary, and the number of dead slugs which will be found on a visit to the border in daylight will furnish the necessary evidence of the efficacy of the treatment.—H. R. C., *Wimbledon*.

IRIS TINGITANA.

SIR,—In your issue of February 21st, "B. K. G." asks for the experiences of your readers in flowering Iris Tingitana. So far I have had no difficulty with it. Last autumn as an experiment I sent for six bulbs from Messrs. Barr, and planted them the first week in October. They are planted in the open, in sand and leaf-mould, but sheltered from the north and west by walls and getting a fair share of southerly sunshine. All six bulbs threw up flowering spikes in due course, and the first flower was fully expanded on January 22nd. Since then the rest have followed suit, each stem bearing two lovely azure and gold blossoms. But, from what I am told, unless we get a much warmer summer in 1925 than we had in 1924, the probabilities are that next year the percentage of flowers will be much smaller. Also, I must admit that up to the present we have not had any frost or really cold weather.—E. F. C., *Guernsey*.

IRIS RETICULATA.

SIR,—I have read with great interest Mr. Dykes' delightful article on "Some Garden Iris," but am much surprised at his omission of the lovely Iris reticulata from his collection. It is somewhat fanciful as to the soil it prefers, but, given a light stony soil, it flourishes and increases in an extraordinary way, throwing up its fragrant royal purple and gold blossoms in February regardless of weather. It should be lifted every alternate year in late June, when the foliage has died off yellow, and replanted in August in well dug soil. Many people think it is too dainty in its tastes to appreciate fertilisers, but,

Digitized by Google

short of planting in raw farmyard manure, nothing comes amiss to it. Soot, lime, mortar rubbish, superphosphate, fish manure, well rotted stable manure, it eats them all with the greatest avidity and the best results. Care must be taken, however, to give nourishment little and often. The blossoms open in water when gathered in bud, and last over a week in good condition. On the whole it is the showiest and at the same time the most uncommon flower to be seen in the garden at this early season, and, where it thrives, of the easiest cultivation. It is astonishing it is so little grown.—AN IRIS LOVER.

DIGGING AND TRENCHING.

SIR,—The writings of Mr. E. Beckett on anything pertaining to the cultivation of vegetables and the treatment of the soil are read with avidity by thousands of gardeners and allotment-holders. He is also often quoted at meetings of the above. The question at issue on digging and trenching, especially that relating to the bringing of the subsoil to the surface, is frequently debated, and from my own experience there are numbers of cultivators who hold the opinions of "J. H."

Personally, I always advocate great care in trenching, and for safety's sake to keep the subsoil in its place until it gradually becomes in good condition, and then as gradually bring it to the surface. The reason for this is that instances have occurred where the subsoil, having been brought to the surface, nothing would grow in it, at least for a season or two. It is here that I feel it would be good if Mr. Beckett would shed further light on the subject. For instance, what treatment would he give the top spit before cropping, the first season after trenching?

One would also be much interested to learn Mr. Beckett's experience during the first season or two after he commenced his method.

I should only advocate the bringing to the top of the lower spit when plenty of material is assured for working into it, more especially if the soil is of a stiff nature; in this case, if ample supplies of stable manure, lime rubble, road grit, burnt refuse from the rubbish heap, leaf-mould and so on are available, and the work can be carried out in late summer or early autumn, and the trenches left ridged, the soil will then be in good condition for cropping during the following spring, especially if it receives plenty of working previously.—G. H. H.

SIR,—I have just read Mr. Beckett's letter in reply to mine *re double* digging or trenching of heavy clay soils. I draw attention to *double* digging, as I did not in fact mention digging simply.

I trust Mr. Beckett does not think for a moment that I, or anyone else for that matter, doubt his statements as to the results he has obtained by his method of treating heavy land, but what suits one class of soil and locality may and does often fail in another.

My experience extends over nearly as many years as Mr. Beckett's, and it has been my fortune, good or bad, to be mostly on clay, and I have proved by experience that it is a mistake to bring sour, poor subsoil to the surface and expect to grow good crops on it, the first year at any rate.

In the West of Scotland during the past two years, gardeners have had to be content with the *good* ameliorating influence of rain alone, which, as anyone knows, does not do much in the way of breaking up clay even when exposed on the surface.

If one could depend on a week's good hard frost, things might be different, or even a reasonable spell of dry weather; but unless there is unlimited supply of labour, and good opening material to apply to the surface, I find it best to leave the subsoil below; but by all means break it up every year, if possible.

One can hardly accept the fine specimens of vegetables shown by Mr. Beckett as ordinarily grown garden crops. At least ten times the labour must be spent on primary preparation and subsequent attention that any ordinary gardener can find time for: hence my only reason for writing.

Should opportunity offer, I will be most happy to avail myself of the kind invitation to Aldenham, not that I doubt in the least the excellence of the results or the nature of the soil, but for the pleasure of making the acquaintance of such a noted grower of vegetables.

But I still warn anyone to be careful in going too far in bringing barren soil to the surface in the hopes that nature alone may work a miracle and turn it into something better.—J. H.

PLANTING THE WATER GARDEN.

SIR,—May I correct an error that occurs in my article on page 158 of the issue of March 21st, due, I am afraid, to faulty punctuation in the typing of the MS. The words, "The best of them is a wonderful and richly coloured violet. This is one of the species that only gives of its best under moist conditions of the soil," refers to Iris Delavayi and not to I. Wilsoni.

True, Iris Wilsoni also does best in moist soil, but it is yellow, not violet, and, except that the conditions of cultivation are the same and that they are said to cross freely, the two have little in common. Delavayi grows twice the height of Wilsoni and is by far the better plant of the two.—GEO. DILLISTONE.

BLACK CURRANTS.

SIR,—I have been much interested in the notes from your contributor, Mr. G. F. Copley, in the issue of THE GARDEN for March 7th on the subject of black currants I am surprised that he does not mention that super-excellent variety—when it is obtained true to name—the Baldwin. Boskoop will beat it for weight of crop about one year in eight, at all other times the Baldwin is, in my opinion, far and away the best variety in cultivation. The berry is large, the clusters long and it fruits right up to the wood. It is of very strong flavour and therefore valuable for preserving, particularly to the professional jam-maker, and its strong skin enables it to travel long distances and arrive in good condition. Many tons have gone from this neighbourhood (Herefordshire) to Scotland.

One of the secrets of growing this variety to perfection is to give the bushes a little protection during the blooming period. It is almost the first sort to blossom, and the biting winds that are so often prevalent in March have, I think, more to do with a failure than is generally realised by gardeners. This precaution is, of course, impossible on a commercial scale, though simple in a garden, but even so we have scrapped all other sorts here in favour of Baldwin. There is another point that is not generally made enough of by gardeners, and that is the value of strain. Just as in the breeding of live-stock, so in the planting of black currants, and particularly of Baldwins, strain is important, and I would urge upon all intending growers this advice: "Be careful where you get your stock and that it is sound and well grown. Get a guarantee of truth to name, and you will not regret your pains." An example of the value of strain and the way it is appreciated by the professional fruit-grower as distinct from the garden grower is shown by the fact that we have sold close on a quarter of a million Baldwin bushes of our own strain in the last three or four years, and have sent them to districts varying from the north of Scotland to the south of England and from Wales to Norfolk at prices very nearly three times those at which at least three of the varieties quoted by your correspondent were freely offered. —A. H., *Ledbury*.

CONCERNING CYCLAMENS.

SIR,—Is it not rather remarkable that firms specialising in cyclamens do not pay more attention to the scented strain of this plant? That such a strain exists—but is not general—was amply proved by THE GARDEN in an article three or four years ago when it described a noted scented collection of a private owner. I believe Messrs. Barr offered, later, seed from this source, but in their catalogue for this year no such mention is still made. Messrs. Barr, however, make the statement in their seed catalogue that the cyclamen is a fragrant greenhouse bulb. This is a much too generous eulogy, for, speaking generally there is no more sweet smell attaching to a cyclamen flower than there is to the corm from which it springs. So far as my experience and observations have gone, a fragrant cyclamen plant is a rarity. You may go several years and not get one scented plant from a sowing of seedlings or a purchased collection of young plants. On the other hand, one may get a pleasant surprise from any given sowing. I had such three years ago, and the fragrance still persists in the latest progeny. There is no mistaking this sweet attribute, and anyone can easily detect the plant so possessed among a batch of other cyclamen in flower. Not long ago two plants were put in the drawing-room of the manse here—one a scented seedling specimen, the other an ordinary or non-scented plant. The former was soon picked out and commented on, proving that the quality claimed was quite distinct and noticeable. May I mention another instance? Some time ago, looking round a good class garden, I was shown a most sweet-smelling white cyclamen plant, the only such example out of half an ordinary span-roofed house collection. The then head-gardener said he had never possessed the like before. The colour of the flower here is a soft rosy pink. I know of no firm even mentioning fragrance in connection with cyclamen other than the above reference given. Can it be the acquisition of sweetness in this flower is not considered to be, by the experts, a step forward in the all-round perfecting of this plant? If not, why not?—C. TURNER, *Ampthill Park*.

NATIVE PLANTS.

SIR,—You have, Mr. Editor, done well to draw attention to the collection of native plants. I quite agree that many native plants are difficult to establish in gardens. I never try to transplant wild plants found growing on our hills and in the dells, because, from experience, they proved to be very stubborn to establish, in fact, nine times out of ten they absolutely refused to grow. The method which I have found most successful, and give for what it is worth, is to leave the parent plants growing, and, instead, take off a few cuttings. Cuttings seldom fail if treated properly in a cold frame. Strip off a few shoots, tie a little damp moss round them, in this way the shoots will remain fresh until time will permit to place them in a frame. A few years ago I came across a lovely batch of white heather, in full bloom, on one of the hills in Banffshire. Afraid to lift a plant I stripped off two dozen young shoots, took them home and placed them in a cold frame among peat and sand, where they took root and formed lovely plants. From these plants many sprays of white heather have been sent to friends abroad.—GEO. STUART, *Edinburgh*.

SIMPLE GARDENING

PLANTING GLADIOLI IN APRIL.

THE corms may be planted from early in March to the middle or end of April to secure a long season of resultant flowers. In heavy soils early planting is not advisable, as the corms do not begin nor continue to grow well in such ground. To overcome the difficulty the corms are planted in pots and the growing plants are duly planted out in prepared ground. In nearly all kinds of soil the corms may be planted in April, and it is from these corms that the best spikes are available for shows held during August. Some varieties are earlier-flowering than others, and, of course, these should be planted last. If we take the middle of August as a date when, approximately, the flowers are required for exhibition, such varieties as Pink Perfection, Princeps, Flora, War, should be planted first. A few days later plant Baron Hulot, Empress of India, l'Immaculée, Maréchal Foch, Red Emperor, Yellow Hammer and White Giant. Ten days after the first planting, plant Golden West, Halley, Prince of Wales, America and Panama. The earliest or main spikes will be available first, and from a few dozen corms spikes may be cut till as late as early September.

Gladioli are not really difficult to grow, but they respond to good treatment, producing extra fine spikes and individual flowers. The corms should be planted 3–4ins. deep, each one surrounded by a little coarse sand, and 1ft. apart. Manures used should not touch the corms. Surface mulches are beneficial in hot weather.

PRIMULAS FOR THE GREENHOUSE.

There are many very beautiful families of primulas suitable for furnishing the greenhouse and conservatory, such as kewensis, fine for mid-winter blooming; obconica grandiflora, also for mid-winter, malacoides, for late winter and spring; but I am now referring mainly to the raising of plants of Primula sinensis, as these require rather more care and skill to grow really well. There should be two sowings, one now and a second about the third week in May, not later than the first in June. I recommend pots or pans in which to sow seeds, rather than boxes. Good loam and leaf-soil in equal proportions with a free sprinkling of old mortar rubble makes a suitable compost. Fine sand should not be used, only very coarse, dry sand. Drainage must be efficient, as any stagnant moisture would be harmful to the seedlings. The soil in the pan should be watered one hour before the seeds are sown, cover the seeds with a very thin layer of soil, then place a sheet of glass and some brown paper on to exclude light. As the seeds take a long time to germinate, some much longer than others, very thin sowing is advisable so that the more forward seedlings may be lifted and transplanted without disturbing seedlings just breaking through the soil. The first transplantings should be done round the sides of large pots, not in the centre. The next shift should be single plants in small pots and frame treatment.

VIOLETS; LAYERING AND PLANTING.

There is no better time for layering violets than during the month of April. Old plants growing in frames should be dealt with early in the month and those in outside borders towards the end of it. Of course, suitable runners cannot be grown in one week, they must be selected and taken care of previously. But at this season, on most plants, they are usually plenty to meet the demand. It is not necessary to use any special soil for layering, that on the surface of the bed will do nicely. In the sketch *a* shows a portion of an old plant, *b* the young one nearest to it on the runner, and *c* the end of the runner which would

bear another young, but weakly plant; the stem is cut off at *e* and at *d* a small stone is placed on the surface soil and stem to keep the latter firm till roots are formed. The young rooted plant *f* is shown with both ends of stems *e*, *e* severed. In the meantime the summer quarters should be prepared so that the young plants can be taken to the beds and planted forthwith. Violets thrive best in a cool border and in a position where they will not be subject to cold draughts as the latter soon encourage the spread of red spider. Avoid over dryness. Plants of the double varieties may be divided if there is a lack of runners.

TOMATOES TO FRUIT OUTSIDE.

Although the weather, in some years, is adverse to successful cultivation, nine out of ten amateurs like to try to grow tomatoes well outside every year. During the abnormally hot summer of 1921 tomatoes grew in rows in the open quarters like potatoes and ripened fruits quite early. The plants thrive in heat and a comparatively dry atmosphere. Ordinarily, it is too risky to expose them in open beds. Sheltered positions, such as borders near to walls and fences facing south, south-west and south-east are the ideal ones. Cultivators who do not possess such quarters may make a good substitute by having a row of runner beans north-west to south-east and planting tomatoes about 4ft. away on the side facing south-west. The runner beans form a good sheltering background, and on account of their dark foliage it is generally very warm immediately in front of them. But it is very essential to success that strong advanced plants be available to plant out about June 5th in the south and June 12th farther north. Strong pot plants, judiciously hardened, are suitable, of course. Where it is not convenient to have pot plants, make up a bed in a temporary shelter as follows: First put down a layer of ashes 1in. thick, then a layer of rotten manure 2ins. deep, and finally a nice, rather lumpy compost 4ins. deep. Plant at a distance of 7ins. apart each way. Cover and attend to the plants. When finally planted, each specimen can be lifted with all soil, down to the ashes, adhering, and a check will not occur.

VEGETABLE MARROWS AND FRAME CUCUMBERS.

If small frames are available for placing on the beds containing the young plants, the latter may be planted in their permanent quarters early in May; but as such frames are not always available, the plants must be potted or transferred to boxes and kept in the cold greenhouse or frame till the beginning of June. After the plants have filled their small pots with roots they should be potted on, as otherwise the leaves would soon turn to a sickly yellow and thus lose strength and valuable time. The middle of April is a suitable time for sowing the seeds. Use a mixture of old chrysanthemum soil and leaf-mould; place one seed in a 3in. pot and, if necessary, repot into a 6in. one rather than starve a healthy seedling. In the meantime, prepare the summer bed for the plants, not a heap of litter with a thin layer of soil on the top, but a flat-topped bed about 1ft. high and composed of rotted manure, decayed refuse from the garden heap and ordinary soil. In such a medium the plants will thrive and hold out in hot weather. Frame cucumbers may be grown without a hot-bed; but the fruits, if a long time swelling, are frequently bitter. Litter and tree leaves, or even the latter alone, form a nice hot-bed on which to place a frame. At first, light friable soil to a depth of 9ins. should be placed all over the bed, and due top-dressings applied later. Till the middle of June mats should be laid on the glass every night.

GEORGE GARNER.

THE SIGNIFICANCE OF LEAD ARSENATE SPRAY

ITS UTILITY AND ITS DANGER.

"WHEN the petals are falling, spray with lead arsenate sprays," says many a treatise on the destruction of fruit pests. That is advice which, judiciously followed, will put a prompt end to the career of armies of tiny grubs which, left to themselves, will find a snug retreat in the cores of fruits with ultimate results which are too familiar to require description.

It should be unnecessary to warn owners of fruit trees that the open winter has once more given an easy hibernating period to the pests which plague the gardener and play havoc with the occupants of the orchard and their crops. Some have sprayed once with some sort of winter wash, some have made a second effort with lime sulphur, others have not sprayed at all, and it is to these latter that a message of urgency is specially directed, for here is another opportunity, and, so far as certain very troublesome grubs are concerned, it is the final chance of the season for an effective onslaught.

The codling moth is a very prevalent pest throughout the orchards and gardens of the British Isles, and it is something of a reproach that this destructive pest has not yet appreciably diminished in numbers and virulence, for it is far from being the most difficult of pests to deal with. Several means of destruction are at the service of cultivators which may be termed alternative measures, but would more properly be brought into co-operative action as will here be explained.

There can be no doubt that an acquaintance with the character and life-history of a pest greatly assists in ensuring success in efforts to combat and annihilate it; therefore our first step shall be to study the codling moth and its larva or grub.

Carpocapsa pomonella is the scientific name for the moth, which is of moderately small size, the expanded wings measuring about three-quarters of an inch across, while the body is just about half that length. The antennæ or horns are one-sixth of an inch, spreading almost horizontally with sharply incurving points.

The dominating tint of the forewings is an earthy grey, with dark blotch at the shoulders, and faint transverse, waved stripes of light grey and creamy white variegating the outer half of the wing. The underwings are a dull gold or russety orange, the extreme edge being regularly scored with parallel white marks of hair-like fineness. The grub is of a dirty ivory tint encircled by deeply impressed rings, the head being dark glossy brown.

About the latter end of May the moth is in flight, and is very industrious, flitting from cluster to cluster of the newly set fruit, depositing one egg on each fruit. The apple is a favourite host, but pears are also subject to attack.

It takes but a few days for the eggs to hatch, and the diminutive grub immediately gnaws a tiny tunnel to the interior of the fruit, there to fatten itself upon the softest pulp around the core-walls. Within a month the grub is fully grown, when it travels to the surface of the apple or pear, spins a silken thread by means of which it drops to the ground. The next manœuvre is to seek a cosy crevice in some abrasion of the bark of the tree trunk, or under a covering of lichen or algæ, and there pupate until the following May, when the perfect moth appears to commence a fresh cycle of life.

The opportunity for catching the pupæ unawares with caustic washes is past, hence the importance of waylaying the larvæ immediately they are hatched, and before they can gain access to the interior of the tiny fruits. This is the object of spraying with lead arsenate wash, the importance of promptitude surely being perfectly obvious. No spraying can be done while the trees are in full bloom, but as soon as petals have fallen the spray should be upon the trees. The date of arrival of the moth is not to be definitely foretold, but as lead arsenate is a virulent poison which will retain its power for a long period, it is prudent to ensure being in good time.

Lead arsenate is produced by combining acetate of lead with arsenate of soda, but as these are deadly poisons, and capable under careless handling of grave mischief, no recommendation will be made that the spraying compound should be manufactured at home, nor is there the slightest necessity that it should be attempted, for there are abundant proprietary brands of lead arsenate paste on the market made by such highly reputable firms as Lewis Berger, Voss, Strawson, Murphy and others which simply require the addition of water to make them ready for use.

One does not idly recommend the use of virulent poisons, but the scourge of destructive fruit pests is so serious that no available means of real destruction can be ignored, and the vital necessity is that all owners of fruit trees should do their duty in the interests of neighbouring growers as well as themselves, for it is only by concerted effort that the plague of the codling moth may effectively be trampled underfoot. It is equally necessary that the operator shall be alive to the danger attaching to careless handling of poisonous sprays.

It is no task for the garden boy, and adults should realise that no food crops, such as lettuce, cauliflower or other greenstuff, should be allowed to receive the slightest particle of the solution, therefore spraying must be done only on windless days. Wear gloves and otherwise take rational precaution against bringing lead arsenate or other such poisons into contact with persons or foods.

The codling moth is by no means the only pest for which this powerful spray is a deadly weapon. The currant moth, the gooseberry sawfly, larvæ of winter moths which were not caught by grease-banding succumb to lead arsenate, but although its power is such that it would be a wonderful weapon for use throughout summer, its virulence prompts the counsel that its use should not be extended to the period when varied crops are maturing for use. With caution there is safety; those who cannot exercise care even with poisons should never be allowed to deal with food crops.

Mention of grease-banding recalls the fact that many larvæ of the codling moth have been caught by their aid. It frequently happens that the mischief caused by the grubs inside growing apples causes the latter to fall prematurely. The grubs in the fallen fruit soon work their way out and commence to re-climb the tree trunks. A freshly smeared greaseband around the tree trunk, not too high, will arrest the progress of the grubs and capture them. From late May to July covers the period during which greasebands for this purpose should be kept frequently freshened by re-smearing with grease.

THE SOURCE OF PLANTS

AT this time of year I should give a dissertation on the joys of spring; if I could, I should write a thrilling and, perhaps, grilling account of a garden at Timbuctoo. And yet, pleasant though heat may be, it is not really good for gardening. Gardens in the tropics on a whole are poor things. In Java, for instance, the only flowers that I can vividly remember as inhabitants of gardens are cannas, gardenias and various members of the large family of convolvulaceæ. They are bold and flashy in flower, like some overdressed dowager, but they are unsatisfactory from the æsthetic point of view; there is nothing personal or affectionate about them. They are all too fat or too luscious; they either smell too much or not at all. I remember arriving at a hotel in Java, I think it was at Djokjokarta, and choosing a bedroom because outside the window there was an enormous bush of gardenia in full flower. It must have been 10ft. high and 8ft. through, and every morsel of it smothered in bloom. This thrilled me and I imagined the night air made fragrant by the smell of these hundreds of blossoms being wafted into my room. So heavy and sickly was the air that I woke up in the night with a headache, knocked over the candle in looking for the matches, trod on a cockroach while looking for the candle, disturbed a praying mantis at his devotions on the verandah, and so shattered any romance that I had regarding the gardenia. I now look upon it as a buttonhole flower, and look upon masses of it from a distance.

A friend of mine once told me of his first sight of a big rafflesia—I think it was in Sumatra—an enormous purple cup, like a gigantic crocus, rising from the decaying trunk of a tree. It looked weird and rather beautiful at a distance until on examination he found that the petals were so fleshy and smelled so much like carrion that they were riddled with fat, squashy-looking maggots. And so is romance in tropical flowers usually destroyed. They are gross and rather bestial.

The same thing happens when temperate flowers are grown in the tropics. Those that have any individuality worth talking about refuse to grow; others lose their delicacy and fragrance and become overfed and coarse. There is little doubt that the fight for life against odds makes for individuality and elegance and good breeding. Whenever a plant finds life too easy it becomes rank and gross. We hear of all that is best in China—the rhododendrons, primulas, meconopsis—but we never hear of the ragtail and bobtail's of the Chinese flora, of the masses of coarse rubus and heracleums and senecios and saussureas and impatiens which tousle many a fine landscape with their coarse growth. In the tropics all plant life is easy, if the plant will grow at all, which makes for uninteresting flora and horticulture.

With all our difficulties in the way of climate, gardening at least is fascinating in this country. The element of doubt and the gamble on an unknown horse satisfies our adventurous spirits, but, if only the origins of plants are traced to their sources, look what a wonderful world tour lies before us: Berberis Darwinii and fibrous-rooted begonias from the Andes, mimosas and gums from Australia, Plagianthus Lyalli from New Zealand, gladioli from South Africa, cherries from Japan, primulas from China, rhododendrons from the Himalayas, orchids from the Amazon, peaches from Georgia, heaths from the Mediterranean, gentians from Switzerland, azaleas from the United States. Their variety is unending and the interest is immense. And yet how few gardeners realise the fascination of tracing plants. Their desire begins and ends in the knowledge that a plant came from a reliable source, that it is the right colour, and that it is easy to grow. There is a great deal of romance hidden in the introduction of plants, and in addition, as I have pointed out before, there is the added advantage of finding out something about a plant's mode of life. There is sure to be some book of travel in the library which will describe the climate and appearance of a country even if the collectors omit to do so. For instance, I should advise all who are interested in plants from Yunnan and Szechuan to read "Three Years in Western China," by Sir Alexander Hosie. He only mentions economic plants, but gives a description of the country which is eminently practical and readable, and which will be found exceedingly useful to anyone who intends to visit that part of the world. Similarly, we have numerous volumes dealing with other countries from a geographical standpoint which are both interesting and full of instruction.

DWARF SHRUBS IN THE ROCK GARDEN—I

BY DR. R. LLOYD PRAEGER.

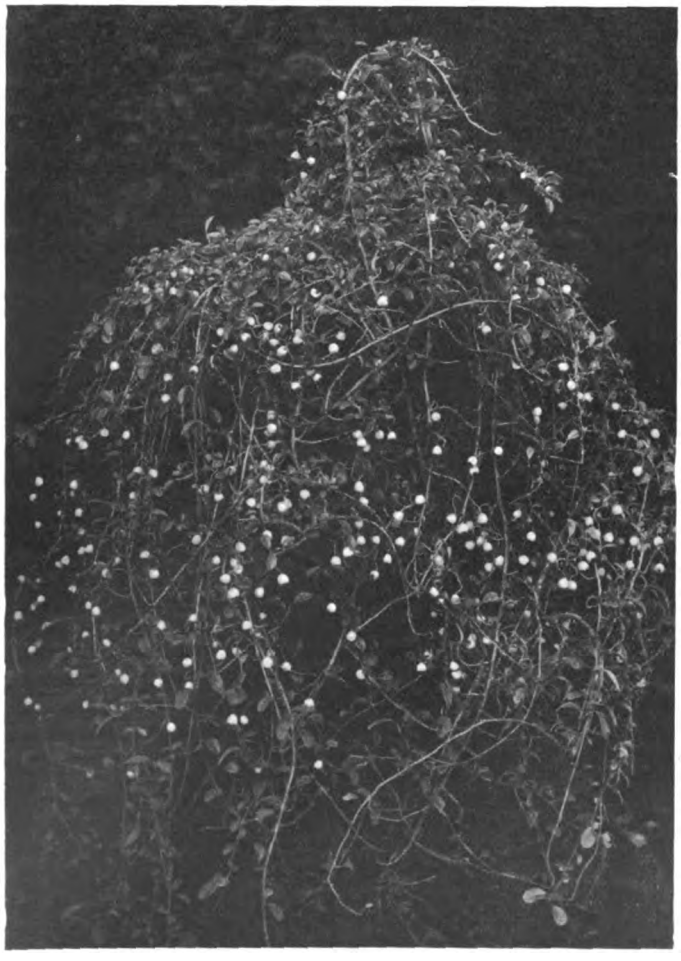
DWARF SHRUBS OF ALL KINDS SHOULD FIND A PLACE IN THE ROCK GARDEN, NOT ONLY BECAUSE OF THEIR EFFECTIVENESS IN WINTER BUT ALSO FOR THE CONTRAST THEY AFFORD TO MANY FLOWERING SUBJECTS ALREADY THERE.

THE use of dwarf shrubs among the boulders and slabs of stone and the cushions and carpets of greenery that together form the essential features of the rock garden is general, and, when properly directed, advantageous. It is only in a small degree logical, as very few of the shrubs which we employ for the purpose are natural inhabitants of either alpine heights or rocky places. But in the rock garden we usually strive to break up into ridges and hollows and sheltered nooks what might otherwise look merely like a slope artificially strewn with stones. This is, of course, most fitly done by the rocks themselves, but very few of us can emulate Edinburgh and import two-ton blocks to produce an effect of pinnacle and recess; and here the dwarf shrub is of great assistance.

Then again, shrubs are much more useful than rocks to give shelter—just as a hedge breaks the wind while a wall only produces eddies. And a rock garden is, in spite of all our efforts, in reality such an artificial thing that the presence of alien shrubs does not make it more so. Thus we may justify the use of the shrub which forms a mound or pyramid of foliage. There is another important group of shrubs which are prostrate, spreading over the ground or falling in cataracts over rock-faces. These really take a place among the rock plants themselves; their growth and their use are similar to those of many pinks and thymes, arabis, aubrietia and so on. And perhaps we might make a third category to include the really tiny shrubs, like cassiope, bryanthus and the smallest of the willows and veronicas, which also we use as we would an alpine plant.

Taking together the dwarf trees, shrubs and sub-shrubs which, under various circumstances, it may be advantageous to use in the rock garden, we have quite a considerable army, allowing us a wide range of choice—tall, or short, upright or creeping, dense or slender, evergreen or deciduous, with leaves and flowers of every shape and colour. It is impossible to arrange them in any natural sequence, and for convenience we shall use the rough growth-form classification already sketched. We may begin with the smallest examples, as these for practical purposes come nearest to the rock plants themselves.

A DWARF SPECIES FOR THE ROCKERY, RHODODENDRON INTRICATUM WITH LAVENDER BLUE FLOWERS.



ONE OF THE MOST DISTINCT TRAILING SHRUBS OF RECENT INTRODUCTION, COTONEASTER HUMIFUSA.

Cassiope is a genus of about a dozen tiny heath-like plants, a few inches high, with minute, often adpressed leaves and single white or pink bells like lily of the valley. They are mostly difficult, for they come from high alpine or arctic places and need a cool damp soil and climate. C. tetragona is much the easiest, and often does well in a shady, peaty, well drained spot.

Phyllodoce (or bryanthus) also belongs to the ericaceæ, and is a small group of delightful tiny shrubs with clusters of white or pink hanging bells. P. empetriformis is the most satisfactory in the garden, with little yew-like leaves and abundance of rosy bloom. Like the last, it must have a lime-free, moist soil, and is fond of peat.

Loiseleuria procumbens, the "mountain azalea," is the tiniest of all: a minute creeping shrublet not uncommon in the Scottish Highlands, and widely spread over alpine and Arctic Europe. Its dark evergreen leaves and erect rosy bells are very pleasing. The species of the three genera so far named, all need the same treatment, and all are difficult in southern England; in the north of Scotland probably all would do much better.

The gaultherias are also ericaceæ, and also like peat and shade. They are pretty evergreen low shrubs with bell-shaped blossoms not very conspicuous. G. trichophylla and G. nummularioides are quite small, only a few inches high, spreading by underground shoots; G. Veitchiana is pleasing, and larger in size; G. Shallon is rather rampant for the rock garden, and suits the woodland better.

Digitized by Google

Even yet the list of small ericaceous gems is not exhausted. There is Bruckenthalia, a delightful evergreen shrublet with heath-like leaves and rosy bells, quite easy in a light peaty soil; Vaccinium Vitis-idæa, the native cowberry, makes a healthy evergreen clump with small pinkish bells; and, finally, there are the dwarfer heaths and rhododendrons. Of the heaths, the well known E. carnea in its various forms is quite invaluable, growing in any soil and almost any situation, and flowering in profusion before even the Kabschia saxifrages venture to push timidly forth. Some of the many forms of the ling, Calluna vulgaris, are dwarf enough to come into the present category —such as vars. aurea, Foxii, minima and tenuis. Of the dwarfest of the vast army of rhododendrons I cannot speak from personal experience, as I have never had a suitable soil for them. Even where this exists, I fancy they do not prove over easy; but they are very lovely things, and—never venture never win. The smallest species includes R. intricatum, R. kamtschaticum, R. prostratum, R. Williamsianum, R. Sargentianum and R. impeditum. It will be seen that the ericaceæ alone supply a whole series of tiny shrubs, most of them of great beauty, and many of them challenging all the resources of the gardeners' art.

A number of other ericaceous things will need mention when we come to the less tiny rock garden shrubs. Of other small shrubs that take their place among the tuft-forming rock plants we have Spiræa decumbens=(S. procumbens) and the closely allied S. Hacquetii, neat little deciduous bushes with flat panicles of white flowers; Hypericum fragile and H. olympicum, with low mounds of glaucous foliage and a glorious wealth of golden bloom in summer; the pretty H. Coris, with smaller leaves and flowers; the tiny and delightful H. cuneatum, with scarlet buds; and so on. There are tiny veronicas, such as V. salicornioides and V. loganioides, like little heaths or cypresses; lovely small daphnes—D. Blagayana, D. petræa, etc.—over which one may lavish much care; various bushy thymes, which need no care at all; and those two excellent minute shrubs, Polygala Chamæbuxus from the Alps, and P. Veyredæ from Spain, which Dr. Stapf considers should be placed in a separate genus and called Chamæbuxus alpestris and C. Veyredæ; and we may finish up this section with that miniature hedgehog, Erinacea pungens, which needs a hot dry corner.

Turning now to trailers and prostrate small shrubs, we may mention first some *quite* prostrate ones, which form little green lakes or waterfalls in the rock garden. One of the loveliest of these is Hypericum reptans, with its great golden blossoms lying on bright green foliage. Linnæa borealis is a most dainty trailer, with twin flowers like little bells—it likes peat and shade. Coprosma Petriei forms a close green mat, very different from the others of the genus. The well known Polygonum vaccinifolium is invaluable, covered with erect spikes of pinkish bloom in autumn. Dryas octopetala, with its delightful big white and gold flowers, is too well known to need more than mention. Daphne Cneorum is (or ought to be) grown by every flower-lover. Empetrum nigrum, the native crowberry of our heaths, makes a fine carpet, but as in Coprosma Petriei the flowers are insignificant. Then the invaluable ericaceæ supply several good carpeters, two native plants, the bearberry, Arctostaphylos Uva-ursi (for dry peat), the tiny cranberry, Oxycoccus palustris (for damp peat); also the may-flower of North America, Epigæa repens, which many gardeners find as difficult as the last two are easy. Some of the alpine willows, too, like Salix reticulata, S. retusa, S. herbacea, are very flat and very pleasing. To come to things that are not quite so carpet-like, the dwarf cotoneasters are hard to beat, with their red berries and leaves colouring in autumn. C. humifusa is the most close-growing of them, and C. adpressa, C. congesta and C. thymæfolia are all first-rate. Lithospermum prostratum needs no praise here, nor the dainty var. prostratus of the rosemary—but this is not over-hardy in some districts. With the mention of some of the beautiful prostrate junipers, like J. Sabina var. humilis and var. tamariscifolia, and that quite prostrate native form which is the J. communis var. nana of botanists but apparently not of Bean's "Trees and Shrubs," we must pass on.

DAPHNE PETRÆA WELL REPAYS A LITTLE CARE.

A WANDERER'S NOTE BOOK

A NEW STATION FOR AQUILEGIA ALPINA.

BETWEEN 7,000ft. and 8,000ft., near the base of the limestone precipices that overlook one of the valleys near the Bernina Pass where you cross from the Engadine into Italy, I was tracking down two primulas, late as it was in mid-July, in the hope that a belated bloom or two might cross my path. The hope was, *mirabile dictu*, fulfilled. Satisfied, I commenced the descent across and down a limestone scree, devoid of all vegetation, that was far-flung from the base of the precipices to the edge of the valley stream hardly discernible far below. Amid this unlikely desolation I stumbled into a small patch of a dozen or so of the alpine columbine. I had failed a day or two previously to light upon the columbine in the entrancing (and to the flower lover doubly entrancing) woods that clothe the south side of the Lake of Sils, and had been unimpressed by the withered blooms that still hung their weary heads in the "Alpine Garden" of Sils-Maria itself. The discovery, therefore, on a high bare scree, in inimitably superb form, of what the prophet of rock gardening called unquestionably the most beautiful plant of the European Alps, was the more unexpected. It then occurred to me that where there were a dozen it was most probable that others would be also; and looking around I descried on the far side of the scree a field of blue, so blue and such a field that in the succeeding days, when one knew where to look, the dark patch on the mountain side was visible from the train as it passed the valley mouth over a crow's mile away.

The field of blue consisted, indeed, of close-packed Aquilegia alpina, at the acme of its perfection—but a bud or two unopened, not a bloom yet flagging. Lugubrious spirits at the Pontresina hotel had informed me that the Swiss soldiery stationed on this frontier during the war had dug up all the aquilegia in the Engadine (I could not think why; were they enraptured into attempted transplantation to their homes, or did they found my colony, near their outposts on the Pass?). A few plants, they said, might still be found in the woods at the base of the Roseg Glacier. To hearten these damp enthusiasts I collected a bouquet of a hundred or so spikes (only to be threatened with arrest by the Cantonal authorities for preventing the seeding of so rare a flower). Which done, I became cool enough for a cold calculation.

The completely blue patch—so blue as to hide at a few yards' distance the coarse white limestone blocks which were the strange compost of the presumably mossy wood-loving columbine—measured 44yds. long by 26yds. broad.

Digitized by Google

Allowing for a clear circle of 6ins. from stem to stem—though for the most part bloom touched bloom—there were in that patch over 40,000 spikes in full bloom; and nearly every spike (15ins. or 18ins. in height), carried three large flowers. The scree faced north. No other vegetation grew upon it. It was sheltered only from the grilling midday sun by the mountain ridge behind. It lay open to all the winds that blew.

All records give A. alpina (as other aquilegias), as a woodland plant. The localities given are "rocky, bushy places," or "the lower light scrub of alpine woods." I read that the alpine columbines "lodge behind bushes on their native hills" and "dislike being battered by winds and weather when coming up." I am enjoined, if I wish to obtain the one—or two—year old plants that alone are worth collecting, to lay my length among the scrub and peer through the herbage, the older plants sending down through deep moss their intractable 2ft. stocks before the fibrous roots splay out. The authoritative prescription for cultivation—"very spongy rich woodland! mixture never parched by sun or worried by wind"—is based on the essentially woodland nature of its best known habitat.

Cultivation in England has proved difficult. Mr. Farrer indeed found it not one of the most difficult, but needing care, especially in the south. He also found that it lost its size in cultivation, and its dazzling blue sank into a steely indigo. The only reliable course for the would-be grower is to collect seed or seedlings with his own hands. What would be the result of an unorthodox treatment based on its brilliance on an unorthodox bare scree? There, at least, the columbine silenced criticism. My collected bouquet lasted well in water, and the wild thought occurred: what a vogue A. alpina would have with the florists could anyone in England coax it into the vigour, floriferousness and beauty of the Bernina colony.

When Mr. Lofthouse saw it (THE GARDEN, 1923, page 662), in its well known home on the south side of the Mont Cenis lake, the blue of its flowers did not come up to his expectation (though admittedly it was somewhat past its best). One had been led, he wrote, to expect a pure sky blue flower in place of the somewhat purplish blue flowers which he found. Purplish! Say rather a soft, clear, deep powder blue. But on the Mont Cenis Mr. Farrer could not resist a qualm as to its form. "Memory is proverbially an excitable thing," he wrote; "yet I cannot but feel that the rarer A. alpina of the Bernese Oberland and the Valais is a trifle larger in flower, solider in substance and more brilliant in the tone of its blue. . . But pure sky blue? The blue of A. alpina is the deep, atmospheric blue on the mountains on a day of racing cloud.

THE SOFT CLEAR BLUE FLOWERS OF AQUILEGIA ALPINA.

LILIUM BULBIFERUM.

My botanical vade-mecum tells me that a botanist by name Chaix, bestowed the specific distinction "croceum" on that form of the Lilium bulbiferum of Linnæus which does not produce bulbils in the axils of stem and leaves. Otherwise I had almost written that bulbiferum was the bulbil-bearing variety of croceum, for croceum is numbered by tens of thousands and bulbiferum by tens only in the thickly-populated dwelling places of this lily. During his wanderings in the Cottian and Maritime Alps, Mr. Farrer stated bulbiferum to be common (though no less beautiful for that), and cheaply obtainable at home. Without further evidence, however, than his book supplies, I am not convinced that he was referring to bulbiferum as distinct from croceum, and in how many catalogues is bulbiferum offered? The gardener who is a live wire ever strains after the best, yet while croceum is a household plant, bulbiferum is a comparative stranger. Granted that in ease croceum is second to none, bulbiferum, also, I am assured, is good and amenable (though "amenable" may have a catch in it, suggesting "amenable to what?"). Bulbiferum's bloom is of a more brilliant red—less flushed with saffron than croceum's orange cup. It is taller, larger in up-standing bloom, carries half a dozen resplendent chalices on each stem to croceum's one or two, and is, in all, so robust as to suggest, not a varietal relationship, but the same plant in a form so vigorous as to be able to reproduce itself by means of the bulbils of the stem which the dwarfer, weaker, less resplendent croceum fails to materialise.

E. ENEVER TODD.

SNAPDRAGONS

SMALL wonder that antirrhinums are popular favourites for bedding and for massing in the foreground of the herbaceous border, for they possess an exceptional number of good points, every one of which is desirable in the plants used for a brilliant summer display. Sturdy and neat, yet not strictly formal, the plants require but little staking or tying except it be the tallest varieties when planted in wind-swept situations. Their hardihood and wonderful immunity from diseases and pests is no small recommendation, and their untiring energy in producing an unbroken succession of flowers for twelve, thirteen and even fourteen weeks is in itself an all-sufficient reason for making great use of them wherever inexpensive occupants of large beds are required.

The custom is to classify antirrhinums in three groups—tall, intermediate and Tom Thumb—but their present-day character necessitates a re-arrangement, for we have real Tom Thumbs which make dense cushion-like plants only 6ins. high, dwarfs from 12ins. to 15ins., intermediates from 18ins. to 24ins., and tall varieties which grow from 2½ft. to 3½ft. The last named produce wonderful spikes of bloom, and compare with lupins for stately effect. The intermediates are of all-round utility, the dwarfs being particularly well adapted for small beds or narrow borders, while the Tom Thumbs provide excellent material for edging large beds to give them a neat and pleasing finish.

Of this last section the colours available are yellow, crimson, rose and white, but of each of the other groups a wide range of colours is open to choice.

"Which is the best antirrhinum?" The question has frequently been asked, but there is no best except to those

Digitized by Google

whose judgment is biased by a special fondness for one colour and lack of appreciation for some other colour.

Yellow flowers appeal to many, but there are some who dislike yellow. Golden Gem is rich and bright, the habit of the plant being intermediate, seldom exceeding 1½ft. in height; but Yellow King is taller by a foot, very clear, and produces fine spikes. The height indicated is the result of quite ordinary cultivation. Growers for exhibition who feed liberally, and also disbud, produce very much taller spikes than 2½ft. About the tallest variety thus far is Monarch, and it is a very fine flower, deep velvety crimson, of splendid size and well set on strong, tapering stalks. Four feet is quite easily obtainable, and really well grown plants of good stock have beaten that by many inches. It may be remarked that such height is quite unnecessary in a bedding plant; admittedly that may be so, but often for the back of a border, for bold, outstanding groups at intervals, and for the back row vases of an exhibit, height, with corresponding massiveness in spike, is sometimes a distinct advantage.

Warrior is perhaps even deeper in colour than Monarch, and it also will grow about 3½ft. in fine style, the individual blossoms being very large, with a waved standard.

Among intermediates there is small need to go beyond a good stock of Empress for a crimson, but it needs to be a good stock, otherwise there may be some little erratic behaviour in regard to colour. Black Prince had a good run, but it is not really a first-rate flower, sears very quickly, and throws a large proportion of scrappy spikes. Its habit is somewhat spindly, and many growers have now discarded it.

Mrs. R. F. Felton is a brilliant flower of wonderful size and arresting colour, and as a scarlet self is very valuable. Its height is about 2ft., and habit is bushy and free. Dobbie's selected stock of coccinea is of bright colour, but the flowers are individually smaller than those of Mrs. R. F. Felton, which is one of Simpson's of Birmingham. The same firm has given us a fine variety in Appleby Matthews. The colour may be described as orange overlaying terra-cotta with a flush of yellow on the frill and a white tube. It belongs to the 2ft. intermediates, and is one of the popular tribe of flame-like varieties which are strikingly effective at a distance. Our Prince is of very similar character, except that it is tall and may outstrip the frequently eulogised Torchlight, which is another of the flame-coloured group.

Apricot and peach shades are of unique charm, and both Prima Donna and The Fawn hold their place in the popular affection, and deservedly so, for they are most delightful flowers, The Fawn being of beautiful shape as well as colour. A new variety of Simpson's is destined to make a strong assault upon the stronghold of these two favourites. It is slightly more pink in its shading, but apricot salmon conveys a good idea of its colour, and although nearly 2ft. in height, it is sturdy enough to enable one to dispense with staking when it is massed in a bed.

In whites, Queen Victoria is a tall grower, Purity is a really good intermediate, and White Queen is serviceable where almost a dwarf (not much over a foot) is required.

There are many pink antirrhinums, but the majority of them have white tubes, and that is somewhat of a drawback in the lighter shades. There is, consequently, an assured welcome for Charm, a real pink self of capital quality. Gloria is a rich rose pink; and in carmine we have Carmine Queen, a beautiful intermediate, and Carmine King, a tall variety in the same colour.

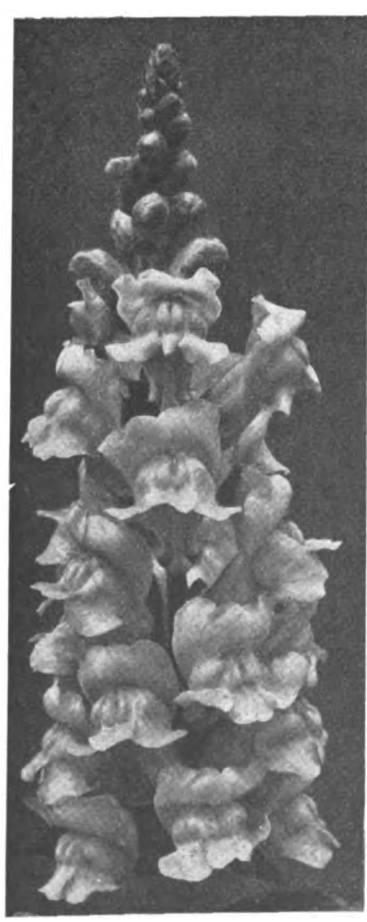
This list by no means covers all the desirable antirrhinums, but Afterglow, Bonfire, Fascination, Sybil Eckford, Silver Queen and Maize Queen have so many times been described and, after all, the best effects are not usually obtainable by using too many colours in close companionship.

So far as planting is concerned, three points should be observed: afford ample room, plant with a trowel—not a dibber—and press the soil very firmly to the roots. The best results are obtainable when the soil has been well cultivated, deeply dug and well manured for a previous crop, but not freshly manured for the antirrhinums. Feeding may then be commenced in the form of surface dressings of a good guano or phosphatic manure as soon as the first signs of buds are noticeable.

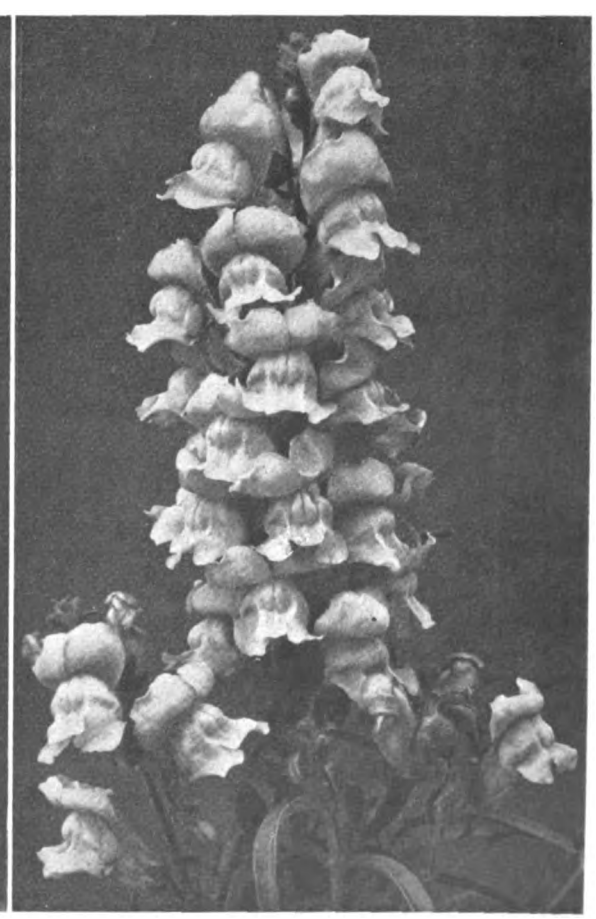
It is much to the benefit of antirrhinums that the first spikes of bloom shall be cut while young, and thenceforward throughout the season seed-pods should be sought and picked off daily. In preference to continuous watering a mulch of light, loose litter will be of great advantage during periods of drought, and as the season advances any plant which appears to be wavering should have its leading branches shortened back to induce fresh growths to break from the base.

The production of spikes for exhibition in cut flower classes involves a certain amount of pinching lateral growths. This should be done on the principle of "little and often," nipping out a few shoots here and there on a plant almost daily rather than severely reducing the growths in one operation, the latter course having a tendency to cause fasciation and irregularity of development through too sudden a diversion of sap through the few remaining channels.

There can be no doubt that for good bold effects in "group" exhibits nothing beats lifting whole plants and wrapping their roots in moss, as this enables the natural character of the plant and its foliage as well as flowers to be displayed. For such exhibits pinching or disbudding is unnecessary and undesirable, for the quantity of bloom will create a better effect than fewer long spikes can do. Before the plants are lifted the ground should be thoroughly drenched, then allowed to drain for a few hours, and after the roots are wrapped get the moss-balls into a shallow tank of water for an hour, and the plants will be good for a two or even three days' show.



PRIMA DONNA.



A GOOD SPIKE OF CRIMSON GLOW.

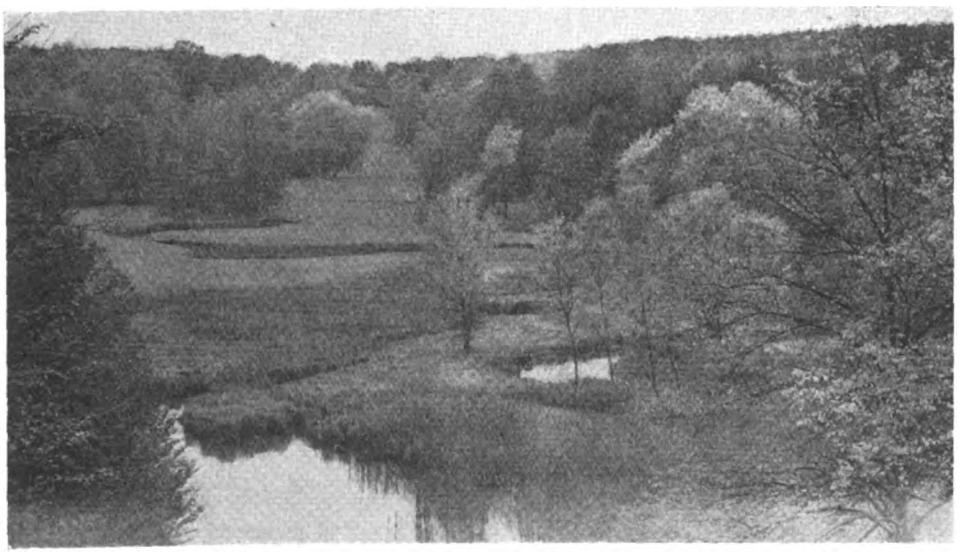
PRUHONICE, THE FAMOUS PARK IN BOHEMIA

AS ONE OF THE LARGEST OF MODERN PARKS, PRUHONICE RANKS HIGH FOR ITS VARIATION OF CHARMING NATURAL SCENERY CREATED FROM MODERN IDEAS OF LANDSCAPE DESIGN, AND ALSO FOR THE FINE COLLECTION OF TREES, SHRUBS AND ALPINES.

THE best-known representative of a naturalisitic style of landscape designer in Central Europe is Prince Pückler-Muskau. During his frequent and long visits to England at the beginning of the last century he became deeply impressed with the landscape style used at this period, and especially with the classical works of Repton. On his large estate at Muskau on the Neisse, in a rather poor part of Germany called the Lausitz, a little north of the large town of Görlitz, he, in 1815, started to carry into effect the impressions he received in England. But he was in no way an imitator; he was a great but somewhat queer personality of a high artistic standing. As his little booklet, "Andeutungen über Landschaftsgärtnerei," clearly shows, he had "a conception of naturalistic design which worthily matched the work of Repton and Price." He was not the first and only one who accepted the ideas of landscape creation of the end of the eighteenth century. C. C. L. Hirchfeld in his fairly comprehensive work on the theory of landscape design (1779-85) had already preached this gospel. He was the real pupil of Pope and Brown, and his book is full of the romantic schemes of his time. What Repton did in England, Sckell, the creator of the English Garden at Munich, and Prince Pückler did for a more rational development of landscape gardening in Germany. Pückler's work at Muskau is still well preserved. The place now belongs to Count Arnim, who, with the assistance of Mr. R. Lauche, takes the greatest care of it.

But, after all, Muskau does not and cannot show the German ideas of a park of the twentieth century. Those modern ideas of a naturalistic scheme of park design are, in my opinion, best represented by the work of Count Ernst Silva Tarouca at Pruhonice, near Prague, in Bohemia. This famous park, of which the young Czechoslovak Republic ought to be very proud, is still too little known even in Germany and in England. Count Silva is a born artist with regard to landscape design. As the owner of a great estate he commenced his work in 1888 without any knowledge of the great English parks, or even the work of Prince Pückler. He was an enthusiastic sportsman, and on his hunting trips he became well acquainted with natural scenery, and with the trees and flowers of Central Europe. On his own grounds he found everything he needed to develop and create landscape effects in the grand manner. Nature's striking examples did, however, serve him as inspiration. He was sensitive enough to feel what characters were latent in the natural scenes with their hidden beauties on which he was called to work.

VIEW FROM THE CASTLE TO THE SOUTH OVER THE "SCHLOFSTEICH."



ONE OF THE BEST VISTAS, WITH SILVER POPLARS FORMING THE FOREGROUND.

Nobody who goes by train or car from Prague to Pruhonice expects to find there a landscape of great natural beauty. The country is rather flat, and covered with well kept fields, indicating a rich, heavy soil—an ideal place for farming. Even after his arrival at the small village of Pruhonice the traveller sees almost no sign of a large park. But as soon as he steps into the court on the southern side of the castle a great surprise waits for him. The first of a sequence of grand landscape scenes opens upon him. Its real grandeur cannot be shown through the medium of a photograph, but, nevertheless, the illustrations give a rather good idea of the character of the landscape with the pond in the foreground about 60ft. below.

The whole park at Pruhonice forms a series of valleys surrounded by wooded slopes with wide, green lawns and several ponds of different size connected by a small rivulet. These form each for itself a natural scene of a distinct character which has been carefully studied by Count Silva in order to treat them in a way to give each a definite individuality, to develop each important view as a pictorial composition. Pruhonice, in consequence of its more individualistic treatment, is very different from Muskau. To a very great extent Count Silva has, at least in certain parts of his park, made use of foreign trees and shrubs, while Prince Pückler scarcely planted anything else than the trees common to Central Europe.

The formation of certain landscape scenes by means of trees from parts of the northern temperate zone other than Europe is often to be met with in our parks, but seldom is it attempted on such a large scale. Most of the plantings are still too young to show the real effect the artist is trying for. One scene especially is very promising. A very large deep

Digitized by Google

pond is surrounded by rather steep slopes. Those facing south form an imposing natural rock garden quite different from the one near the castle mentioned later. The rocks are rather barren, and it proved almost impossible to start plant growth on them. Nevertheless, large groups of Picea pungens, Abies concolor and Pinus austriaca are slowly growing up, while in the rich bottomland on the shores of the pond Douglas firs, Engelmann spruces and other North American and Asiatic conifers thrive luxuriantly. The same is the case with the conifers planted on the slopes facing north. I saw them first almost twenty years ago, and on every new visit to Pruhonice I am surprised how quickly those firs, spruces, pines and arbor-vitæs and cypresses are growing. About ten years from now one may be able to give a good impression of this scene even on a photograph.

The variation of the natural scenes at Pruhonice is one of the great features of this park. I cannot describe or even mention them in detail. Some of them I shall, however, point out. Beneath the castle, which has been built by the owner on the foundations of an old one, a large, picturesque, natural rock stretches itself for half a mile along the eastern side of the pond. Our picture shows a small part of this immense rockery which once comprised the richest collection of alpine plants on the Continent. Unfortunately, since the war most of the finest plants have been lost. Count Silva has been absent from his place for years, and at present he has not means at his command to keep up the rock garden as he used to. It was once his main hobby, and he could really be proud of it. Only the hardiest ones survive, and it is really astonishing how many plants have become almost naturalised. There are, for instance, still large patches of several acæna, like argentea or Buchananii; even acantholimon species stood the hardships well. Alyssum argenteum, of course, and some androsace, and Anthemis Aizoon, Arabis alpina, Armeria cæspitosa, various aubrietias and campanulas, Cerastium Biebersteinii and some nice dianthus hardly need any care. Besides these one still frequently meets between the rocks such species as Draba aizoides, Erodium Manescavi, Geranium lancastriense, Geum coccineum, Horminum pyrenaicum, Leontopodium alpinum, Lithospermum purpureo-cœruleum, Matthiola vallesiaca, Phyteuma campanuloides, a good many primulas, Satureia montana, Saponaria ocymoides, Saxifragas Elizabethæ, longifolia, marginata, muscoides and sancta, species of sedum and sempervivum, Thymus serpyllum, Townsendia Wilcoxiana, Veronicas argentea and gentianoides. A good many interesting dwarf shrubs have found convenient sheltered places among the rocks. Rhododendron yedoense and several of the Chinese species related to intricatum are growing freely. Also some of the larger types, such as R. Smirnowii, and of course, all the European species and their hybrids. Many evergreen forms of Chinese cotoneasters form broad clumps, covered with their beautiful red fruits for many months, as, for instance, C. Dammeri, C. adpressa and some forms not yet identified botanically, of which I sent the seeds from north-western Yunnan ten years ago.

The collection of foreign trees and shrubs at Pruhonice is very large. In almost every part of the big area where a suitable place could be found rare plants have been placed. A few years ago Count Tarouca commenced a big evergreen plantation of rare conifers and a great many broad-leaved species. Most of them survived the long and severe winter of 1923 to 1924 without any real damage. Viburnum rhytidophyllum, V. utile, Berberis Julianæ, B. Gagnepainii, B. Hookeri, Stranvæsia Davidiana, several forms of skimmia, a great many fine varieties of Ilex Aquifolium, Pyracantha angustifolia, Photinia glabra, Phillyrea decora, Daphniphyllum macropodum, Cistus laurifolius, and even such plants as Corokia Cotoneaster, Castanopsis chrysophylla and Trochodendron aralioides seem to do well, but are still too young to judge of their real hardiness. Prunus Laurocerasus schipkænsis, kalmia, Lonicera pileata, and such half-evergreens as Quercus pseudo-turneri, kœhnei, and also the forms of the hybrid Q. hispanica known as Lucombeana and fulhamensis are quite hardy.

But, after all, the most important feature of Pruhonice is its artistic value. It is our largest modern park, covering a surface of more than 500 acres, and I do not think that there is even in England a modern creation of landscape design of equal artistic value. The park needs, of course, ten to twenty years more to develop fully its most characteristic scenes; and it is, therefore, a great pity that under the prevailing

THE CASTLE SEEN FROM THE SOUTH-WEST.

THE LARGE PICTURESQUE AND NATURAL ROCK GARDEN WHICH CONTAINS A RICH COLLECTION OF ALPINE PLANTS.

Digitized by Google

circumstances it may never become finished. If Count Silva cannot do it out of his own means the Government ought to take it over as a national park and to provide the necessary money for its upkeep and finish. The Czechoslovaks are a garden-loving people. Pruhonice is not far from their capital, and it ought to become a well kept public park, and not to be allowed to fall to decay if it cannot be kept and finished by its owner. It is always difficult to preserve such great living works of landscape art, but they are among the most precious treasures a country can have.

CAMILLO SCHNEIDER.

THE MANURE PROBLEM

PROPRIETARY BRANDS OF FERTILISERS.

WHEN study has so far advanced that a tolerably clear idea of the requirements of plants has been acquired, there still remains the difficult question of ascertaining what are the important deficiencies in the soil with which we have to deal. The knowledge that plants require potash, nitrogen, phosphoric acid, lime, etc., is helpful to a point, and supplemented with the information that nitrate of soda and sulphate of ammonia are rich in nitrogen, that sulphate of potash is the best form in which to apply potash, and that one chemical is adapted for light sandy soils and another for clay, we have a combination of facts at our finger tips which, theoretically, should make us expert plant feeders. In point of fact, however, there is every possibility of going grievously astray unless the soil to be dealt with is so thoroughly understood that the required chemicals can be applied in a proportion that will make up the deficiency without an unbalancing effect upon the existing properties in the soil.

Reliance upon soil analysis may be wise or otherwise, but there is a tremendous risk that the report upon a few pounds of soil taken in handfuls from various parts of a garden will bear very small resemblance to the actual chemical character of the garden as a rooting medium for plants and crops. Analysis of a single small sample of soil should therefore seldom be considered sufficient reason for putting implicit faith in the capability of a heavy dressing of this chemical or that. As a matter of fact, it is the rule rather than the exception that one chemical fertiliser should be supported or followed by another.

The commercial grower with large acreage may economically and with advantage utilise chemicals separately and individually, but all things considered it is of greater advantage to the private gardener and amateur to use a compound fertiliser or a manure of more or less complete character.

There is always this advantage in a proprietary fertiliser—it is blended in a proper manner by a firm possessing all the equipment necessary to test the quality of the component parts and to blend them thoroughly. The production of such fertilisers is the work of fully qualified chemists: it has to be, for no inferior and unreliable brand of garden fertiliser can for any length of time endure in face of competition as keen as can be matched by any commodity in trade. That the range of fertilisers on offer to the public is of bewildering extent is itself high testimony to their quality, for a poor and unsatisfactory brand would speedily be elbowed off the market by the crowd of tested and tried fertilisers that have an established reputation.

Not all proprietary fertilisers are equally adapted for every purpose. There are certain brands I have used intermittently for a period of three dozen years, and within that time I have cultivated many gardens of widely differing character, and in some cases the the fertilisers I like best have had to stand aside in favour of others which were better suited to the particular requirements of the gardens concerned. The question of humus must always be carefully considered; and, on the one hand, a harsh, brashy or gravelly soil, or, on the other hand, a stiff, stubborn clay, require a bulky vegetable or even animal-refuse compound rather than a concentrated chemical preparation.

Hop manure is of very great value on gravel, chalk, clay or dry sand, especially where stable manure is scarce. Wakeley's is a well known name in connection with hop manure, and as this particular brand is reinforced with useful chemicals it is of sound value and great utility.

Other good hop manures are on the market, the famous firm of Abol, Limited, have a good line of their own. Maskell's is another, and other names might be added, but my purpose is not to advertise makers but rather to indicate the particular purposes for which different kinds of proprietary manures are suitable. Hop manure would not be my choice for an old black-soiled garden already surcharged with humus, but new gardens and those where the soil is of a "hungry" character are greatly benefited by it.

Fish and meat meal manures are also good for new and somewhat dry soils. The Humber Fishing and Fish Manure Co., produce a capital manure, and Messrs. Robinson Bros., Limited, West Bromwich, manufacture a fertiliser which contains a large proportion of animal fat and bone which is of lasting value.

Wool waste, combined with dried and pulverised sheep's manure, makes a rich, quick acting yet long-standing soil enricher, for the particles of wool not only themselves contain valuable properties, but are also of sufficiently absorbent character to take up, and hold the properties of the actual manure as they dissolve. Wellson's plant food is a compound of this character prepared by efficient grinding and mixing machines, and consistently turned out to a high standard of excellence. Messrs. Willis Bros., Harpenden, also handle wool waste products, which are extremely useful for opening up stubborn clay soil, or improving the moisture-holding powers of a stony sand.

Quite a large number of flowering plants, as well as the root crops among vegetables, like a good, rich soil, but are not improved by being transplanted (or sown in the case of seeds) in freshly manured soil. On this account it is frequently desirable to apply fertilisers at the time of autumn digging, that they may lose their "fire" before the roots come in direct contact with them. Rapidly soluble chemicals cannot economically be buried in soil which is to lie vacant throughout winter and early spring, but here again manufacturers come to our aid with preparations which are admirably adapted for the purpose. Stonehouse "Soil Enricher," Robinson Bros.' "Multiple," H. P. Tripps' "Tripple" Fertiliser, Bull's Plant Food, Abol Horticultural Fertiliser, native guano, various brands of blood and bone manure, dried sewage, and the hoof and horn fertilisers belong to this class, being highly nutritious, for the most part gradual in their pace of conversion or solubility, and in all respects suitable for enrichment of soils which are well supplied with humus, but require replenishment of phosphates, potash, and a slowly soluble form of nitrogen.

Thus far, the point of consideration has been the improvement of the soil in regard to its stores of staple plant foods, all the substances referred to or indicated being suitable for digging in, either in autumn or early spring. Not half of the fertilisers of this character have been individually named, but it will be found that such firms as G. H. Richards, Casein Products, The Key Fertiliser Co., Briton Ferry Chemical and Manure Works, Lawes' Chemical Manure Co., The Acme Chemical Co., Garden Supplies, Limited, H. Richardson and Co., and still other firms have among their brands one or more which by general usage rather than scientific accuracy, are termed organic fertilisers, and these are the kinds for digging in, and provided a choice is made with due regard to whether or not the soil requires humus, safety and satisfaction are pretty sure.

There still remains the very important problem of selection of tonics and stimulants to be applied during the height of the productive season either in the form of dry top-dressings or as liquid manure.

For pot plants, the most convenient and economical method of applying tonics is that of watering. Top-dressing big batches of plants in pots with

Digitized by Google

spoonfuls of powder is an irksome task, while there is always the danger that at the next watering too much of the undissolved chemicals will be washed to the crowns or stems of the plants to do mischief. In the case of beds, borders, vegetable quarters, etc., it is frequently safer periodically to top-dress with dry fertiliser and hoe it in; the hoeing always benefits, and on the other hand, watering big areas is a risky business to start upon, because intermittent watering during prolonged drought is detrimental rather than beneficial, and regular watering may be too great an undertaking. A limited quantity of liquid fertiliser is inadequate moisture for the soil, and a thorough soaking may easily dilute the fertiliser to such an extent that its benefits are nullified.

Numerous as the highly concentrated fertilisers for the purpose under present consideration may be, there are some which have stood the test of time, and have survived the continuous bombardment of competitive lines, the names of such scarcely need mention except by way of appreciative compliment. Clay's Fertiliser, Ichthemic Guano, Canary Guano, Thomson's Manure, require no eulogy; they have been life-long helpmates. There are, nevertheless, various brands which are of comparatively recent introduction, but which have to their undoubted credit the solid fact that they have made progress, sufficient proof in itself that they are good; else they, like some others, the names of which it is not worth while to recall, would have gone under, after brief but futile assaults upon the strongholds of the aforementioned old servants. Carmona, Abunda, and other names occur to mind, and the results of their use are pleasing, while still the numbers grow, and new firms enter the field: Casein Products, Plantora, Key Fertilisers, Briton Ferry, Vickers, being names of recently acquired and growing reputation. The question is sometimes asked whether this multitude of proprietary fertilisers is really required; my answer is that their continued existence proves their need and utility, for in the severity of present-day competition, the unwanted and the incompetent cannot stand.

The wide range of fertilisers is a boon to the grower, because it provides easy means of varying the menu for his plants and crops, and rest assured, however pleasing the results of a certain fertiliser may be, there comes a time when plants and soil benefit by a change, and the wise cultivator is observant of that fact. For my part, even in a single season, I should prefer to use two kinds of fertilisers at intervals, than adhere to one the whole season through.

Plant feeding and soil enriching is an intricate problem, requiring an immense amount of study. Manufacturers have helped greatly by compounding well balanced fertilisers, but there is yet a possibility open to those who possess the necessary scientific knowledge, to help still further by telling candidly for what particular purposes and soils their individual brands are most serviceable. We fully realise the aim of the manufacturer is to sell, and not to narrow the limits of his market by quoting the minimum of serviceability of his productions, but the grower has learned just enough to know that different soils, different plants and crops, and different seasons of the year require different kinds of manures or fertilisers, and rather than narrow down the sphere of utility the manufacturer will foster increased demand by guiding the user in the difficult matter of using a particular fertiliser for a particular purpose. That will make for progress, while the claim of all to be competent for all purposes tends to bewilder if it does not actually mislead.

L. I. ATRIS.

DEAR HARBINGER

BY HALLIWELL SUTCLIFFE.

SHE is almost due, gowned in the lilac mauve beloved of old-time gentlewomen. Some name her the Chinese primula, others the Cashmere primrose. The wise, book-learned men have a Latin name for her, which I forget with great patience every time I hear it.

She is, as the Dale counts matters, a new-comer in our midst. She has not been settled here, that is, for as long as three hundred years or over. But she knows all about us, because she finds the same limestone highlands that she has known for centuries untold. Sometimes I fancy she smiles tolerantly as she listens to the gnarled yew trees in the garden, and hears them boast that they were here when Senlac Field was lost and won. In the far-off land of her ancestry the trees whispered o' nights of emperors whose dynasty was old when Senlac's warriors were binding the raw wounds of battle.

A FREE FLOWERING CLUMP OF THE CASHMERE PRIMROSE.

This dear harbinger of flower-tide is pushing up the crowns of bloom that soon will make witchery of our garden ways. Snowdrops and aconites have sent their banners out against the winter's spite. Soon the Cashmere primrose will carry the blithe standard forward.

"Harbinger" she is to me, and, I fancy, if she were asked, that she would admit my right to give her a pet name of my own. Many years have passed since a village schoolmaster higher up the Dale gave me my first root. Since then I have been constant to her service, until now you are never sure in what odd nook and corner a clump of mauve blossom may shine through the nipping east wind days. "Plants, like humans, know when you love them," an old gardener said to me one day; "and, once they know that, you can do almost anything with them."

That has been my experience of Harbinger. I have planted her in the wind-swept open, in the little strip of woodland by the stream; and in shade or sun she thrives, eager to humour my caprices. Like all courageous optimists, she is apt to think the best of those subtly treacherous days that come in mid-December, when warm airs blow and gnats come out of their crannies. For this reason the safest quarters for her are in positions slightly sheltered, but not too secluded from nip of the pessimist winds that check her hopefulness.

Harbinger loves to be tucked up in limestone pockets with moistish soil for her feet; and that is fortunate, for the round heads of bloom, showing against the soft greys of the stone, have a beauty not to be described by any pen.

A true-hearted gardener must always have something of the evangelist about him. In all the years that Harbinger and I have shared, I can remember no one who, seeing her in full bridal dress, has failed to yield instantly to her strange, appealing charm. She is, in some deep sense of the word, a mystic flower, and lays a happy spell on men. She is, too, a this world's creature, brave and buoyant though winter whistles down the steeps. And that is why one would like more folk to be acquainted with Dear Harbinger.

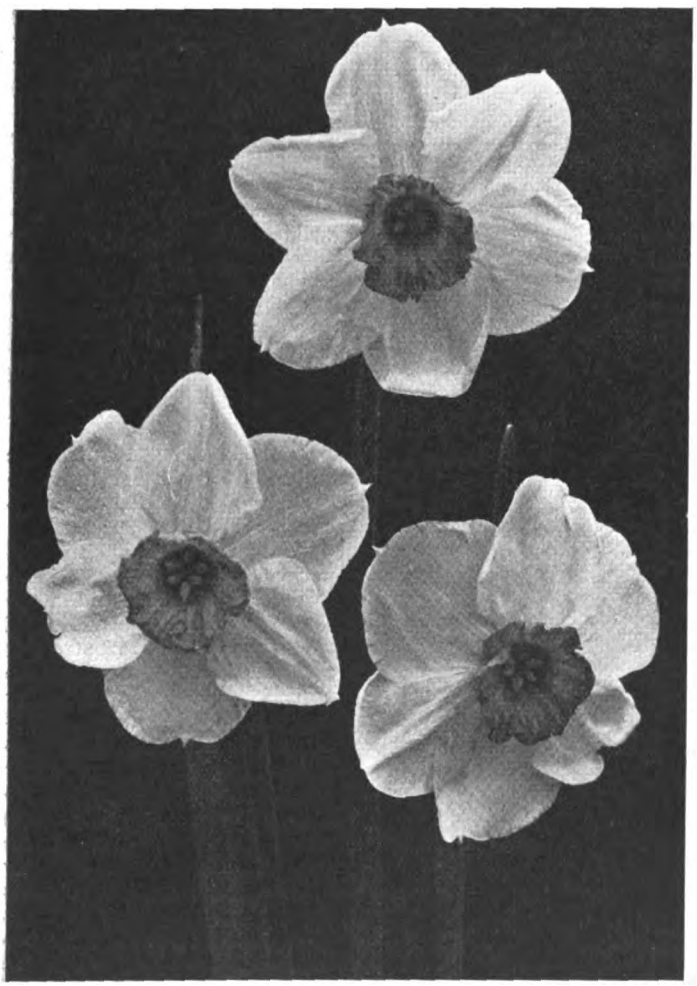
THE LONDON DAFFODIL SHOW

WHEN attending a flower show, and particularly a special flower show such as that under notice, we usually endeavour to place ourselves in the position of a flower lover visiting such a show for the first time or, at least, after a considerable interval. On April 15th and 16th the first impressions of such a person must have been disappointing, as, immediately on entering the Royal Horticultural Society's Hall at Vincent Square, primroses and polyanthuses met the eye—excellent flowers and worthy of unstinted admiration; but they were not daffodils—immediately above and beyond the primroses were carnations, lovely fragrant carnations, but still no proper substitute for daffodils. Having rounded the corner of primroses and carnations, so to speak, one was confronted with beggarly empty tables. Messrs. Barr and Sons staged over two hundred distinct varieties in goodly vases. The dainty little flowers of Silver Cycle did not find favour with the committee, but were greatly admired in the collection. Besides its grace and charm of form, it is the first cyclamineus bicolor hybrid that they have shown. Warwick, a yellow trumpet; Nereus, a somewhat similar bloom but of richer colouring, with a widely open, frilled tube; Basilia, of similar form but lovely primrose yellow; Fiery Monarch, a large incomparabilis with a brilliant corona; and St. Olaf, a starry Leedsii of delicate beauty, are the names of only a few of the delightful sorts to be seen. But lovely as these were, they were equalled and at times surpassed by some of the unnamed seedlings The large Barrii flowers, both with white and with yellow perianths, were wondrously beautiful. while in the centre of the group there was a vase of the splendid Fortune, a large incomparabilis with a yellow perianth and lovely orange corona.

Bath's Flame, a Barrii variety with a cupped, red-rimmed corona, was the outstanding sort in the collection of Messrs. R. H. Bath, Limited. Lord Kitchener, with a pale primrose tube; The Marquis, Dominion, Golden Goblet and Early Gold, four rich yellow trumpets; with Buttermilk and Inglescombe, doubles, were also of great merit.

High quality was fully evidenced in a large collection arranged by Messrs. J. R. Pearson and Sons; while the grouping of a few selected varieties was an agreeable change from the conventional method. The massed blooms of Marshlight, Brilliancy and Sunrise were



N. LADY DIANA MANNERS, AN EXCELLENT BARRII VARIETY.

THE TWIN-FLOWERED TAZETTA, N. KINGCROFT.

Then one saw the glorious arrays of daffodils of all possible forms and colouring so generously displayed by the chief trade growers, and realised that, after all, it really was a daffodil show.

Although it was, nominally, a competitive show, these wonderful groups of cut blooms were, as so often happens, the making of the show, and no praise can be too high for them. The high quality can be assessed from the fact that four gold medals were awarded. The recipients were Messrs. Barr and Sons, Messrs. R. H. Bath, Limited, Mr. J. L. Richardson, and the Donard Nursery Company. A whole number of THE GARDEN might be filled with appreciations and descriptions of the thousands of admirable blooms which made up these monster exhibits.

The large trumpet daffodils shown by Mr. J. L. Richardson included Ivorine, Goldbeater, Master Robert, Sergeant Murphy, Michael and Loyalist, the first a white variety and the remainder of rich yellow shades. Queen of the North and White Star are two of his best Leedsii, while Firetail and Crœsus of the Barrii section possessed brilliant coronas.

In the Donard collection it was such as Eskimo, Silver Fox, Tenedos, Everest, Lady Sackville and Phantasy, in pure white or sulphur shade; and Gog, Magog and March Wind, of deep yellow colour, among the trumpet daffodils that attracted first attention. For brilliance of colouring, Crœsus, Carnival, Dosoris and Sunrise were excellent; delightful. Other sorts which attracted special attention were Moira O'Neill a bicolor trumpet with a primrose tube; Sanctity, a pendulous white trumpet; Fairy, yellow; Bernardino, Potentate and Thorkel, Barrii varieties; and, in The Pearl and Argent, two fine doubles.

Sarchedon, shown by Mr. J. W. Barr, was the finest poeticus variety in the Show. Alope, a large trumpet with a deep primrose perianth and richer tube, possesses great charm; St. Hilda, yellow trumpet; St. Hywin, a giant Leedsii with an attractive frilled corona; Treserve, a gigantic yellow trumpet; and Silver Fleece, are the names of a few of his novelties.

Smaller but interesting collections were contributed by Messrs. Cartwright and

Digitized by Google

Goodwin, 'The Welsh Bulb' Fields, Mr. W. F. M. Copeland, Mr. W. D. Fownes, and Mr. Thornton.

With very few exceptions the competitive classes did not induce many exhibits as might have been expected. In the open classes which required three blooms each of twelve varieties, Mr. J. L. Richardson and the Donard Nursery Company were awarded two first prizes. The latter's yellow trumpets were particularly good. The chief varieties were Clarion, Grenadier and Gorgeous. In this class Mr. Richardson and Mr. F. H. Chapman were placed equal second. Of Mr. Richardson's first prize blooms, Orange Glow, Brightness, The President (incomparabilis), Firetail, Queen of Hearts, Crimson Braid (Barrii), were the best.

In the next classes, requiring three blooms each of six varieties, Mr. Richardson won six first prizes with splendid vases of such sorts as White Dame, Atalanta (white trumpets), Mrs. W. Christie Miller (bicolor trumpet), Orange Glow, Brightness (yellow incomparabilis), Pedestal, The President (bicolor incomparabilis), Queen of Hearts, Lady Moore (bicolor Barrii), Irish Peach, Tenedos (large Leedsii). Mr. Chapman, whose best were Ossa, Formidable and Yukon, was first with yellow trumpets. Showing six seedlings, Mr. Copeland was first with Triandrus and with Oranges and Lemons, Meringues and Irene Copeland, was equally successful with doubles.

The open classes for new varieties were the most successful in the Show. The premier prize was won by Mr. P. D. Williams, with twelve magnificent varieties, which included St. Agnes, a giant Leedsii with a delightful crested rim to the corona; Kilter, a brilliant Barrii; Theodore, a bicolor Barrii; and some excellent seedlings. Dr. N. Y. Lower, who was second, included in John Peel, a lovely Barrii with a pink sheen on the perianth and a reddish orange corona. Beauty of Radnor and Rewa were also of great merit. In the class for six varieties, also raised by the exhibitor, the Rev. A. R. Meyer was first with unnamed seedlings; and the Rev. G. T. Pearce was second. The best three shown by the Donard Nursery Company were also unnamed.

Mr. P. D. Williams won the first prize in the very strong class for twelve varieties not in commerce. Here he included magnificent vases of Kilter, Nelly and Kenegie (Barrii), and Miriam, a sulphur yellow trumpet. Mr. Richardson, who was second, showed the rich yellow trumpet, Golden Ingot, and Sunset Glow, a brilliant Barrii. The Rev. H. R. Meyer had the best six and Mr. Copeland the best three varieties; while Major Churcher was first in the novices' class.

The classes for single blooms of the different sections or sub-sections were generally well filled. Mr. P. D. Williams and Mr. Richardson were first in four classes. Mr. Watts was first in two, and Mr. W. Welshman, Mr. Copeland and the Donard Nursery Company each won a first prize.

The amateurs' classes were poorly represented. Miss K. M. Hinchliff, Worlington House, Instow, was the chief exhibitor in the first section; and in the other, the Rev. G. Pearce, Creed Rectory, Granpound, Cornwall, won most of the first prizes, Miss Violet Warren, The Quinta, Canterbury, was first in two classes.

The three bowls of daffodils were poor attempts, and no one seemed to exhibit a basket of blooms.

NEW DAFFODILS.

BEERSHEBA.—This is a large, white trumpet daffodil of substantial make and a long tube lined to the base with a suggestion of yellow at the junction with the perianth. Award of merit. Shown by Mr. J. L. Richardson.

DAWSON CITY.—A handsome yellow trumpet daffodil. The perianth is shapely and the cylindrical tube is exceptionally long. Award of merit. Shown by Messrs. R. H. Bath, Limited.

FANNY CURREY.—A delicately beautiful giant Leedsii bloom of paper white colour. The widely expanded, frilled corona is prettily fringed with pink. As only three blooms were shown, an award of merit could not be granted. Preliminary commendation. Shown by Mr. J. L. Richardson.

HADES.—The application of this name is not readily apparent. It is, however, a beautiful Barrii variety. The large star-shaped perianth is of pale primrose colour and the basin-shaped corona is a deep cardinal. Preliminary commendation. Shown by Mr. J. L. Richardson.

JUBILANT.—This is a magnificent giant incomparabilis variety. The perianth is rich yellow and the large tube is a deeper shade of the same colour. Award of merit. Shown by Mr. P. D. Williams.

KINGCROFT.—This was certainly one of the best novelties in the Show. It is a twin-flowered tazetta bearing blooms the size of a small pheasant's eye narcissus. The perfectly round perianth is white, and the regular corona is a bright orange. The blooms are sweetly scented. Award of merit. Shown by Mr. P. D. Williams.

LADY DIANA MANNERS.—We are inclined to the opinion that this was the best Barrii variety with a white perianth in the Show. The blooms are large, perfectly round and possess exceptional substance. The broad corona is of deep yellow colour, heavily margined with fiery orange. It is recommended for garden decoration and for market purposes. Award of merit. Shown by Messrs. J. E. White and Sons.

YELLOW JACKET. — There were several varieties among the eighteen before the committee which we should have expected to receive an award in preference to this. Opinions were divided as to which division it should be placed in, and with reason. It is a small self yellow flower with a poor type perianth and neat little corona, which seems to belong to the Barrii division. Award of merit. Shown by Mr. C. A. Jardine.

THE INTERNATIONAL SHOW AT HAARLEM

IN the grounds of Groenendaal Park in the small and quaint village of Heemstede, near Haarlem, is laid out one of the most magnificent flower shows in perfectly natural and charming surroundings. Over forty acres of what was formerly woodland pasture, with gentle undulating slopes broken at intervals by the windings of tiny streams, have been planted with spring flowers. It is fifteen years since the last great international exhibition at Haarlem, and 1910 has been easily eclipsed by the present one. Within these years enormous changes have taken place in horticulture throughout the world, with the introduction of new plants, and it is one of the main purposes of the Show that it exists for the study of the many new species and varieties that have entered the bulb world during that period. In addition one realises how little Dutch horticulture has to learn in connection with bulb growing. Over 2,500,000 bulbs were planted in the area last autumn, and the mass of bloom this spring stands as testimony to the enterprise and skill of the many Dutch firms engaged in the industry.

In front of the spacious exhibition hall, wherein are being held special shows of flowers and shrubs in season, are laid out numerous beds of narcissi, tulips and hyacinths. The method of planting these beds may be noted *en passant*. The beds are well filled, yet the individuality of each plant is retained. The spacing is such that the foliage has a sufficiency of room to carry out the necessary life processes of the plant. Throughout the whole lay-out of the exhibition one meets these beds at every turn, providing an array of bloom and a perfect kaleidoscopic effect in colour which would be difficult to equal. Whites, yellows, blues of all shades, and reds of the tulips and hyacinths, combined with the yellow heads of the daffodils nodding and dancing on their long stems, peeping from a mass of light green foliage, produce a blend of colour which the artist would find exceedingly difficult to portray. Holland well deserves its name as 'The Garden of Europe," for truly no other country can produce such a wealth of bloom and colour in April and May as the land of the dykes and windmills.

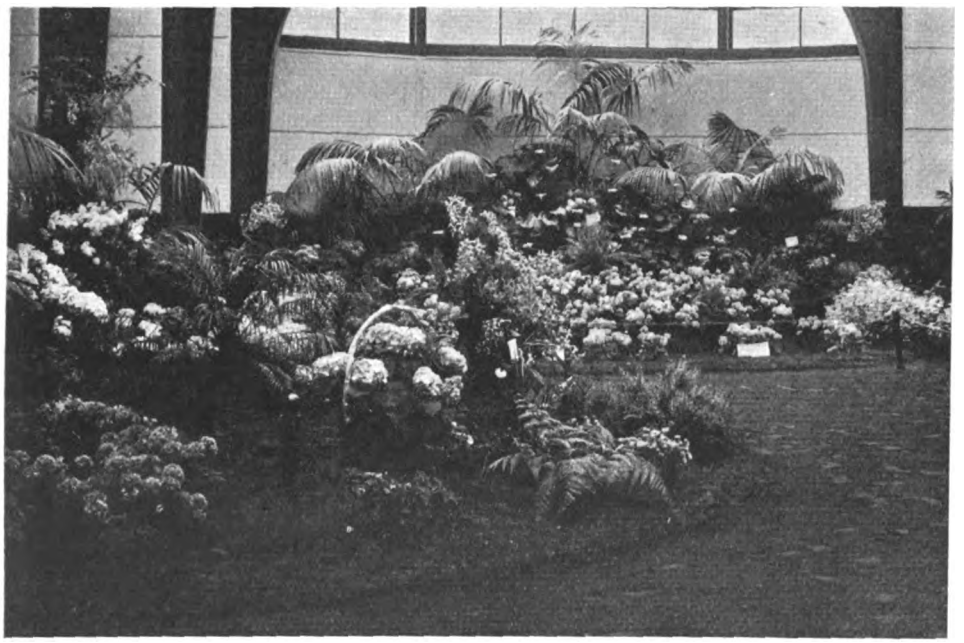
In addition to beds containing hyacinths there is a number filled with shrubs. The planting of the latter has been largely carried out by the firm of W. Keessen and Sons, "Terra Nova," Aalsmeer. The collection is a representative one containing cotoneasters, berberises, osmanthus, viburnums, stranvæsias, etc., all of which appear to thrive exceedingly in the sandy soil. One bed close by calls for a word of praise, containing well fruited specimens of Ilex pyramidalis, which lends a touch of pleasant colour to the surroundings. Many beds of ornamental conifers, including new species from China, and of rhododendrons, which will be in their full glory next month, have also been set out by this firm and many others.

Near to the industrial department of the exhibition, which is of much interest, and contains a section dealing with pathological problems met with in bulb cultivation, is a small rock garden laid out by Messrs. Sengesskamp, Laren, N.H. The arrangement is good and gives one the idea of spaciousness. The subjects are well chosen, and produce the maximum of effect. Many choice alpines fill the crevices and niches in the rocks, while splashes of a bolder colour appear here and there through judicious mass planting of spreading varieties. Dwarf shrubs are planted at intervals between the more trailing alpines, while a background of tall piceas completes the exhibit. Other two rock gardens are to be met with in the outlying parts, one designed by Messrs. A. Koper, Heemstede, the other by Messrs. Kweekerij, Moerheim. The former, laid out in woodland intersected by many winding paths, contains numerous interesting alpines, such as Raoulia australis (the "vegetable sheep" of New Zealand), saxifrages, primulas and dwarf shrubs. The latter is laid out on a mound in a series of banks. The idea is a novel one, and the plants are shown off to the best possible advantage. Stretching to the left of the exhibition hall there lies a very fine formal garden designed and executed by the Dutch Bulb Exporters' Association. The beds, planted up with tulips and hyacinths, are laid out in squares and rectangles. In the centre of the garden, which is enclosed by an evergreen hedge, stands a single-spray fountain. Undoubtedly one of the best gardens is that laid out by Messrs. Van Tubergen of Haarlem. The natural surroundings have been taken advantage of to the full and many choice woodland plants have found a place beneath the original trees of the park. Masses of Anemone fulgens and the St. Bavo strain lend a vivid touch of colour to the scene, which is mellowed

Digitized by Google

by the yellows of the daffodils and the more delicate shades of the hyacinths. Erythroniums, bulbocodiums, dwarf narcissi and eranthis, also add considerably to the general effect. Along the streamside a border containing hyacinths and the ever graceful water lily tulip, T. Kaufmanniana Gaiety, whose fine blooms are carried on stems barely an inch in height, with bushes of Mahonia Bealei at intervals, was also laid out by this firm. The outside exhibits cannot be passed over without reference to the excellent show of topiary work by Messrs. Helverda and Co., Aalsmeer, and also the numerous small fruit gardens laid out by firms engaged in fruit culture throughout Holland.

The value of these outside exhibits undoubtedly lies in demonstrating the excellent effects which are to be obtained by the judicious planting of spring-flowering bulbs, and also from the placing of selected species of shrubs and conifers. One recognises the importance of mass planting to secure good colour effects, and also the species and varieties which can best be planted together so as to obtain a harmonious colour scheme. Moreover, the qualities and characteristics of recent acquisitions can be studied first hand, which is of great advantage to those interested in the commercial aspect.



IN THE EXHIBITION HALL DURING THE SECOND SPECIAL SHOW

Inside the exhibition hall a magnificent collection of flowering shrubs, hydrangeas, azaleas, rhododendrons and roses, backed by many other spring-flowering subjects, was staged from April 10th to 19th. This was the great Easter Show, for which all Holland was *en fête*. That the Dutch take a keen interest in and are intensely proud of their flowers was evidenced from the crowds which poured in from the outlying districts to Heemstede on Easter Sunday. It appeared as if all the world and his wife were there. One cannot find words to describe the scene in the spacious hall. Reds, whites, pinks, blues, mingled with the dark and light green tints of the foliage to produce such a blend of colour that will not readily be forgotten. Probably the principal feature was the rhododendron in its many varieties, closely followed by the azalea. Of late years a great deal of work has been carried out by Dutch firms, notably Messrs. C. B. van Nes and Messrs. Koster, in the raising of new hardy garden hybrids. That success has attended their efforts is beyond question, judging from the wonderful display presented by those two firms. These Dutch hybrids are both larger and finer in every way than the ordinary type of garden hybrid, and carry large trusses of magnificent blooms of exquisite shades. The owner of any exposed garden will find his requirements excellently catered for if a wise selection of these hybrids be made. In Messrs. C. B. van Nes' exhibit, laid out in the centre of the hall were beds of Unknown Warrior, Mrs. W. H. Gare (Mons. Thiers × Koningen Wilhemina), Armstice Day, Horsham, Britannia, The Countess of Athlone and Van Nes' Sensation (White Pearl × Sir Charles Butler). This latter variety is a magnificent hybrid, carrying large trusses of pale lilac flowers with frilled petals. Many numbered hybrids were also shown which varied from pale pink to deep red tints. Messrs. M. Koster and Sons of Boskoop also staged a large and varied selection, notable varieties in this collection being Raoul Millais with delicate pink blooms 2ins. to 3ins. across, Mrs. Lindsay Smith, a very fine hybrid, almost outdoing Pink Pearl by bearing large white blooms almost 4ins. across; Robert W. Wallace, with characteristic elongated trusses of pale pink flowers; Hugh Wormald, with pink blossoms resembling an amaryllis flower in shape. Azalea Brilliant Red, also staged by this firm, is a variety of great merit from the garden standpoint, and bears abundant blossoms of a shade of orange which assumes a fiery tinge when caught by the rays of the sun.

Azaleas and rhododendrons in variety relieved by flowering laburnums, Wistaria sinensis and double-flowering cherries were exhibited by many other firms. Of special note was the exhibit of Messrs. van Kleef of Boskoop, of Rhododendron Pink Pearl, which formed a perfect sea of colour. Hybrid azaleas, notably crosses of chinensis and mollis, were shown by others, vieing with the rhododendrons for pride of place. Roses, both polyanthus and hybrid teas, contributed in no small measure to the array of colour and bloom; while hydrangeas, staged by Messrs. Jac de Ridder, Aalsmeer, and cyclamens, shown by Messrs. D. Spaargaren supplied the more delicate shades of blues and pinks. The hydrangeas were especially fine and showed the results of careful attention and cultivation, the heads of flowers being 6ins. to 9ins. across. Primulas were also represented by numerous varieties of P. obconica grandiflora, while close by, tulips, rising above the graceful dangling bells of a bed of lily of the valley, supplied a patch of deeper colour. Carnations and orchids, which received considerable attention from Dutch visitors, were in the able hands of Messrs. Stuart Low of London. A very fine exhibit, occupying a large space, was that arranged by Messrs. P. van Nes of Boskoop. The exhibit was in the form of an oval with a raised background of pink, red and white rhododendrons flanked by tall yews, while beds of yellow azaleas and a few brilliant red polyantha roses along with one or two plants of Cytisus præcox, occupied the central part. Messrs. C. G. van Tubergen, in addition to their outside exhibit, presented an excellent display indoors in the form of a walled garden surrounding a rectangular pool. Many uncommon plants were represented and the whole provided rather a pleasing picture. Primulas, of which we noted one species, P. redolens, occupied along with Stylorum crevices in the wall. One of Forrest's finds, Caltha radicans, raised its yellow heads alongside the pool, while varieties of Iris filicifolia, Lilium longiflorum, fritillarias, triteleias, sprekelias, and tritomas also presented their nodding blooms. It was a most interesting little garden in the midst of a sea of colour.

Space does not permit of giving an adequate description of the numerous exhibits, chiefly narcissi, which were to be found in the Annexe. Many firms were represented, including Messrs. Warnaar of Sassenheim and The Welsh Bulb Fields.

In conclusion, the international character of the exhibition may be emphasised. Beds and groups are clearly labelled so that the amateur should have no difficulty in identifying the plants and thus be encouraged to greater effort in the future. In such an exhibition, acquaintance is renewed with all the older well known and time honoured flowers, while a knowledge of new species and varieties is gained. The arrangement and placing of the exhibits have been executed with great skill and meticulous care, and reflect the greatest credit on the committee. During May the exhibition will certainly be at its zenith as the greater part which now shows as tints of green will then be a blaze of colour, and will amply repay the visitor who makes the trip across to Holland.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

SIMPLE GARDENING

WALLFLOWERS.

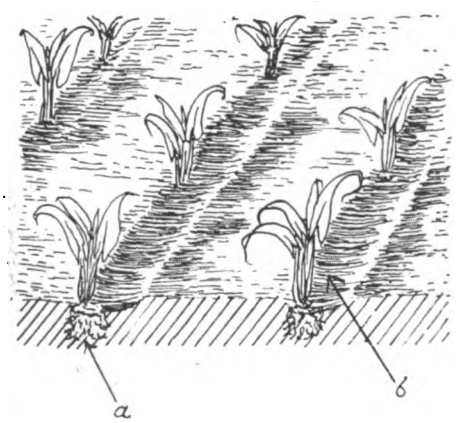
THESE plants will grow in almost all kinds of soil and even in old mortar rubble or a heap of gravel; but the resultant plants are not like those raised and grown on through the various stages with continuous care. Two plants, really well grown, are far more satisfactory than five grown without any detail treatment. We usually grow more plants than are required to fill the given spaces in our borders; they possess a single central stem only, the side ones being too weakly to bear flowers such as they ought. The cultivator should make up his mind as to the number of colours necessary for his purpose and sow seeds accordingly. It is neither necessary nor desirable to sow seeds in boxes or even cold frames—except in the case of a back-yard or very small garden where border room cannot be spared. Prepare a border in an open quarter, not too near a wall or hedge, especially a privet hedge, as the roots of the latter make the soil very poor. Very rich soil I do not advocate, but that of medium good quality and such that can be nicely firmed. Very poor soil should be made richer, as, throughout, the plants should grow steadily and sturdily. Sow the seeds thinly in shallow drills, transplant the resultant seedlings, when about 3ins. high, 6ins. apart in a nursery bed. Keep the soil clean and by October a splendid batch of plants will be available for planting where they are to flower. Every plant should make a flowering specimen 12ins. across at least.

ZONAL PELARGONIUMS FOR WINTER FLOWERING.

Amateur cultivators who possess warm greenhouses or conservatories still retain their affection for these plants and do their best to have a nice batch ready for staging by the month of September. But there are many who are just starting to grow the plants and others who have failed in their attempts. In the first place, the zonal pelargonium is a sappy-stemmed plant, and so we must try to get the wood as hard as possible during the summer months. After mid-June it is not absolutely necessary to have a garden frame for the purpose. We must make a selection of varieties at the present time, if this has not been done in February or March. I strongly recommend cultivators to grow single-flowered as well as double varieties, as the latter suffer from damp more than the singles. If cuttings are to be inserted, root them singly in the smallest pots available—72's—placing them in a frame or on the stage in a greenhouse; if on a shelf in the latter, a little shade will be beneficial at times. Cuttings already rooted should be re-potted as soon as possible. For cuttings, a mixture of leaf-soil, sand and loam in equal proportions; and for the first re-potting, loam two-thirds, leaf-soil one-third, with a small quantity of sand. For subsequent re-pottings a similar compost with the addition of a 5in. potful of bone-meal to a bushel. From mid-June to the end of August place the plants on a bed of ashes in the hottest position in the garden, and remove all flower buds, also stop straggling shoots and feed when the pots are filled with roots.

THE TREATMENT OF ARUM LILIES AFTER FLOWERING.

There are several ways of treating these valuable and useful greenhouse plants after they have finished flowering. A very strong plant will bear five blooms between the month of August and the following Easter; but the majority bear three blooms each. As a general rule we overcrowd the plants in the pots; they increase rapidly, and grading is well worth attention. The present is



a suitable time to grade the plants, placing the strongest on one side, the medium by themselves, and the weakest also, so that there will be three batches of them, the small ones being grown throughout without being subjected to a forcing temperature; they will then gain in strength rapidly. The arum, during its growing season, likes plenty of water both overhead and at the roots, as long as there is not any stagnant water in the pots. Good drainage is essential. Water must not be suddenly and totally withheld; do this gradually. Plant out as shown at *a*, leaving a shallow along the rows as shown at *b*, to retain rain water. If the plants are rested in their pots, place the latter, *c*, on their sides; in due course the leaves will wither as shown at *d*, but they should not be removed before the re-potting or re-starting in the latter part of July. These will bear the earliest flowers, the planted-out ones being lifted in September.

BERRIED SOLANUMS.

The variety most generally grown is Solanum Capsicastrum. The varieties Williams' hybrid and S. Hendersonii are also worth growing, their berries being very fine but, as a rule, not as plentiful as those of the first-named sort. These plants are excellent for furnishing bright colour in the greenhouse during the autumn and early winter months. It is not necessary to have a strong heat, as the plants do very well in the same temperature as zonal pelargoniums. They are not difficult to grow, but to obtain very fine specimens constant care is needed, or the berries will be few in number. At the present time the young plants, raised from cuttings or seeds a few weeks ago, should be in tiny pots on a bed of ashes in a cold frame, whereon mats are placed every night, as frost must be excluded. Fibrous loam and leaf-mould with a small quantity of old rotted manure added will answer as a potting compost throughout their season. About the middle of June the plants should be placed outside in a sunny position, also on a firm bed of ashes. Six-inch pots will be large enough for the final potting. Now all that is necessary to be done till the plants are housed in September is to water and feed them regularly, using clear soot-water twice a week and clear liquid manure also twice a week. On hot days syringe early in the afternoon. Stop any long shoots growing beyond the general contour of the majority.

RE-POTTING AZALEAS.

I am referring now to Indian azaleas, those charming shrubs in pots so much appreciated by owners of greenhouses and conservatories. The plants are often much damaged by bad treatment after the flowers have faded and this chiefly through ignorance as to the proper way to deal with them. They like cool quarters during the hot days of summer and cool conditions may be ensured by placing the plants on a bed of ashes, tiles or slates on the north side of a wall or fence. But before transferring the plants to such quarters it may be advisable to re-pot them. It is unnecessary to do this every year, but every alternate year. I have grown plants nine years without re-potting them, but only as an experiment. The flowers were numerous every year, but smaller, too. Very fibrous loam, from which all loose soil has been sifted, two-thirds, and peat and half-rotted leaf-soil in equal proportions, one-third, will form a suitable compost. Use clean pots and crocks, drain the pots well and firm the new compost. Retain the plants in the glass structure, carefully watering and syringing till the end of May. Then place them outside, continuing the careful watering and syringing till the end of September, by which date the wood will be ripened and new flower buds formed.

GEORGE GARNER.

NOTES FROM CONTRIBUTORS

CALCEOLARIA POLYRRHIZA.

IT is a pity that we have no popular name for this little hardy calceolaria, although by a free translation we might call it the "many-rooted slipperwort." The specific name of polyrrhiza is a great obstacle to many folks, and we might really adopt the title of the "Creeping Calceolaria." It has quite a spreading habit, sending its little roots out in all directions so as to form a mass in the open ground, or in rockwork springing up in all the openings between the stones adjacent to the plant. This is one of the factors in favour of this calceolaria, although not appreciated if we place some other and choice plant too near it without sinking stones deep enough to prevent the calceolaria from ingratiating itself among the roots and growths of the other flowers. But we cannot well afford to do without this, the hardiest of the calceolarias. C. plantaginea and C. Kellyii are not nearly so hardy, although they will thrive in milder gardens, and we can enjoy C. polyrrhiza as it sends up its shining foliage among the rockwork and embellishes its home with its stems bearing branching sprays of yellow flowers, of curious formation and carried on stems varying from 6ins. or 8ins. to even 18ins. in summer. It is a good doer even in a rich border; it will flourish in rockwork. It may also be employed in the crevices of crazy pavement or a retaining wall or in stone steps, and altogether is a charming little plant.—S. ARNOTT. *Dumfries.*

POLYANTHUS FROM SEED.

I HAVE not the least hesitation in stating that the most common garden plants often make a brilliant show and especially among these common plants I would mention the polyanthus. Everyone knows this plant, and I believe that most gardens contain at least a few plants, but not everyone grows them to display their full merits or gives them a chance to exhibit their glorious colours.

The most robust plants are those raised from seed or those which have been divided up during late summer, *i.e.*, after flowering. When the polyanthus is left to grow as it will it becomes a large clump, the flowers decrease in size and the colour loses its brilliancy; when one plant alone, it sends out long shoots which bear large trusses of flowers. Seed should be sown in spring.

If, for some purpose, plants are required true to variety, they must be obtained by breaking up old clumps as indicated above. Plants raised from seed show much variation and cannot be depended upon; but it is possible to have seed of whites, yellows, reds, gold-laced and others. A packet of mixed kinds will give a delightful variety in all shades of selfs and attractive blendings of different shades. I have recently been pleased with seed which I obtained, known as Munstead varieties, mixed. I wish to point out to beginners that the polyanthus is very, very easy to grow; it needs no frame, no shelter and no care beyond transplanting from the open seed-bed when the plants can be handled. —LANARKSHIRE.

HYDRANGEA HORTENSIS.

THIS beautiful shrub, which attains a height of from 3ft. to 5ft., is well worth cultivating, and its compact mass of blooms are very conspicuous among neighbouring flowers. They are largely used for terraces and conservatories, but wherever they stand they are certain to be admired. They are best propagated by cuttings, and these can either be taken direct from a parent plant during August or September, or they can be purchased from any reliable nursery. To take the cuttings successfully, the cut should be made just beneath a joint and be of ripe wood about 6ins. in length. The bottom leaves may be removed and the cuttings inserted in 5in. pots containing a compost of equal parts of leaf-mould and good loam with a fair sprinkling of sharp silver sand. The pots may be stood in a cold frame, as near to the glass as possible, and shaded from the hot sun until the roots begin to form. With this treatment, and a fair watering occasionally, it will not be very long before the cuttings secure a grip. During the winter the frame must be made frost-proof, but when there is a normal temperature a good supply of air may be given. The 5in. pots will be quite large enough for the first year's bloom, and as soon as this has disappeared the plants may be pruned to their base and placed in the frame again for the winter. During March or April it will be necessary to re-pot the plants after their first bloom into pots just large enough to take the roots comfortably. The old soil is well shaken from the roots, and a fresh compost may be prepared consisting of one part rotted cow manure, leaf-mould and sand, and two parts good loam. In June the plants can with advantage be transferred to 8in. pots containing a similar compost and placed in their respective flowering quarters. H. hortensis is a half-hardy plant, and thrives well in the south of England out of doors, but in more northern counties it blooms very successfully in a cool house or conservatory.—J. B. C.

THE FINE LARGE AND COMPACT HEADS OF BLOOM OF HYDRANGEA HORTENSIS.

"EVERLASTING DAISIES": A USEFUL TRIO.

AMONG the flowers which many folk like to call by their common name of Everlasting Daisies, there are three which bear a similarity, viz., rhodanthes, acrocliniums and helichrysums. All may be sown and grown out of doors if desired without being raised under glass, a fact which I think is sometimes lost sight of. When a sowing is made out of doors, the middle of May is soon enough to start, and where the chief object is to grow the flowers for cutting for winter decoration, I find that a May sowing answers. Most people, however, with room available in a greenhouse like to have those very dainty flowers—rhodanthes—earlier, and for this reason sow seed in pans of soil made up of loam, leaf mould and sand, pricking the seedlings off when ready and finally potting twelve or fifteen in a 6in. or 7in. pot. The pink and silvery white forms of rhodanthes—Manglesi and maculata alba — are very charming for indoor decoration, and when in bloom, last a long time. Acrocliniums, being somewhat similar in form, but more hardy, can be sown out of doors where they are wanted to bloom. They delight best in a warm, sunny position and to see them at their best should be sown thinly in groups. Helichrysums are the most robust of them all, and before being planted in their final quarters ought to be pricked out for a time. Three or four feet should be allowed between plants in the borders. All "Everlasting" flowers are best gathered when half opened to allow for expanding in the drying process. —CLAREMONT.

LETTUCES BETWEEN BEETROOTS.

IT is a very excellent plan to arrange that some of the lettuces, at any rate, are between the rows of beetroot. Then, should the summer bring with it a long spell of very dry weather, one can still be sure of fine crisp salad. This is so for a very interesting reason. The leaves of the beet are large and very glossy, and on the surface of the foliage the dew condenses to a considerable extent. In the early morning hours this moisture runs from the tips of the beetroot leaves in a stream. If the ground round the plants is examined before the sun has been up long, it will often be found to have been soaked with water. Naturally, if the lettuce plants are in close proximity to the beetroots they will get all the benefit of this supply of moisture. The hotter and finer the weather the more abundant will be the drenching of dew which they receive. During the exceptional summer of 1911 an old gardener, with whom the writer was acquainted, was the only one who kept up a regular supply of good lettuces. These were all grown between beetroot plants in the manner indicated.—S. LEONARD BASTIN.

GARDEN ECONOMICS

A FRIEND of mine, with a head for figures, told me the other day that he had been working out the expenses of his garden on a costing system and had found that it would have been cheaper for him to buy his potatoes and his vegetables at the local greengrocer and his flowers at a flower shop than to grow them in his garden. I believe that he had arrived at a definite sum saved. Although I had long had a suspicion that under certain conditions a garden was not a paying proposition, yet I scoffed at him as a man with no imagination and the conversation languished.

I have no head for figures and know that I should at once be skating on very thin ice were I to start out on an exposition of garden economics, but it is really a subject that bears investigation.

Gardening is considered a hobby by most owners of gardens whether they work their plot unaided or their domain with the help of a dozen gardeners and it is against human nature to run a hobby as a business venture. In this they are perfectly right, for few people make a living out of their garden and so it remains as a very pleasant bypath of their lives. On the other hand, although the vegetable and the flower garden run hand in hand, yet the one fills our tummies and so helps to satisfy a necessary want, the other gladdens our sight and our general feeling of pleasure and satisfies just as necessary an extravagance. Men who may spend their lives among figures and may have the cleverest business heads in the world, probably never dream of testing the profit and loss account of their gardens. They allot so much money to its upkeep every year and would be hurt and annoyed if anybody told them that as a business proposition their garden was a complete and utter failure.

In many cases there is no escaping the fact that the business side of most gardens is badly neglected and mismanaged. It is nobody's fault or everybody's fault; the owner may know nothing of gardening nor the gardener of business. They both go their own way without that liason which should exist between them, a combining of the two intellects. It is impossible to place a valuation on the enjoyment which flowers give to a household; on the other hand vegetables and fruit have a monetary value of a definite kind, and yet, when economy has to be practised, it is always the flowers which suffer and the allowance for their purchase and cultivation is cut down. I am sure that this is often a mistake. This does not mean that I advocate the policy of more flowers and less vegetables, but rather that the whole question of vegetable cultivation in the garden should be examined, for then there is something tangible on which to work. There are few households which can be supplied throughout the year solely with the produce of their own garden and orchard; likewise, there are few vegetable gardens or orchards which are as productive as they might be. Likes and dislikes in vegetables are strong, so the cook or the housewife should be called into consultation when estimating for the year's supply. Then, as a nation, we do not know how to cook vegetables and we eat too few vegetables cooked and served as separate courses. The planning of the plots devoted to each vegetable may be at fault; which may mean wasted space. The rotation may be wrong and so valuable ground may be lying idle and unproductive for a great portion of the year Odds and ends of ground may not be utilised for catch crops as they might be. It is points like these which I call economics of the garden, or perhaps economies would be a better word.

Flowers also have to take their share of the blame in garden wastage. Every gardener has his successes and his failures. It is perhaps only human that a gardener hates to be beaten and so tries again and again to turn a failure into a success. There may be something in the soil or in the local climatic conditions against him, or it may be lack of experience, or just be mere cussedness, but there surely comes a time when it is as well to bow politely to fate and grow something else which is known to be a success.

No doubt some day some fanatic will try to prove that so many thousands of pounds are wasted every year in British gardens, but until he turns up we may sleep soundly at nights. However cold-blooded it may sound to suggest the commercialising of the most charming hobby that man possesses, it might be as well if everybody examined the economic side of their garden once in a way, just to see if its efficiency could not be improved without taking away from its charm. I should be glad to hear of the experiences of any of my readers who may have a bent for accountancy and have kept thorough garden accounts.

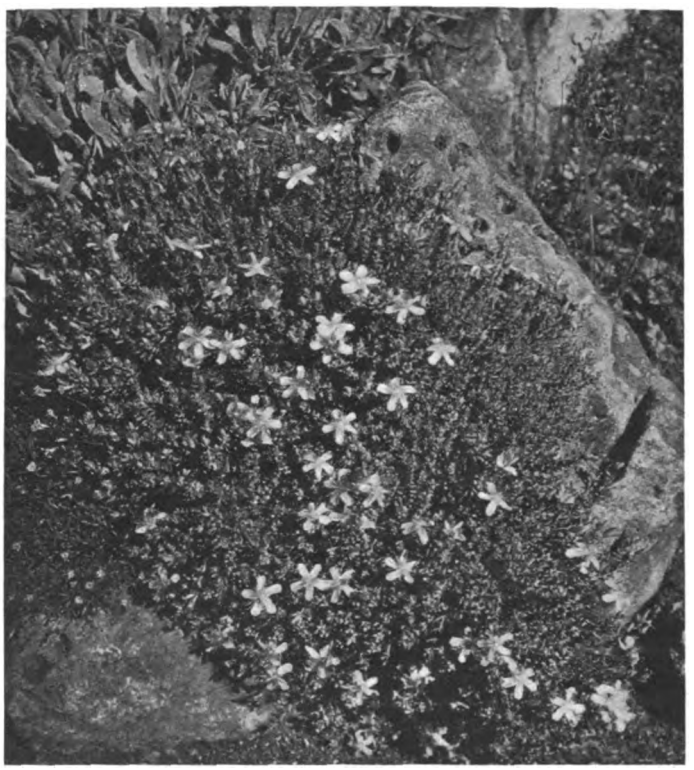
DWARF SHRUBS IN THE ROCK GARDEN—II

BY DR. R. LLOYD PRAEGER.

WE now come to the main body of rock-garden shrubs, namely, those which are neither particularly small nor conspicuously prostrate in habit. Here the number and variety are so great that it would take ten articles instead of one to do them even scant justice. Without a very special knowledge of them it is not possible to make a selection in which any gardener will not miss one or two of his favourites, so I must plead for the reader's indulgence, for I lack that sure touch which appertains only to long experience or to no experience at all. Now, we use these shrubs for rather different purposes in the rock garden. Some may be employed *in addition to* the rock plants, to give shade or to break up a monotonous surface. These should be light-growing things, under or close to which the rock plants will still get enough light for their purposes. At the other end of the series we have small dense shrubs—notably dwarf conifers—which can really be used instead of the rocks themselves, and which have a good deal of the effect of rounded boulders. They are most useful at the back or on the ridge of the rock garden, to form a background or to break up a sky-line. We shall begin with some of the light growers, and work along to the denser groups.

Artemisia tridentata has silvery leaves and a dwarf sparse habit, and is quite effective. Betula nana, prostrate and creeping in its high alpine habitats, makes a light little shrub in our gardens. Several of the coprosmas, such as C. propinqua, are useful in the milder parts of our islands. Coriaria terminalis, which is shrubby only at the root, is very striking with its arching stems bearing a heavy terminal bunch of pellucid orange fruits. The smaller genistas, such as G. nyssana and G. radiata, are wholly commendable, as are the smaller olearias, such as O. Solandri and O. myrsinoides; but some olearias will not do in the colder parts of the country. The cotoneasters, apart from the prostrate species, are mostly too large for the rock garden, but C. rotundifolia is moderate in size and one of the best in leaf and fruit. C. horizontalis, with its flat branches, abundant berries and purple autumn foliage, is a splendid rock garden subject, though it takes up some room. There are a few good light-growing St. John's worts, such as H. balearicum, H. ægypticum, H. empetrifolium, H. Moserianum; and the dwarfer fuchsias, and cytisus such as C. purpureus and the hybrids C. Beanii and C. kewensis, are all airy and free-flowering.



ST. JOHN'S WORTS ARE ATTRACTIVE AMONG THE ROCKS.

Among denser things which form small mounds of foliage there is again a large choice. The rock roses (cistus and helianthemum) are a host in themselves, with a wealth of blossom of every tint but blue, and varying in habit from quite prostrate to 10ft. high. Spiræa bullata is neat and erect, with small dark leaves and red flowers; and S. Anthony Waterer is pleasing, with its variegated foliage and flat panicles of pink bloom. Ribes alpinum var. pumilum aureum makes a very neat little mound of golden foliage, appearing particularly early in spring. Suæda fruticosa, a native of salt marshes, is, on the other hand, very stiffly erect and bright green—rather striking, although its green flowers are minute. Myrsine africana and Ilex crenata are small, evergreen and neat. There are two very curious dwarf forms of Escallonia rubra and Olearia macrodonta respectively, which originated as seedlings in a Donegal garden; both are small, dense and round, and of that bouldery appearance that conforms to a rock garden setting. The smaller forms of that kaleidoscopic "typus polymorphus," Potentilla fruticosa, are quite charming, with leaves green or silvery, and flowers ranging from white to deep gold. But the two most favourite forms, P. Veitchiana and P. Vilmoriniana, are rather large for the rock garden. The allied P. davurica is essentially a rock garden shrub, small, dense and slow-growing: it makes up for its deciduous habit by coming into leaf before winter has departed. There is a group of genistas which make dense hedgehogs of spiny branchlets—G. anglica, G. dalmatica, G. germanica, G. hispanica var. minor (the type makes a grand round mass, but is rather big for anything but a large rock garden): all are very free in blossom. At least one of the shrubby New Zealand senecios, S. laxifolius, is quite hardy, and makes a pleasing grey mass; the smaller, neater S. compactus is preferable, but is not hardy everywhere. Moltkia petræa, a near ally of the lovely lithospermums, resembles them in its flowers of a priceless blue, and makes a tight little bush. The various forms of the familiar rosemary are hard to beat as a background to the rockery, where they may be joined by the dwarf Cydonia Maulei with its early brick-red flowers, of which there are white and deep crimson forms. Corokia Cotoneaster will look well there, too, and for mild districts there are the dwarfer olearias, pittosporums and other distinct-looking New Zealanders. Some of the curious horsetail-like ephedras, relics of a distant age, such as E. Gerardiana or E. americana, look distinct when sprawling in a mass over a rock. There are some dwarf willows that are excellent among the stones; for instance, S. lanata, with its woolly leaves and big catkins. The genus daphne supplies some good upright dwarf shrubs as well as the lovely trailers mentioned earlier; such are D. alpina and D. collina. The protean Euonymus japonicus supplies a whole set of varieties, from creeping to quite erect and dense—often variegated into the bargain. Osmanthus Delavayi is one of the best of all small shrubs, and has recently been very properly praised in THE GARDEN. In flower it is quite delightful. Viburnum Davidii is one of several neat guelder roses. Mention must be made, too, of the many dwarf erect forms of the ivy, Hedera Helix: vars. congesta and minima are among the smallest of these, and many others form fine evergreen clumps.

What are we to say of the veronicas, of which New Zealand supplies such a wealth of shrubby forms? In mild districts a rock garden might be filled with them alone, so great is their range of form, colour and size. It seems almost hopeless to tackle them where space is so limited, and I shall retreat ignobly with the remark that the most pleasing of all are V. Lavaudiana and V. Hulkeana, both of which grow excellently—in some gardens! But almost all are quite easy where frosts are not severe, and they are charming things in flower.

Digitized by Google

Where the soil is free from lime, or peat is obtainable, the door is open for a whole host of lovely dwarf shrubs, mainly belonging to that glorious family the ericaceæ; and here the writer of a discursive article like the present pauses appalled, for the dwarf ericaceæ alone would furnish material for several such articles. Rhododendron would fill a garden by itself, and there are also kalmia, ledum, leucothöe, andromeda, erica, calluna, dabœcia, gaultheria, pernettya, vaccinium and what not. To " save my face " it is presumably necessary at least to mention a few selected species, but even this is unsatisfactory, for one could make a number of such selections, one as good as another. To plunge, then, into the lovely wilderness of rhododendron, a selection for the rock garden (additional to the very dwarf species mentioned in the previous article) might run as follows: Flowers white or nearly so—RR. Colletianum, ferrugineum album, hirsutum album, indicum (white forms), micranthum, moupinense, serpyllifolium. Flowers yellow—RR. Anthopogon, flavidum, indicum vars. Flowers red or purple—RR. amœnum, ciliatum, ferrugineum, glaucum, indicum, × intermedium, linearifolium, lepidotum, ovatum, parvifolium, × præcox, punctatum, Rhodora, setosum, virgatum. Of kalmia there are neat dwarf forms of the white-flowered K. angustifolia; K. glauca has pretty purplish rosy blossoms. Ledum latifolium and L. palustre, and their small cousin Leiophyllum buxifolium, are all commendable and white-flowered, the last having pretty rosy buds. The leucothöes are equally pleasing, the most suitable for the rock garden being L. axillaris and L. Davisiæ. Andromeda polifolia is a thin little shrub with good pink bells. Gaultheria, already referred to, has a number of interesting species, from very small and prostrate to fairly large; but the larger ones have creeping stems which spread rather much for rock garden purposes. The hardy heaths (erica and calluna) are well known and most valuable, and it is not necessary to sing their praises here. St. Dabeoc's heath is especially useful and charming.

This enumeration could be prolonged till the cows come home. I must hurry on, and close with a brief reference to dwarf conifers and the large and indefinite group of sub-shrubs. Many of the conifers, either species or dwarf forms, are particularly pleasing in the rock garden. They are all evergreen, and their shapes often seem to fit the rocks and slopes particularly well. The exigencies of space compel a very small selection almost without description. The following form more or less dense roundish small bushes, matching the boulders themselves: Abies balsamea hudsonica, Picea excelsa conica elegans, P. e. globosa, Cupressus Lawsoniana nana, Thuya occidentalis Ellwangeriana. Juniperus horizontalis (hudsonica) is purplish and prostrate; Picea excelsa repens has a flattish habit, as has Juniperus conferta (= littoralis). Abies pectinata prostrata is a wild, picturesque sprawler. Picea pungens prostrata and Juniperus chinensis prostrata have a good blue colour, and Cupressus obtusa pygmæa is pleasantly coppery. The tiny erect juniper which is usually sold under the incorrect name of Juniperus hibernica compressa makes an absurdly neat little column; its correct name is J. communis compressa. A few other choice things of rock garden dimensions are Picea excelsa pygmæa, Pinus Laricio pygmæa and Cryptomeria japonica spiralis.

POTENTILLA FRUTICOSA MAKES AN EXCELLENT ROCK GARDEN SUBJECT.

GENISTA HISPANICA, WHICH MAKES A GRAND ROUND MASS, AND IS ESPECIALLY SUITED FOR THE LARGE ROCK GARDEN.

Lastly, a word must be added about sub-shrubs—herbs with more or less erect stems which are perennial and eventually become more or less woody. Many of them are very familiar garden plants—southernwood, lavender, cotton-lavender, rue; and they are as useful as dwarf shrubs for giving variety or shelter. The micromerias are valuable, having a neat habit, fragrant foliage, and late blossoming. Alyssum spinosum is quaint—all flowers in spring, all thorns in autumn. The sub-shrub type is characteristic of dry regions, like the basin of the Mediterranean, and often displays the grey, hairy or downy leaves that are common in plants of semi-deserts. To treat this group adequately a separate article would be necessary.

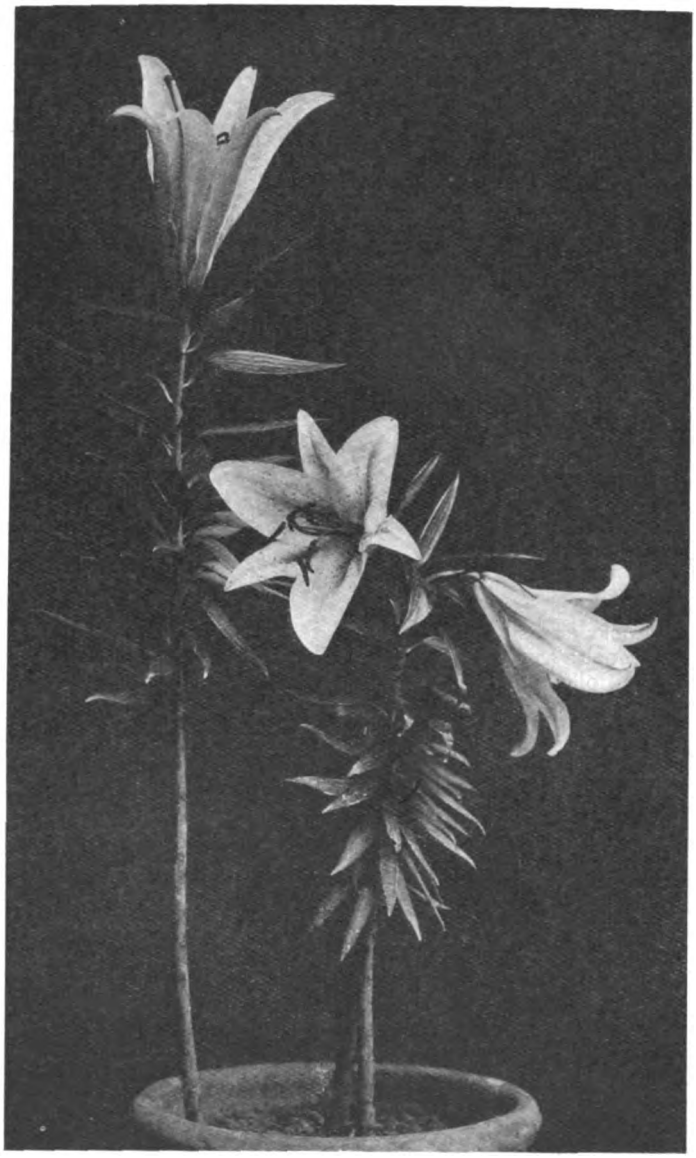
LILIUM ALEXANDRÆ

BY A. GROVE.

A NOTE ON A LILY WHICH SHOULD BE MORE SEEN IN OUR GARDENS. ITS HISTORY AND PECULIARITIES ARE FULL OF INTEREST.

THOUGH of hoary antiquity in the country of its origin, L. Alexandræ is a modern plant to Western nations, and there must be many gardeners who remember its *début* in this country, nearly thirty-two years ago. It made a great stir at the time, and was involved in a piquant air of mystery which must have proved diverting to Japanese botanists and bulb merchants. Curiously enough, two nurserymen were concerned in the introduction of this lily to the public at the Royal Horticultural Society's exhibition at Chiswick on July 11th, 1893, Messrs. J. Veitch and Sons exhibiting it as a species — L. Ukeyuri — and Messrs. Wallace naming it L. Alexandræ, provisionally. At that time no one here seemed to know anything of the history of the plant, or if they did, the knowledge was not divulged. At any rate, in the cloud of doubt as to the identity of the lily, someone conceived the notion that it was a hybrid between L. auratum and L. longiflorum. It has not been possible to discover how the notion originated, but the Yokohama merchants were probably blameless in the matter, since they sent it here under the name by which they knew it — Ukeyuri, literally the lily of Uke-shima (island), one of the Liukiu group of islands south of Japan, and it had no mystery for them. To some extent the notion may have been fostered by J. G. Baker, for in the account of the Chiswick meeting in the *Gardeners' Chronicle* of July 14th, 1893, Baker was reported to have expressed the view that it was a garden hybrid. In the account in THE GARDEN of the same meeting, we read that "L. Alexandræ is supposed to be a cross between L. auratum and L. longiflorum. It is quite distinct, and judging from several plants exhibited, a useful and certainly a handsome lily. The flowers are large, open and of the auratum character. . . ."



A DEFORMED TYPE OF L. AURATUM WITH UPRIGHT FLOWERS RESEMBLING L. ALEXANDRÆ.

Again, "The hybrid character is well depicted in both leaf and stem, the latter partaking of auratum in its formation and colour, while the leaf character partakes of auratum and speciosum . . . and in the firm substance and horizontal aspect of the leaves there would appear a touch of L. longiflorum." Then, in the *Gardeners' Chronicle* for July 22nd, 1893, after closer study of the plant, Baker gave it the *imprimatur* of a formal description, not, however, as a hybrid, but as "obviously a variety of L. japonicum, Thunberg." And there, technically, it has remained since, fitting ill into the place assigned to it, yet still unable to rid itself of the legend which makes it a mongrel.

The air of mystery which surrounded the plant when it was first introduced was deepened some years later by Dr. E. Bonavia, who, on June 25th, 1904, wrote in the *Gardeners' Chronicle* that a bulb of L. Alexandræ which he had flowered in a pot for some years, had split up into two and that while the flower of one was pure white, the petals of the other were a beautiful rose colour with white margins and a crimson stripe along the midrib. Dr. Bonavia suggested that if the lily were a hybrid, one of his bulbs had reverted to the colour of one of the parents. In July of the following year, the doctor wrote again that he had flowered two bulbs of the *red* variety of L. Alexandræ, adding his belief that the white-flowered lily was not of hybrid origin, but was probably an albino form of the red lily. It did not seem to occur to anyone at the time that, following J. G. Baker, Dr. Bonavia was confusing L. Alexandræ with L. japonicum, but that does not make the transformation of the colour of the flower from white to pink (or red, as the doctor called it), any less remarkable. Since Baker's day, there has been ample opportunity to clear up the history of the plant, probe its legendary origin and place it definitely among the natural forms of L. longiflorum. Normally, L. Alexandræ or L. longiflorum var. Alexandræ, as it should be called, holds its flowers in superhorizontal fashion, tending to a semi-erect position, corresponding to the angle at which L. regale usually holds its flowers, but sometimes the flowers assume an upright position. The peculiarity, if we may call it such, is evidently an old one as in "Zôho-Chikin-Shô," a Japanese book published in 1710, which Mr. Takeda showed to the writer in 1911, there is a drawing, obviously of the plant we call L. Alexandræ; the Japanese, too, call the plant the Upright Lily, and when he published this lily as L. noblissimum in the Tokyo Botanical Magazine in 1914, Mr. Makino reproduced this old illustration. All this was a little confusing till it was realised that the vertical position was no more normal than in the case of L. auratum, in which, and in typical L. longiflorum as well, the upright position occurs now and then, usually in uni-flowered specimens.

Many years ago, in conversation with the writer, Mr. Alfred Unger of Yokohama, who was well versed in all that pertains to Japanese lilies, repudiated the idea that L. Alexandræ was of hybrid origin. It was found, he said, on Uke-shima and other of the Liukiu islands, and though not exported till 1893, had been known to the Japanese for centuries. The

Digitized by Google

flower is shorter than in typical L. longiflorum, and more widely open; the petals are paper-white and of substance, without blemish or markings, slightly reflexed at the tips; the inside of the trumpet is tinged with the green of the young apple leaf. The fragrant flower is of refined character, recalling in a way a much enlarged edition of that of the white rhododendron Griffithianum. A peculiarity of the leaves is the claw or petiole by which they are attached to the stem. The plant figures regularly as L. Ukeyuri in the Japanese bulb catalogues, and its cultivation is not difficult in those parts of this country where it can be prevented from spearing through the ground early in the year.

BULB NOTES

HYACINTHS AND WOMEN'S INSTITUTES.

MEMBERS like to feel they are doing something. Local branches round about where I live went in for growing the old-fashioned Dutch hyacinths last winter, and had exhibitions of the results at one of their usual monthly meetings. I was the judge on one occasion and was very impressed with the keenness of the members. I mention this in case the idea is local rather than general. It is an idea for any branch that has not tried it. No bulbs are as easy to manage in pots as Dutch hyacinths. They are a cottager's bulb every bit as much as a pelargonium is a cottager's plant. In case this note puts a match to a smouldering fire, I am going to suggest half a dozen varieties which are suitable and easy to manage. They are L'Innocence, white; Menelik, dark blue; Grand Maître, medium blue; Perle Brilliant, pale blue; General Pelissier, red; and Lady Derby, rosy-pink. In case a pale pink is preferred to such a very dark blue as Menelik, I would suggest General de Wet. I do not think it is necessary to buy first-sized bulbs. If good second-sized bulbs are obtained from a reliable source I find they are quite good enough for ordinary people, and just as much pleasure and fun can be got out of them. If it is intended to have a little competitive exhibition in the spring, may I suggest that one bulb only in a pot should be the strict rule. I know what a job it is to judge when it is otherwise. When, that is, from three to five bulbs are grown in one receptacle, and these are not all the same variety.

EARLY PERFECTION POETAZ.

I must again refer to this splendid variety. I saw a little exhibit of it at the first special show in March last at the Big International Exhibition at Heemstede. It looked well, but it was really past its best, which, of course, is an eloquent and silent testimony to its earliness. One of the owners of the stock gave me a postcard picture of it growing in their bulb fields. There was a very big mass of it, but the world is big too, and there may not be enough to go round. I hope, however, there will be some in British catalogues this next autumn. It has a white shapely perianth with a yellow cup and from my own experience I can say it is free-flowering and *very easy* to get into bloom about mid-January.

CROCUS "QUEEN OF THE BLUES."

Seekers after novelty and size will find this a real treasure. I have heard it said that "Finality is the only heresy." However this may be in a theological sort of way, it is certainly true horticulturally. Pick out the very largest variety you know in 1925, in a few years time it will have its nose put out of joint and it will have to take a lower place. Queen of the Blues, which I think is a 1925 novelty, will do to go on with for a while. There may be varieties with larger blooms, but I have not seen them; nor in the course of conversations have I come across anyone who has. If, however, size were its only recommendation, it would not be mentioned here. It is of a very charming shade of what in crocusdom is called blue—a sweet-toned, many shaded mauve in the language of the world. Of its early-flowering habit there is no doubt. Its value in this respect must depend upon the weather—according to mild, sunny spells synchronising with the blooming time of King of the Blues or not.

HYACINTHS AT THE INTERNATIONAL.

The fine display of hyacinths by the community of Overveen at the first of the series of special shows on March 12th was at once of historical and botanical interest and of present day utility. The historically minded could feast their eyes on such ancients as the quaint double yellow Goudbeurs (Purse of Gold); or the rosy Hofdyk, with each of its bells tipped with a little green, which gave it a decidedly piquant look which to me was very pleasing; or, again, the pale pinky buff Tamerlan, which is a pale pink toned primrose, a little washy-looking, perhaps. These they could compare with some of the very latest out, like the fine distinct yellow, Prince Hendrick, with its narrow segmented blooms; or the exquisite pale blue toned mauve Pride of Holland, or Daybreak, a striking rosy apricot, not a hundred degrees removed in colour from my old favourite Orange Boven; or, if one went to the long corridor, where a collection of seedlings was staged, there were many there which were still a long way off being in commerce. I had the opportunity of discussing them with one of the big hyacinth men of Holland and his comments on my "spots" made it abundantly clear that present day vendors are going for tight spikes and pale colours. I singled out a big-flowered rich deep Oxford blue here and there relieved with white shading as my choice. My mentor said, "no good, too dark," but the owner of the group said that most people had gone for it. There were many choice varieties, among others Spring Glory (white), Competitor (large rose after La Victoire), Salmon Queen (salmon pink), and Louis Paster (deep blue).

Botanically, it was interesting to see how some varieties had sported. The hyacinth in this respect may be compared with the chrysanthemum. Both are old hands at the game. Just as Marie Masse has given us several distinct colour variations, so has the well known King of the Blues. Some of these were represented in the big Overveen collection. I noticed Codra, almost the latest effort of the old "King" (in which it has taken on a double form), Ivanhoe, Purple King, Queen of the Lilacs and King of the Violets. Grand Maître (a blue), is also a big sport. Two lovely ones in the group were General de Wet (pink) and Pride of Holland (pale mauve). I am told that the explanation of the sporting in the two families is not the same. In the hyacinth it may have to do with the dropping out or the addition of one or more factors, while in the chrysanthemum it is a bud from a different layer of cells from the ordinary which suddenly takes it into its head to assert itself. I wish some one would explain this sporting properly and popularly. Thanks to the Baconian assiduity of our modern Bateson much has been found out, but an interpreter seems necessary to put his knowledge in such a way that it may be easier for the hypothetical man-in-the-street to digest. Will some one tell us about this sporting?

TULIPA OCULIS-SOLIS.

As I write, on the last day of March, my clump of Tulipa Kaufmanniana is past its best and my clump of oculis-solis is about half out. It gives a welcome bit of bright colour at this time of the year and under favourable conditions can look after itself. Two years ago I saw it in Messrs. Veitch's nursery at Exeter, where it had become acclimatised and had sown itself in several places. All anyone has to do if they feel doubtful about its behaviour if left in the ground for the summer, is to lift it at the same time as one lifts other tulips and re-plant it in early November. The petals have a pale look on the exterior as if some thin, light-coloured wash had been painted over them. The interior is a crimson or carmine (for the shade of red varies), with a large well defined black base and a symmetrical edging of yellow more or less almond shaped on each petal. Præcox, which is somewhat similar in its general appearance, is said by botanists to be a form of oculis-solis, but may be distinguished by its having the exterior of the petals a good solid, dull carmine and the basal blotch not such a dead black and with a blurred yellow edging. It is, too, rather the earlier to bloom. One or the other of the above-mentioned species are very welcome additions to a spring flower garden, as they lend a distinct tone of valuable bright colours which are so rarely present during these early weeks.

PLANT HOLIDAYS—I

BY H. STUART THOMSON

NO ONE KNOWS WHERE THE ALPINE FLORA CAN BE SEEN AT ITS BEST SO WELL AS MR. THOMSON, AND IN THIS AND THE NEXT ISSUE HE DESCRIBES VARIOUS CENTRES WHERE A PEACEFUL HOLIDAY MAY BE SPENT OUT OF THE WAY OF THE ORDINARY TOURIST TRAFFIC.

ASKED to write an article on some of the best districts for plants in the Alps and Pyrenees, I find it difficult to know where to begin, or end. Moreover, as the only parts of the Pyrenees I ever visited are in the Eastern Pyrenees: Vernet les Bains, Mont Louis and Cambras d'Aze, and thence down the valley of the Aude to Carcainères and through the Defile of St. George to Quillon, very little could profitably be said which has not been published in these columns by botanists and collectors who have more recent knowledge.

Let us therefore pass to the Alps, where the hotels are better, even the smallest of them, the flowers at least as beautiful, the country more accessible, and where reliable and intelligent guides and porters are to be found in almost every village, particularly in the Swiss Alps.

But before reaching the Alps proper, there is in the extreme south, at the back of Marseilles and Toulon, the wonderfully picturesque limestone Chain of Sainte-Baume, which is a locality very rich in southern plants and scarce sub-alpines and hardly known to Englishmen. It may best be approached by diligence from the market town of Aubagne, just east of Marseilles, to the village of Gémenos at the foot of the mountains. June is the best month to visit this enchanting country, and fair accommodation may be obtained in several small French hotels on the plateau (Plan d'Aups), and there is an older and larger hôtelerie at the farther or east end of the plain. Plan d'Aups is at a slightly lower elevation than the Col de Bertagne (3,oooft.), which one passes in walking up the extremely interesting slopes from Gémenos. The range of mountains attains about 4,oooft. above the sea; and on some of the rocks on the north side several saxifrages, Silene Saxifraga, Daphne alpina and other alpines intermingle with the more southern species.

Just above Gémenos there is a sawmill by the roadway, and from this mill is a shady path through a remarkable grove of Judas trees (Cercis Siliquastrum) and Holm oak (Q. Ilex). The Aleppo pines, which are at first dominant, pass into Garigne, the Provençal name for the shrub association of limestone hillsides. Amid the pines the following Mediterranean plants are frequent: Rhus Cotinus, Pistacia Terebinthus, Coronilla juncea, spartium, Cistus albidus, Teucrium Polium, the queer little blue aphyllanthes and the porcelain blue Linum narbonense. Higher up are Lathyrus latifolius, Astragalus monspeliensis, coris, Stipa penanta, Leuzea conifera, Cephalanthera rubra, Pyrethrum corymbosum, Antirrhinum latifolium. At just above 2,oooft. the handsome Vicia onobrychioides, Helianthemum polifolium, genistas and orobanches, Bartsia latifolia, Allium roseum, Limodorum, Catananche cœrulea, Epipactis atrorubens, Teucrium aureum, Arenaria capitata and Linum salsoloides are among the plants to be seen in greater or less quantity.

On a grassy plateau before arriving at the Col, the deep blue shrubby Lithospermum fruticosum, very similar to L. prostratum, will be noticed. The vegetation of the Pass is especially noteworthy for small prickly undershrubs and greyish plants, simulating the broken limestone upon which they grow. When at Sainte-Baume at the end of June, 1913, a band close to Plan d'Aups was covered with Lathyrus canescens, one of the loveliest peas, with large pale purple flowers.

In the pine woods of the plateau are other interesting plants, and a greater variety can be seen in the great Forêt domainale de Ste. Baume, said to be one of the most interesting mixed forests in Europe. Tansley refers to it in his "Forests of Provence" in the *Gardeners' Chronicle*, 1912. The undergrowth is similar to that of a limestone wood in Switzerland, and comprises Lithospermum purpureo-cœruleum, Ruscus aculeatus, A. Hepatica, Coronilla Emerus, Lilium Martagon, etc. Among shady rocks at about 2,5ooft. the handsome Saxifraga lantoscana reaches its western limit in Europe. Another rare plant, Senecio Gerardii, only known in France and much like a green-leaved S. Doronicum, may be looked for on the ridge leading to the Croix aux Béguines, where the flora is very rich; and the rocks of the Col du Pillon are clothed with the rare silvery Paronychia capitata var. Kapella.

The Sainte-Baume range forms an attractive and quite unique place for the flower lover to visit on his return from a late spring sojourn on the French Riviera, or if he finds himself in May or June at Marseilles or Toulon with a few days to spare. Further information can be found in a paper by the writer in the *Gardeners' Chronicle*, 1915, page 49, *et seq.*, or in Dr. Mader's "Le Massif de la Sainte-Baume," in Malpighia, Vol. XX, 1906.

The Maritime Alps have the advantage of being accessible to the plant collector perhaps a month earlier in summer and later in autumn than the Swiss Alps. The alpine, or Argentera, district west of the Col d'Altaire, is separated from the lower Ligurian mountains, which are more Apennine in character, by the famous Col di Tenda, over which the great road runs from Nice to Cuneo and Turin. I believe the railway is now continued through the Col di Tenda southwards to S. Dalmazzo and Ventimiglia.

Among the Ligurian hill villages above Bordighera a week or two in June might advantageously be spent at Pigna (Hôtel de Paris), which is prettily situated among olives and sweet chestnuts, 1,oooft. above the sea. Bajardo is another village a little higher. The chestnuts extend to about 3,oooft. on Monte Toraggio, where they give place to pines and larches; and the olive reaches about 1,8ooft. in this district. Visitors should take with them the late C. Bicknell's useful little "Flora of San Remo and Bordighera," 1896. Two interesting ferns Cheilanthes odora and Pteris cretica, are well established near Pigna; and the three handsome lilies, LL. croceum, pomponium and Martagon, adorn some of the grassy slopes. L. pomponium grows up to 6,oooft. on some of the mountains, as on Monte Wraggio, a beautifully proportioned rugged mass, whose upper slopes in June, before the pastures are mown, afford a host of brilliant flowers. These alps, extending to 6,oooft. on Toraggio, are bedecked with gentians, anemones, Orchis globosa, ustulata and sambucina, Cerinthe minor, Narcissus poeticus, Pedicularis comosa and P. gyroflexa. There are some big patches of peony on the highest slopes, and on the rocks are various saxifrages, including the endemic S. cochlearis and the even more beautiful S. lingulata.

San Dalmazzo di Tenda, 2,284ft., is a village with a good Italian hotel, beautifully situated at the junction of two lateral valleys with the main valley, which I can strongly recommend for a longish stay in June or July. I can remember nothing against it at midsummer except the flies, but against such pests could be put the charm of the fire flies in the evening. San Dalmazzo wants the pen of a Farrer or the poetic genius of a Correvon to do it justice; but I think our late friend R. Farrer knew St. Martin Vésubie (formerly called St. Martin Lantosque), better, and he certainly wrote more about it in "Among the Hills." San Dalmazzo has greater variety however. A step across the road leads into the shade of an ancient chestnut grove in which are brilliant campanulas, Astrantia major, Epipactis atrorubens and latifolia hybridising, Thalictrum minus and Cephalanthera rubra 2ft. high. On the rocks by the roadside are pinks and helianthemums in variety, Lilium croceum and the white-rayed Orlaya grandiflora. Across the river are limestone cliffs and screes where many good things are to be found, including Micromeria piperella, Potentilla saxifraga, Asperula hexaphylla and Thymelæca dioica. Butterflies of many kinds are also numerous.

Among the rocks and thickets above the road to Briga, a delightful village and suitable place to get tea on a hot afternoon, the handsome spikes of Delphinium fissum may be seen if well searched for, and the curious Telephium Imperati, which botanists were long doubtful how to classify, grows on the roadside wall and among broken limestone. Here also are Inula montana, Vicia onobrychioides and the two trigonellas, TT. monspeliaca and gladiata.

THE SELECTION OF A LAWN MOWER

WITH NOTES ON ITS UPKEEP

IN initial outlay the mowing machine is perhaps the most expensive single item in the whole range of garden appliances, and there can be no doubt that the selection of a reliable machine is a matter which requires careful consideration. "Penny wise and pound foolish" is an old, but very true, saying, and the small saving which is often effected by the careless purchase of a cheap machine of doubtful origin usually proves to be very false economy. A bargain (?) of this nature is seldom, if ever, satisfactory, and the money saved in original expenditure is generally quickly swallowed up by bills for repairs and replacements. Nor does the question of expense entirely disappear with the purchase of the machine. Even though one buys the finest type of machine obtainable, a lot will depend on the manner in which it is treated if the cost of upkeep is to be kept low and the standard of efficiency high. More damage can, undoubtedly, be done in a few weeks by faulty adjustments, careless usage, slovenly inattention, amateur tinkering, etc., than by many seasons of fair and honest work. Cleaning after use is an operation which takes but a very few minutes, and should never be omitted. One cannot expect good service or light running from a machine when the bearings and gears are clogged with mowings and dirt, or the cutting knives dulled and rusted from constant contact with wet grass. In spite of this, many people are content to keep their machine on about the same level as their dustbin. Cleaning, if done regularly, is a simple task, but it nevertheless adds 100 per cent. to the efficiency of the machine when in use. An old spoke brush is one of the handiest things for removing most of the dirt and clippings, while a disused tooth brush, or even a thin piece of wood, will serve to reach the more inaccessible parts of the mechanism. After cleaning, wipe all parts, particularly the knives, with an oily rag and give the bearings a slight lubrication with a good oil. Use an oil which is neither too heavy nor too light in substance and, above all, use it regularly. The main object of oil is to lubricate the bearings and keep them from running hot and dry. It is not intended to be used as a bath, and to scatter it lavishly over all parts of the machine will be found an expensive procedure. The result of this can often be seen in filthy blotches of grease dropped here and there on the grass when the machine is in use. Superfluous grease also acts as a magnet to dust, a fact which will be quickly realised when cleaning takes place. Use oil sparingly but regularly when the work is actually being done, and see that what you do use goes in the right place. Every hour is not too often to use it when the machine is running, and the beneficial effect will be felt by those in charge.

Accurate adjustment is necessary for good work, and the short time spent in obtaining this will be found worth while. It is essential that the cutting edge of the knives should rotate in perfect alignment with the shear blade, otherwise the lawn will assume a ribbed effect after mowing. In most of the modern types simplicity of adjustment is an important feature, so that this problem should not present many difficulties to the majority of people. Prior to and during mowing operations a sharp lookout should be kept for stray stones and other foreign matter, which, however careful one may be, often find a resting place on the grass. They should be immediately removed or serious damage may be done to the blades and mechanism if they come in the path of the machine when working.

Many methods have been advocated for sharpening dull blades, but in practically all cases they can only be described as unsatisfactory. This is a job which is beyond the power of the average handyman, who, as a rule, is capable of making more noise with a file or grindstone than he is of performing this delicate operation correctly. It is perfectly correct to say that it is no more sensible to attempt the sharpening of these blades with a file than it would be to try setting one's favourite razor by the same method. To grind a rotary cutter accurately demands considerable skill and the use of an elaborate plant. This can seldom be obtained locally, and in most cases it will be wiser to return the mower periodically to the original makers, who can always be depended upon to make a thorough overhaul in a skilful manner.

The many types of horse, hand or motor-power machines on the market to-day offer a very wide field from which to choose, and the final selection will, of course, be governed by the size and nature of the lawns on which the mower is to be used. For those who already possess a trustworthy machine but who feel that hand mowing is too tedious and fatiguing, there is the choice of an "M. P." or a "Rendle" motor attachment, either of which can be fixed very easily to most standard makes of mowing machine or roller. Each of these consists of an independent power unit, the working of which is so simple that anyone can learn to attach or drive it in a few moments. All physical labour is abolished and the operator sits and guides the machine as it runs. A very large area can be covered in a short space of time, and the running charges of each are exceptionally low. The number of hand and pony machines is legion, and space will not allow of details being given regarding the faults or virtues of each one. Green's "Silens Messor" or "New Royal," Ransome's "Automaton" or "Lion," and Shank's "Caledonia" or "Talisman" are all very excellent types which are too well known to need description. Furthermore, they are made by firms who have specialised in the manufacture of mowing machines of all types. Others worthy of mention, whose makers are of perhaps more recent introduction to the gardening world, are the "J. P." and the "Qualcast Major." The former can only be described as a *model de luxe*, for all parts run on ball bearings, while the gears, etc., are encased in dustproof covers and run in oil. The roller is in three sections, which form a differential action when the machine is turning, thus preventing the tearing up of the turf. Both front rollers and rotary cutters are governed by two handwheels, which render adjustment a very simple matter. The "Qualcast" is not built on quite such elegant lines but is designed for good hard work, and

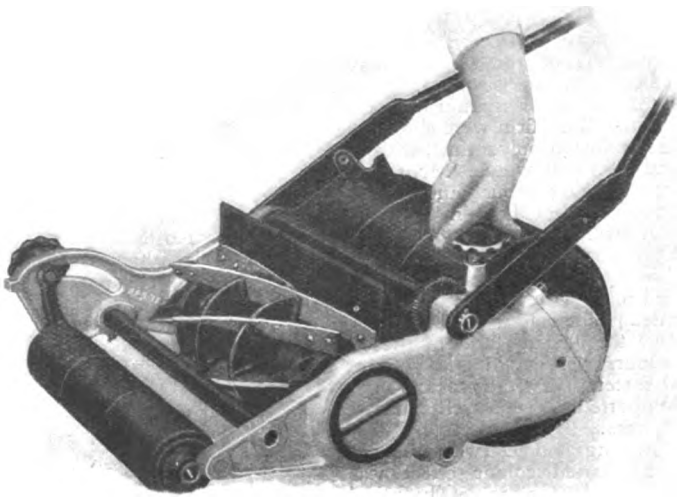
all parts are guaranteed. All of the machines mentioned are British made and, quite apart from this excellent guarantee of good construction, this reduces to a minimum the trouble and expense of obtaining spare parts when required.

For cutting large areas the motor mower is gradually displacing the horse, pony and larger types of hand machine and, while at first glance the high prices charged for up-to-date models seem to render them prohibitive to all but the very wealthy, this is not the case. The additional outlay is usually saved during the first season by their economical working. With most types it is possible for one man or boy to mow an area of 1,000 sq. yds. in from fifteen to twenty minutes at the trifling approximate cost of 2d. for fuel. In this section we again find the names of Green's, Ransomes and Shanks prominent, for these firms, bringing their vast experience to bear upon the subject, have produced a very extensive range of motor machines for all purposes, ranging from 1½ h.p. to 4¼ h.p. The lighter types of from 16in. to 20in. cut are eminently suitable for use on small sports grounds and private gardens, while the larger and heavier machines are more adapted for use on larger estates and parks. The choice is by no means limited, for the following are all very excellent machines:

The "Atco" is a product of Birmingham. An important feature of this machine is the fact that provision has been made for fitting a special turf cultivator, to be used in conjunction when mowing for the purpose of aerating the grass.

The "Governor," made at Wolverhampton, has many outstanding features. One of the main points is the cross serrations on the land roller, which, as shown in the illustration on opposite page, is a three unit item. This undoubtedly provides a great safeguard against skidding, slipping or otherwise tearing the turf when turning or working on sloping ground.

The "Dennis," manufactured by the famous firm of motor lorry and fire engine fame, hails from Guildford. It is, from all points of view, a machine which can be relied upon to give every satisfaction.



THE HANDWHEEL ADJUSTMENTS IN THE "J. P." MOWER.

In most cases the motor controls are conveniently fixed to the handles and a clutch fitted to throw the rotary cutter out of gear when the machine is wanted for rolling only. A trailing seat can be purchased for use with most makes if this is thought necessary. J. C.

ALPINE PLANTS AT VINCENT SQUARE

As befits the season, alpine plants were an important feature of the Royal Horticultural Society's Show at Vincent Square, Westminster, on April 21st and 22nd, and a large and varied collection was shown either as pot plants or, more naturally, set in groups and drifts in small rock gardens.

Although the exhibit was of pot plants and pans, the fact that these receptacles were set among small pieces of rock gave the large collection from the gardens of the Hon. Vicary Gibbs, Aldenham House, Elstree, an appropriate setting. The beauty of the exhibit was also enhanced by the mounds of deciduous azaleas which pleasantly relieved the general line of the alpines. Azalea Yodogawa Double Mauve is an attractive shrub, about 2ft. high and well furnished with relatively large flowers; while the batches of Azalea Amœna varieties provided agreeable colouring. The central alpine was a large pan of Primula denticulata. Other attractive examples of the same genus were P. chionantha, of fairly robust habit and nearly white flowers; the yellow P. Forrestii and, P. rosea grandiflora, a valuable variety of a beautiful species. The saxifrages included Aldenham Pink, Dr. Ramsey and Letchworth Beauty. There were various anemones, the bright single red Bellis sylvestris, a delightful form of Androsace carnea Laggeri and a most attractive little bush of Daphne neapolitana. This fine exhibit received a gold medal.

Next in point of interest was a collection from Mr. Clarence Elliott. Although we did not care for its concrete bordering, we were charmed with the breadths of lovely white-eyed blue flowers of Gentiana verna, and, realising the use of the receptacle, we forgave its ugliness. At the other end there were some plants of Viola Bluestone, whose name is quite descriptive of the uncommon shade of dark blue colouring. Petrocallis pyrenaica was a desirable plant, though the principal feature was the auriculas, which were most fascinating. Mrs. Wilson, pubescens Ladybird, Zuleika Dobson, were all of great decorative value. Among the saxifrages there was an admirable pan of Griesbachii, which in its uncommon habit and colour of the flower stems was only approached by the pans of S. Gusmusii, shown by Messrs. R. Tucker and Son, who also had two fairly uncommon daphnes in D. rupestris grandiflora and D. Cneorum alba.

Armeria cæspitosa is a sturdy little thrift which blooms very freely. Among other growers Messrs. W. H. Rogers showed it and they also had a good batch of the dwarf blue-flowered Iris azurea. The dwarf irises were well shown by Messrs. Barr and Sons, whose plants, only a few inches high, bore quite large flowers of considerable beauty. Iris obliensis Socrates, I. pumila cœrulea, I. elegans and I. lutea maculata are the names of only a few of them.

The daisy-like Helichrysum bellidioides which was shown by Messrs. Carter Page and Co. is a pretty little plant of spreading habit. They also had the charming little Cyclamen repandrum and Primula farinosa, which seemed almost like a smaller and hardy variety of P. malacoides.

A couple of perfect little bushes of the delightful Daphne Cneorum were included in his exhibit by Mr. F. G. Wood, who also staged the dark blue flowers of Muscari paradoxa and the very quaint Fritillaria pyrenaica. The most uncommon snake's-head lily in the Show was F. latifolia, of almost evil yet fascinating appearance. This and the greenish-flowered F. acmopetala were brought from the noted Colesbourne Gardens by Mr. W. H. Walters, with other rare and interesting plants. Euphorbia sikkimense is very attractive in the vivid colouring of the stems and on the midribs of the leaves. Morea spathacea is much like a slender, graceful iris. Although not hardy, the long tubular flowers of Cantua buxifolia were most beautiful. This is a cool greenhouse climber which will thrive in a northern aspect. Many years ago some gardeners grew it in large pots trained as umbrella-shaped specimens, a method which showed off the uncommon flowers admirably.

Besides a great many rhododendrons of the type associated with the warmer parts of the country, Mr. G. Reuthe brought, in a pan, several plants of Rhododendron kamtschaticum. This is of exceedingly uncommon appearance. The almost minute, deciduous bushes are of delicate appearance, and they throw up stems only a couple of inches or so high, crowned with relatively very large saucer-shaped flowers of bright rosy purple colour. Sanguinaria canadensis is an elegant white blossom of windflower-like appearance. Calypso borealis was another attractive plant in the same exhibit, which also contained a brilliant mass of Anemone fulgens.

Vivid colour in dwarf plants was also provided by the masses of a red daisy well named Ball of Fire and shown by Messrs. B. Ladhams, Limited. Alice, delicate pink; and Shirley, a deep pink, are good companion sorts.

The dwarfest of brambles was to be seen in Rubus arcticus on Mr. M. Prichard's stand. It is only a couple of inches or so high and crowned with round rosy flowers: a drift in the rock garden would be exceedingly effective. He also brought a fine batch of the lovely blue Gentiana acaulis and Æthionema Warley.

Ranunculus amplexicaule, a graceful white buttercup, which is relieved by the yellow centres, was shown by Messrs. Waterer, Sons and Crisp, who also had an attractive variety of Fritillaria Meleagris, Shortias, Aubrietia rosea splendens, and Saxifraga bathoniensis.

Messrs. Blackmore and Langdon were exhibiting a fine strain of polyanthus. The sturdy plants carried a mass of bloom, some flowers measuring nearly 1¼ins. across. There were yellows, whites and velvety

Digitized by Google

crimsons, and a flame-coloured polyanthus streaked with yellow was very attractive. Messrs. John and A. H. Crook had a varied collection of polyanthus. The substance and shape of the flowers were noticeable rather than the size. Large-sized flowers are not always a meritorious feature in polyanthus. This firm were showing a very good deep crimson polyanthus, with a well defined and clear yellow eye. Mr. G. A. Miller also was showing robust and well grown polyanthus of a good strain.

A striking effect was produced by Messrs. Sutton and Sons' excellent exhibit of May-flowering and Darwin tulips. A large oval bed filled with many varieties of both classes in exquisite colouring showed to great advantage the elegant form of these tulips. The colours were vivid and yet not harsh, and the stems of nearly 24ins. long supported large, well shaped flowers. By combining May-flowering and Darwin tulips a more varied colour effect was produced, for some beautiful yellow and bronzy orange May-flowering varieties, such as Bouton d'Or, Inglescombe Yellow and Bronze Queen, were included, whereas if only true Darwin tulips had been used there would have been no yellows. King Harold was a fine deep crimson Darwin; and Farncombe Sanders, a rosy red, was about the longest-stemmed variety exhibited. With the exception of Prince of Wales and Rev. Ewbank, all the varieties exhibited were exceedingly beautiful and formed a wealth of colour. Among them were Afterglow, a charming shaded apricot; Le Reve, a pinkish shot-silk colour; City of Haarlem, a crimson variety with a white edge; and three May-flowering tulips—Bacchus, a deep wine colour; Grenadier, a brilliant scarlet; and Panorama, an unusual bronzy red. King George V, a lovely cherry red; Zomerschon, a white streaked with cerise; Princess Elizabeth, Orient and Prince of Orange were a few more of the best varieties.

The reason that only a few roses were exhibited at the Hall this week and that some of these were not in first-class condition, is that the majority of rose growers are saving their best for the National Rose Society's Show on April 24th. One rose which attracted particular attention is a comparatively new variety, raised by Mr. Walter Stevens and exhibited by Messrs. Stuart Low and Co. This variety, called Roselandia, is a sport from Golden Ophelia, but has a larger flower, the colour is deeper and the stems are stiffer and more upright. The pointed bud is deeper yellow at the base. It will probably be a very popular variety in the near future. Messrs. Stuart Low and Co. were also showing healthy and fine specimens of such varieties as Padre, Sovereign, Phœbe and Mrs. Beatty. Messrs. Benjamin R. Cant and Sons were exhibiting Lady Wakefield, an excellent rose of a salmon-pink shade and sweetly scented, but its fragrance did not rival that of its neighbour, the well known variety Covent Garden.

Dwarf polyantha roses in pots, grown as bushes or standards, are very decorative and are profuse bloomers. A good exhibit of this type of rose was shown by Messrs. Cutbush and Sons, who included in their collection such varieties as Edith Cavell, Orange King, Salmon Queen, Orleans Rose and Tausendschön. Orange King is quite a break in colour, the pinkish orange flowers are small and very dainty. Salmon Queen is a paler shade; and Orleans Rose is of a similar colour but darker, and so lacks that softness in tint which adds to the beauty of Orange King. Mr. J. H. Pemberton was also exhibiting dwarf polyantha roses. One of the best among his roses was Rudolf Khuis, a red form of Ellen Poulsen; the flowers seem to bloom quite as freely as Ellen Poulsen and at the same time are a little larger. Koster's Orleans, a brilliant red; Eblouissant, another red; Echo, a delicate flesh pink with crinkled petals; and Juliana, a coral pink, were all admired.

There was a marked improvement in the carnation exhibits. In general condition and in colour and size, the blooms shown were much superior to those exhibited at Vincent Square during the past few weeks. The three well known firms of Messrs. Allwood Brothers, Messrs. C. Engelmann and Messrs. Stuart Low had good collections of well grown carnations. Topsy, Janet, Lady Hindlip, Sir Philip Sassoon, Edward Allwood, Shot Silk and Michael Stroop were some of the varieties exhibited.

THE PERFECTLY FORMED YELLOW BLOOMS OF ROSE ROSELANDIA.

Among the other exhibits were:

Anemones.—Messrs. R. Gill and Sons, and Reamsbottom and Co.

Echiums.—Messrs. Sutton and Sons.

Fritillaria.—Mr. W. H. Walters.

Fruit.—Messrs. Bunyard and Co., and Westmacott and Co., Limited.

Greenhouse Plants.—Messrs. L. R. Russell and Co.

Hardy Plants.—Mr. B. Ladham.

Hydrangeas.—Messrs. G. and C. Cuthbert.

Orchids.—Messrs. Stuart Low and Co.

Narcissi.—Messrs. Barr and Sons, R. H. Bath, and W. F. M. Copeland.

Primulas.—Mr. J. Douglas.

Rhododendrons.—Messrs. R. Gill and Sons.

Shrubs and Alpines.—Messrs. Cutbush and Hillier and Sons.

Topiary.—Mr. John Klinkert.

Tulips.—Maytham Gardens.

Violets.—Mr. Baldwin Pinney.

NEW AND RARE PLANTS.

HIPPEASTRUM PINK BLOSSOM.—A magnificent variety bearing two large and showy flowers on a stout leafless scape. The flowers were almost 7ins. across and of good form. The spreading petals were of a delicate shade of pink shading to white in the throat. This variety is characteristic both from its colour and the beautiful markings on the petals. Award of merit. Shown by Sir George Holford, Westonbirt.

HIPPEASTRUM ICEBERG.—Another handsome variety bearing two beautiful white blooms. The spreading perianth segments, all equal in size, are pure white in colour, shading to light green at the base. Award of merit. Shown by Sir George Holford.

HIPPEASTRUM BLACK BEAUTY.—This variety bore two flowers slightly smaller in size. The segments of the perianth were of a dark red colour, which became darker towards the inside of the throat. The segments were all of the texture of what one might term a satiny velvet, lending to the flower a handsome appearance. Award of merit. Shown by Sir George Holford.

STACHYURUS PRÆCOX.—Flowering sprays of this hardy shrub, a native of Japan, attracted considerable attention. The flowers are borne from fifteen to twenty together in stiff drooping racemes which are from 3ins. to 4ins. long. The flowers are small and pale yellow in colour. Award of merit. Shown by the Hon. Vicary Gibbs.

STACHYURUS CHINENSIS.—The Chinese representative of the genus, introduced to this country by Wilson in 1900. There is little difference between the species, save that probably this species is less elegant than its Japanese cousin. The flowering sprays, bearing almost the same number of flowers as præcox and of the same length, were not so stiff, but more or less dangled or flopped from the branches. The flowers are again small and pale yellow in colour. Award of merit. Shown by the Hon. Vicary Gibbs.

BERBERIS STENOPHYLLA COCCINEA.—This variety of one of the most useful hybrids in the berberis family should prove to be a most useful one from the commercial point of view. The flowering sprays exhibited showed the grace of habit of the type combined with its floriferousness. The interlacing branches bear numerous flowers of a fine rich red colour which wreathe the stems from end to end. Award of merit. Shown by the Hon. Vicary Gibbs.

PRUNUS SARGENTII.—Flowering sprays of this most beautiful cherry merited the attention it received. The branches were laden with blossoms of a lovely deep blush pink colour in clusters of four to six. The flowers are carried on long stalks, from which they dangle gracefully. Each is typically rosaceous in shape, carrying stamens of a deep rose colour. It is undoubtedly one of the most handsome species we have in

Digitized by Google

cultivation in this country. First-class certificate. Shown by the Hon. Vicary Gibbs.

RHODODENDRON SPÆRANTHUM.—A delightful species of the Cephalanthum series discovered by Forrest in 1914. It is a dwarf, somewhat twiggy shrub, only reaching 2–3ft. in height. The leaves are small and aromatic. Numerous small flowers of a whitish to rose colour are clustered together on the terminal branches, resembling a daphne. Award of merit. Shown by the Marquess of Headfort, County Meath, Ireland.

RHODODENDRON ELSÆ.—This is a hybrid between R. grande and R. Falconeri, which combines the graceful and excellent qualities of these two species. Large bell-shaped flowers 2ins. or so across are borne in a somewhat tight truss. They are pure white in colour, with a deep wine-coloured blotch at the base. Award of merit. Shown by Mr. George Reuthe, Keston.

RHODODENDRON MURIEL —This is another handsome hybrid, bearing large and fairly tight trusses of beautiful white waxen bell-shaped flowers. At the base of each of the petals is a deep crimson blotch. The petioles are characteristically hairy. The foliage is of the Falconeri type, being covered with a rust-coloured felt on the underside. Award of merit. Shown by Lady Loder, Leonardslee.

RHODODENDRON GARNET.—This is one of the Javanese hybrid rhododendrons between R. javanicum and R. jasminiflorum var. Garnet. It has all the characteristics of this class, forming a twiggy bush carrying loose trusses of deep red flowers which are flat and spreading. It forms rather a fascinating pot plant, providing a good contrast between the deep colour of the blossoms and the light green of the foliage. Award of merit. Shown by Sir George Holford, Westonbirt.

ROSE ROSELANDIA. — A charming new variety, a sport from Golden Ophelia, upon which it is certainly an improvement—to be added to our already extensive list of hybrid teas. The well formed and large blooms are borne singly on long erect and stiff stems. They are of a sulphur yellow colour, deeper than the original, and have a slight fragrance. The habit of growth and the foliage are good, and showed the results of careful cultivation. It appears to be a free-flowering variety which should find popularity among rose enthusiasts. Award of merit. Shown by Messrs. Walter Stevens, Limited, Hoddesdon.

IRIS WATTII.—A species which comes from Assam and south-western China, which shows an extraordinary habit of growth, long flowering stems, 2ft. or more in length bearing a tuft of five to seven tiny strap-shaped leaves, being formed every year. These bear a branching inflorescence of white flowers. In shape they are similar to those of Iris japonica. The falls are characterised by bearing an oblong blade with a wavy edge, with a small orange blotch. The branching style is to be seen rising prominently in the centre of the flower. Award of merit. Shown by W. H. Walters, Cheltenham.

GLADIOLUS MACKINDERI.—This handsome variety bears a loose spike of flowers on stems almost 3ft. in height. The flowers are of a graceful form and are a delicate fiery red in colour. Award of merit. Shown by Sir John F. Ramsden, Bulstrode Park, Bucks.

ORCHIDS.

ODONTIODA ORESTES VAR. BUTTERFLY (O. Coronation × Odontoglossum percultum).—A showy hybrid with a graceful spike of seventeen flowers of medium size, the segments blotched with red-scarlet, the petals having an additional zone of similar colour near the margin; labellum with a whitish apex, and the spiny crest bright yellow. From Mr. J. J. Bolton, Claygate, Surrey. First-class certificate.

LÆLIO-CATTLEYA ORANGE BLOSSOM VAR. MAGNIFICA (L.-C. Elinor × L.-C. Trimyra).—One of the most attractive of Lælio-Cattleyas, the spike bore five flowers of a uniform apricot-yellow colour, the labellum slightly darker and with an orange-yellow throat. From Lieutenant-Colonel Sir George Holford, K.C.V.O., Westonbirt, Tetbury, Glos. Award of merit.

CATTLEYA SCHRŒDERÆ VAR. HERCULES.—Although this plant has been cultivated in England for many years, it is not until the present occasion that its flowers have been seen at their best. It belongs to the alba section, the broadly developed segments being entirely without colour, except for the usual light orange-coloured area on the labellum. From Messrs. Stuart Low and Co., Jarvisbrook, Sussex. Award of merit.

THE MIDLAND DAFFODIL SHOW

THE twenty-fifth show, or, to be more accurate, what ought to have been the twenty-fifth, had we no war, took place on April 22nd and 23rd in its old home, the Botanical Gardens, Edgbaston, Birmingham. No place in the world has quite the same claim to the tender regard of all lovers of the daffodil. It was here that the first daffodil show, I think I may say in the world, was held in the year 1893 at the suggestion and under the guidance of the late William Hillhouse, my old Cambridge coach for the Science Tripos, who with the passing of the years had now become Professor of Botany in Birmingham University and secretary of the Botanical Gardens. These early shows were the eocene times of daffodil shows. To be somewhat Irish, there are still with us living fossils of this distant past. Deepest down in the strata is my good friend Duncan Pearson—Daffodil Pearson his friends call him. Present as an exibitor at this first show, he has been at Birmingham every year since in that capacity or as a visitor; first in the Hillhouse era, then in the Sydenham era, and lastly in the Smith era.

To mark this occasion the Royal Horticultural Society sent a deputation for the third time in our history to visit the Show. Actions speak louder than words. Their verdict was expressed by their awarding no fewer than three gold medals, one silver-gilt Flora, silver-gilt Banksian, beside others of lesser value. No bad record for any exhibition. This twenty-fifth anniversary was also marked by the giving of the gold medal of the Society to Mr. Herbert Smith. Only once before has this signal honour been bestowed on a member, and that was when the Rev. G. H. Engleheart retired from the office of president. Mr. Smith has been secretary ever since the Society was founded by Robert Sydenham, and the amount of work that he has done for us nobody knows except who, like myself, are familiar with its internal machinery. It was a proud day in my life to preside as president at the official luncheon to the Royal Horticultural Society's deputation (Messrs. E. A. Bowles, W. R. Dykes and R. Cory) and to make the presentation to Mr. Smith. In my little speech I could not refrain from tilting at the article on white daffodils which had appeared in the *Morning Post* on the day before (April 21st). I can only suppose that the writer must have a grudge against the editor, for the little bit of it that really touched upon white daffodils was as full of errors as an egg is full of meat, and that the editor never read it or was totally ignorant of daffodil history. Mr. Richardson did not raise Beersheba. It was raised by Mr. Engleheart. White daffodils are not a twentieth century novelty, as anyone knows who has ever looked at his Parkinson or who is familiar with the work of William Baylor Hartland of Cork, or is aware that it was the Narcissus poeticus that was first called a daffodil.

Were everyone of that writer's opinion, there would be " no use " for daffodil shows—that is to say for man-made flowers. Why, I ask, do people so often " sware by " flowers that are the result of impersonal agents and pooh-pooh those made by living agents? We do not all do this, and so we have our daffodil gatherings such as we have just had at Birmingham.

Beersheba, the fine white trumpet of Engleheart, could be compared on this occasion with old varieties like albicans. I give the unknown writer a present of all the albicans, as I suppose he would give me all the Beershebas—*Chacun à son gout*. Albicans was one of a group got together at considerable trouble by Miss Pope, a daughter of the man who will go down to posterity as the man who set the big price ball rolling when he gave £100 for four bulbs of Will Scarlett. It was composed of the old varieties that were in vogue when the Midland shows started, *e.g.*, Edward Hart Beatrice, William Wilks, Agnes Barr, Grand Duchess and Hodsock's Pride. Few know them now. Yet I can remember our first shows when we thought as much of some of these as we now do of Royalist, Kantara, Dinkie and Beauty of Radnor. There were some wonderful flowers on view this year. One cannot name them all, or even a tithe of those I would like to do. Some for the very good reason that they are at present only under numbers; others because the space allotted me is not elastic. Still, I will do what I can, and if I seem to ignore the fine groups " not for competition " and the good individual exhibits in the competitive classes, it is not because I could not say much to their credit, but because I have a feeling that readers want to know more about the individuals than the mass.

After our little dinner at the Grand Hotel on the first day of the show, Mr. Herbert Chapman suggested that it would be most interesting for everyone to name what they considered the best flower in the show. We did so, with the result that the giant yellow self incomparabilis Wheel of Fortune came out first, Beersheba and Tenedos (a stellate giant Leedsii) second, with the following as equal third: Mystic, Lily of Rotherside and Resplendent. Wheel of Fortune is featured in one of the pictures that accompany this article. It is a soft yellow self of fine form and symmetrical build, with a slight recurve to the cup. Beersheba is a magnificent white trumpet. Tenedos is a very large giant Leedsii, and I have read that Brodie of Brodie thinks it one of the most remarkable flowers in his unique collection. Mystic is a most dainty small-cupped Leedsii with a conspicuous pink rim to the cup. I do not wonder that Mr. Wilson has been told that it is doubtful if it is not the most beautiful seedling he has raised. Lily of Rotherside is a white Leedsii raised by Mr. Chapman—it is a most refined flower. One must not, however, paint the lily. Resplendent is a striking Barrii or possibly incomparabilis with pure poeticus white perianth and a large red flattish corona irregularly marked with red blotches.

Digitized by Google

The second of the illustrations is a New Zealander—Silver Plane. It is of a very unusual shape for a Giant Leedsii with its large flat corona, which is of a decided yellow tone. It is one of the best of all New Zealand raised daffodils. This opinion of mine was confirmed by a keen daffodil visitor, Mrs. Trevena from Dunedin. It is recognised in the Dominion as one of poor Mr. Lowe's finest flowers. It was instructive to hear from this lady her opinion of our home flowers compared with those raised there. She said in big yellow incomparabilis and in Giant Leedsiis they were quite our equals, but in all else, especially in big red bowls, we outdistanced them. I have never seen so much good colour in such a small space as in Dr. Lower's group. It fascinated Mrs. Trevena. She always seemed to be in front of it on the second morning. It *was* good. Here is a rough idea of its coloured contents: Ten all red bowls of which Merkara was my favourite; two red (?) perianths, John Peel being the best; five wide bold red edges of which Golconda appealed to me very much. No wonder the group was awarded a gold by the R.H.S.

Among other flowers new to me I noted an extremely taking, very loosely built double white in Messrs. Barr and Sons' group. It will have a future, I feel sure, for decorative purposes. It is named Snow-sprite. Then John Bushby and Gallipoli, with their drooping flowers reminiscent of Will Scarlett, were always catching my eye as I passed them. They are decorative rather than florist in their general appearance.

The half-brothers Tapin (a bicolor trumpet) and Primrose Knight (a deep primrose and soft pale yellow trumpet) were examples of what show trumpets should be, fit in every way to associate with the famous Royalist. (What a collection Beersheba, White Knight, Carmel, Royalist, Primrose Knight and Yukon would make!).

Dactyl, a shapely green-eyed poet, and Dinkie, a greeny yellow Barrii, end my selections. Were I in want of bulbs, I would say "Let them all come"—but what about my pocket?

JOSEPH JACOB.

NORFOLK AND NORWICH HORTICULTURAL SOCIETY

THE spring show of this Society was held on April 16th at the Drill Hall, Norwich. The weather conditions were not at all favourable, consequently the attendance was not so large as expected.

In the classes for narcissi, Captain J. H. Mander took the leading position, staging many of his own raised seedlings under numbers and they comprised almost every type. Many of these numbered seedlings possessed qualities that bid well for further development, this remark especially applying to the trumpet and Barrii sections. Captain Sandys Winsch staged some very good blooms of the leading named varieties

The best collection of flowering shrubs came from Mr. J. A. Christie, M.P., Framingham Manor.

Carnations were not so strong a feature as one might have expected, the best lot being staged by the Misses McLintock. Polyanthus, violets and wallflowers added to the charm of the spring flowers.

Pot plants were a good feature. A group set up by the Norwich Corporation Parks Department was a striking feature of dainty, effective arrangement. Mrs. H. J. Copeman, Westwood House, Norwich, staged splendid examples of cinerarias, both stellata and ordinary, herbaceous calceolarias, azaleas and primulas and she was also first in the fern class for a fine plant of Asplenium australasicum. Mr. J. E. Moxey exhibited a wonderful plant of Azalea fragrantissima. The classes for lily of the valley, mignonette, schizanthus, primulas, etc., brought exhibits that added their quota to the beauty of the show.

Fruit and vegetables were not so numerous as one could have wished to see. Special mention is due to the collection of vegetables staged by Mr. Gordon Lang, Plumstead; it contained fine examples of forced beans, peas and asparagus.

The trade growers did much to enhance the beauty of the show. Messrs. Daniels Bros., Limited, Norwich, had a wonderful array of forced shrubs, besides a fine collection of the best narcissi. They also made a feature of polyanthus and anemones.

Messrs. A. J. and C. Allen, Norwich, had a fine group of roses in pots of several types, the dainty polyantha section being very prominent.

SIMPLE GARDENING

STRAWBERRIES.

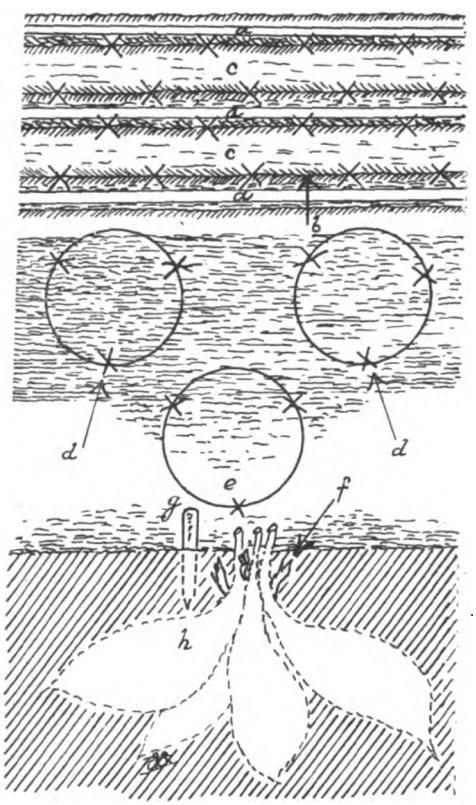
WHERE littery manure is available in quantity it is used liberally in the late autumn to surface-mulch the strawberry beds. It keeps the roots warm, preventing frost reaching them in a severe degree, and, when the thaw comes, acts as a shield to the sun's rays while the soil is in a frozen state. At the present time this littery manure will have lessened in bulk considerably, only the freshest portion of the straw remaining. This will be quite clean, washed by the winter's rains, and should not be disturbed, as it will prevent the ripening fruits getting soiled later on. But it is a wise plan to examine carefully the crowns of all plants now and remove any soil, leaves or other foreign matter found lodging on them, scratched there, possibly, by birds. This is also a good time to put on the final layer of straw, hay or quite littery manure as a protection to the fruits in due course. The litter will get well beaten down before the fruit ripens. Strong plants, put out a year ago last July and August, yield the finest fruits, and if a few are required for exhibition they will be larger if any small side crowns are now removed. Remove also the smallest berries on the central stem while they are quite small. All necessary supports for the nets should be placed in position now. Fine wire netting round the sides saves the string nets from rotting on the ground.

WATER LILIES IN TANKS AND TUBS.

Water lilies are liked by everybody—by those who possess means for growing them on a large scale in very natural surroundings, and by those who possess a small formal garden in town or suburb. Perhaps the majority of the latter are the most enthusiastic. Of course, where convenient, a tiny tank-pond can be cunningly arranged so that it will appear to be quite natural. Whether tank or tub be used, it should be sunk into the ground to half or two-thirds its depth. It looks much better about 1ft. above the ground than placed on the ground level. Half-sized casks, or full-sized casks cut to form two tubs, are the best. The insides should be charred: this is done by placing shavings or paper, saturated with paraffin, in the vessel, lighting and allowing the material to burn till the sides are nicely charred, then suddenly turning over the tub to put out the flames. Tubs so treated will last many years. The position should be one open to the sun; and the water supply, too, must be considered. A tiny trickle in and overflow will be sufficient; failing this, fresh water must be placed in at least twice a week—not necessarily all fresh. Turves, in which the grass has died, should be placed in the bottom, and the plants secured there by placing bricks to prevent the roots being disturbed. The tanks should be cement or stone ones, not iron. Some good varieties of water lilies which are easy to grow are Nymphæa alba, white; NN. odorata Luciana, blush pink; Laydekeri purpurea, deep rosy crimson; and Nuphar luteum, yellow English water lily. These are very reasonable in price.

PLANTING OLD DAHLIA TUBERS.

Perhaps four cultivators plant old tubers to one who plants newly rooted cuttings; but, whether young or old roots are planted, it is advisable to prepare and treat the ground in the same way. Old tubers may be planted early in May, but young plants must not be planted before danger of frost is past—in June. The soil should not be trodden upon after the dahlias are planted. If planted in rows, the following rules should be observed: In the sketch, *a*, *a*, *a* show the narrow paths between



beds *b* and *c*, *c*; two rows in each bed, each row of plants can be attended to without treading on the bed itself. If the young shoots come through the soil early, some of the latter should be drawn up to form a ridge as shown at *b*. Group planting is shown at *d*, *d*, *e*; the crosses represent plants. The lower sketch shows how deep to plant: *f*, young shoots growing through the soil. Labels should be placed clear of the plants, shown at *g*, and not driven into the tubers, *h*. Supporting stakes, too, should be driven into the ground about 16ins. from the old tubers.

HERBS.

With a few exceptions, herbs are not grown as carefully now in private gardens as they were a generation or two ago. The herb garden used to be a feature, and the variety lent additional interest. In large gardens more herbs may be grown than in small ones, but in the latter the following should have place and be well grown: parsley, mint, thyme (common), sage, rue, pot marjoram, fennel, horehound and hyssop. With the exception of mint, all the above may be grown luxuriantly from seeds. Mint should be grown in a naturally moist soil and from roots, not seeds; the roots are similar to those of the couch grass and grow almost as freely in a suitable medium. It is only necessary to lay the roots flat in shallow drills and cover them with 2ins. of soil. Parsley, too, should be grown in a moist soil if it fails in light, and *vice versa*. This plant does fail to thrive in some soil, and it is always wise to grow it in several parts of the same garden. The majority of the herbs like a medium light soil and a sunny position. I may say, here, that herbs should be gathered for storing when in flower, as they are then at full strength. A medium rich soil is best, and the plants should be grown in it in beds or rows. Keep the soil free from weeds, and the herb garden will look all the more inviting. Old clumps of thyme are readily made to yield hundreds of young rooted plants by layering, placing soil in the centre of each clump. Sage seeds attract mice as aniseed does dogs.

PEACH TREES UNDER GLASS

When one enters a peach house one wishes to know what to do to the trees in order that one may reap a full crop of highly coloured fruits. Peach trees may be very successfully grown under glass without any fire heat. Unless forcing is the object in view, I prefer to grow the fruits without fire heat. Young shoots are now growing freely, and it is of the highest importance that they should not be overcrowded. The young shoot of this season becomes the fruit-bearing branch of next year. These young shoots should not be closer together than 4ins.; 6ins. would be better. The fruits, on healthy trees, should be evenly thinned out so that there is one to each square foot, approximately. The fruits retained should be on the top side of the branch, and then it will get the maximum amount of sun, be highly coloured and of richer flavour. Clean trees are essential. Daily syringings do good, judicious watering and feeding too. Ventilation should be well attended to, then we secure those big, thick, dark green leaves so much prized. A small sprinkling of soot on the border once a week will assist in keeping down red spider, the ammonia arising from it being bad for the spider and good for the foliage. Aphides should be kept in check, too, by fumigating regularly once a fortnight. It is most important that every care and precaution should be taken during the next few months so that a good crop of fruit is obtained. Bad methods of cultivation and lack of attention to the crop when pests make their appearance are generally responsible for poor crops.

GEORGE GARNER.

CORRESPONDENCE

NOTES ON VIBURNUMS.

SIR,—I was much interested in the "Notes on Some Viburnums" in the issue of THE GARDEN of April 18th. It may be of interest to your readers to know that Viburnum fragrans fruited in my garden last year for the first time. This was one of the original plants raised by me from Farrer's seed. "E. H. M. C." omitted Viburnum bitchuense, which is in my opinion by far the best of all the viburnums. It is much after the style of V. Carlesii, but has much bigger flowers and grows into a larger bush. The flowers are white, but one of its attractions is that the buds are bright pink before they open.—F. C. STERN.

BLACK CURRANTS.

SIR,—I desire to thank "A. H." for calling attention to the Baldwin variety of black currant on page 222 of THE GARDEN. My experience coincides with his in certain respects and explains the reason why I did not recommend it. Late frosts mar the prospects of success in many seasons by destroying the essential organs of the flowers. Baldwin is the earliest black currant to bloom. If the contour of the plantation gives natural protection, much loss will be prevented. Every garden is not favourably placed in this respect, however, and the application of artificial protection would not be an economic proposition, I fear. I thoroughly agree with "A. H." that there are few fixed strains of Baldwin, and I congratulate him upon having worked up a reliable stock for which there is such a vigorous demand. It would be interesting to know if Baldwin is more liable to variation than other varieties. I know of none which gives such a large percentage of outsiders. One can scarcely think that the ordinary channels of commerce will ever absorb large quantities of Baldwin on account of the reddish colour of the berries when ripe. Colour does not count for much in the manufacture of preserve, but it does in shop and market trade. The public demand a black currant which is really black.—GEO. H. COPLEY.

RIBES LAURIFOLIUM.

SIR,—The flowering of Ribes laurifolium in the Royal Botanic Garden, Edinburgh, prompts the writing of this note. Although it cannot be reckoned a decorative plant, so far as its flowers are concerned, it is well worthy of cultivation, partly on account of the earliness of its flowering and partly for its foliage.

It received an award of merit from the Royal Horticultural Society, when the Hon. Vicary Gibbs exhibited it on February 20th, 1912. It had been raised at Aldenham, from seed sent home by E. H. Wilson, who collected it in western Szechuan, where the plant occurred among rocks at an altitude of 5,000ft. It is, in habit of growth, by nature dwarf and spreading, and is said to attain a height of about 6ft., so that it should be an excellent subject for the higher parts of the rock garden. The leaves are ovate-lanceolate, evergreen, and rather thick. They are of a fine dark green colour, and when full grown tinged with a pleasing purple shade at the margins, which are toothed.

The flowers are yellowish green in colour and carried in axillary racemes, which make their appearance in February or March. They possess rather large pale green bracts, which are quite distinctive.

The plant may be reckoned as hardy, although it appreciates a little shelter. It is recorded (Journal R.H.S., XXXVIII, page liv.) that plants growing at Aldenham in an exposed position suffered no damage, although on two occasions during the previous winter between 20° and 30° of frost were registered. It is planted in a sheltered part of the rock garden at Edinburgh, where it appears to do quite well.

There are good illustrations of the plant in the *Botanical Magazine*, t. 8543, and the *Gardeners' Chronicle*, III, 55, page 239. —R. H. JEFFERS.

NATIVE PLANTS.

SIR,—I was much interested in your leader on the above subject (page 167), and quite agree that many of the British alpine plants are difficult to cultivate. Gathering only a few specimens, or perhaps only one of a rare plant, I had little opportunity for making many experiments. There is more in it than the question of food, seeing that the plants were mostly grown in pots, and in all cases first established in pots. The saxifrages were as puzzling as any. From spring till the plants were put in a cold frame Saxifraga cernua, S. hypnoides, S. nivalis, S. aizoides and S. oppositifolia throve well; but after being put in the frame with top ventilation they began to damp off wholesale. S. cernua, found on one very restricted area of a mountain top, when kept in a cold frame during summer, developed a rosette of leaves from each bulbil, and by autumn had no reserves with which to continue growth the following year and promptly died. Other bulbils grown in a pot, fully exposed on the balustrade at the top of a three-storey house all winter, flowered beautifully the following summer. Climate and full exposure seemed to play its part here. Salix lanata in a pot in a cold frame got on well till the summer got really warm, when it died suddenly. The other species succeeded well in the open for a time, and S. Andersoniana and S. phylicifolia produced hybrids which sowed themselves spontaneously and flowered in two or three years' time. S. Myrsinites, S. Lapponum, S. reticulata, S. herbacea and a hybrid between the latter and S. Arbuscula all flowered. The first named made two or three distinct growths a year, but after a mild winter it came into growth in March and got all its leaves destroyed by a late frost, from which it never completely recovered. Tofieldia palustris throve well till one year when I re-potted it in rather heavy loam, when it gradually died. Draba rupestris in pots or pans made a showy plant, but in the open became seedy, weedy and sowed itself, but was uninteresting, owing to few flowers scattered on long stems.—J. F.

GORSE.

SIR,—The discussion of this subject by Dr. R. Lloyd Praeger (page 172) was very full and highly interesting, and if permitted I would like to add a few observations which I have made. The vindictive thorniness of the common gorse is an effective protection against all domesticated or farm animals, but in some rabbit warrens, where other vegetation is scarce, the gorse often fares badly, especially after it gets burnt by accident or otherwise cut down, for the rabbits then keep it very closely eaten down. I have seen one of the gorse mills mentioned by Dr. Praeger in a hilly part of Scotland. It consisted of a stone very like an upper millstone, with a hole in the centre. Attached to a long shaft, a horse travelled round a circular course in which the gorse was laid, so that the big stone crushed it, as the stone followed the horse at the other end of the shaft. It is indeed difficult to make gorse happy in a garden, because it loves the wind on the open sandy heath; but the double gorse grows compactly and flowers profusely on a sandy mound in Kew Gardens. Seedlings of the common gorse behave erratically in producing simple or compound leaves, as stated, but a good proportion of them have simple leaves, narrower than the seed leaves, and gradually becoming smaller till reduced to spine-like organs on stems only 2ins. to 3ins. high. The broom produces compound leaves from the first, rarely producing a large, simple leaf. I can see only one on fifteen seedlings.—HORTUS.

COLLECTING PLANTS

IN this issue will be found the second portion of Mr. H. Stuart Thompson's article on plant holidays. There is nothing I can add to such an expert's advice except, perhaps, a few words on the actual collecting of plants and their identification. It is obvious from the increasing numbers of gardening enthusiasts who collect plants for their own gardens, whether at home or abroad, that everyone feels a satisfaction in growing plants which they have found for themselves and dug up with their own hands. There is something personal in the feeling that a collector has for a plant found by himself. He shows it off with pride and tends it with the greatest care, which is only natural, for there is nothing like a plant for recalling a happy day spent in the mountains.

In collecting plants three things are necessary in the field: something in which to carry them, something with which to dig them up, and a supply of labels. The main necessity in a receptacle is that it should be easy to carry; a fishing basket is excellent provided that it is curved so as to fit your shoulders, and the same thing applies to a collecting tin. Both of these are better than a bag or rucksack, for, being rigid, the plants can be packed tighter and are not so easily bruised or broken. A trowel is an absolute necessity if the roots are to be dug up without serious damage. Farrer invented a trowel which was by far the best for the work in the field. Instead of widening towards the handle, it was the same width throughout its length; the blade measured about 8ins. by 2ins. I believe that trowels after his pattern used to be sold by the Army and Navy Stores, but I do not know if they are still stocked. The labels should have a sufficient length of string attached to enable you to tie them firmly to a good-sized plant.

It may appear to be finicky to say that labels are a necessity, but this is really not the case. It is impossible even on a single day's excursion to remember exact details about each plant, and in order that it may have every chance in your garden, conditions should be approximated as nearly as possible. Every specimen should be clearly labelled with colour of flower, position, soil, water, sun or shade, orientation, altitude, if solitary or in clumps, and, if possible, what its near associates are. These are all important if its well-being in a home garden is to be catered for.

When you actually dig up a plant, make sure that you are taking sufficient roots and are disturbing them as little as possible. Thus, in an alpine meadow a wedge of turf should be dug up with the plant, a little moss with a plant from a rock, and so on. In most cases it will live quite happily with no attention for a fortnight or more, if it is collected in this way. When they are packed for transport home, they should be packed as tightly as possible.

Although thorough identification requires a botanical training, yet it is both instructive and amusing to try to name the plants you have collected. It is a mistake to imagine that a library is a necessity; for one thing, the more authorities you use the more muddled you will become. For British plants the beginner would do well to use "Haywards Botanists' Pocket Book" (Bell and Sons, 5s. net); while the gardener with some idea of families and genera will find Bentham and Hooker's "British Flora," 2 vols. (L. Reeve, 12s. net each), by far the most complete and useful. In the same way, in the Alps an invaluable book for the beginner who only wants to name his finds approximately is "The Alpine Flora for Tourists and Amateur Botanists," by Dr. Julius Hoffman, translated by E. S. Barton, with 283 coloured figures, new edition (Longman's, Green, 1925, 12s. 6d. net). The plates are particularly good, and for those to whom collecting is only a side line on a holiday, this small book is all that is necessary. Again, for those who are more advanced there are two splendid volumes by Mr. H. S. Thompson, the author of our articles, called "Alpine Plants of Europe" and "Sub-Alpine Plants of the Swiss Woods and Meadows" (the title of the latter, by the way, is a little misleading, for it covers a great part of Europe), numerous coloured plates (George Routledge and Sons, Limited, 10s. 6d. net each). Both of these volumes are exceedingly well planned and are very complete. All these books have glossaries attached which give simple definitions of botanical terms used in them.

This is not a large outfit to take away on a plant-collecting trip—a basket or tin, always useful for holding odds and ends, a trowel, labels and, at the most, two volumes.

One warning I should like to give to all would-be collectors: respect the plants and the ground in which you find them. Do not dig up more than you mean to carry away with you, and always smooth over the ground and replant any neighbours which you may disturb in removing something you fancy. Nature makes just as fine or better a garden than you can, though it may be untended.

CARNATIONS AND PINKS

DURING RECENT YEARS THE POPULARITY OF THESE CHARMING GARDEN SUBJECTS HAS INCREASED ENORMOUSLY, TO A GREAT EXTENT DUE TO THE LARGE NUMBER OF EXCELLENT NEW VARIETIES

IN common with all our popular flowers, both carnations and pinks have been greatly improved during recent years. The modern border carnation has not only a stronger and more upright stem, but there are fewer varieties inclined to split their calyces, and a wider range of colour has been obtained. Fragrance and hardiness have been preserved, and it can be truly said that, when well grown, there is no more delightful subject for the open border than the border carnation. It is far too often treated as though it were not a hardy plant. It will stand the rigours of winter in almost any part of our land, and if the plants are left undisturbed the wealth of bloom in the second season is a revelation.

The perpetual-flowering carnation is virtually a greenhouse subject, although it can be grown out of doors in the south with a certain amount of success. Its continuous blooming is one of its greatest assets, and on this point it scores over the border carnation.

The perpetual borders, or hybrid borders as they should be more correctly termed, bid fair to become popular. They have many desirable qualities, some of which are not yet recognised by many carnation lovers.

In pinks we have one or two new types that are already prime favourites. The well known Allwoodii has the habit of the pink, but a perpetual-flowering character which it inherits from one of its parents. Dianthi Herbertii have no carnation blood in them, but they have a very long blooming period, and the flowers are famous for their fine form and fragrance. The Pritchard pinks are another splendid new race, and they comprise many rich shades.

THE BORDER CARNATION.

It will be generally agreed that, taken as a whole, the border carnation represents the best formed flower. The petals are clearly cut at the edges, and in the best types they are of splendid texture. In the best varieties, too, they are not too numerous or closely packed, so that the flower has a good chance of opening without "balling" or splitting the calyx. The evolution of a strain that has been well named "Cloves" has been instrumental in combining fragrance with the best attributes of the border varieties. I am not quite sure whether our hybridists, in trying to produce new shades, are not rather overdoing the fancy section and giving us many mixtures of colours that may be unique but are not altogether pleasing. That is, however, perhaps a matter of individual taste.

THE HYBRID BORDERS.

These are only new in so far as they have been in commerce but a few years. They have been in existence for a quarter of a century. Messrs. Allwood Brothers of Haywards Heath were the first to introduce them to the gardening public, and with one exception all the varieties that they list, I believe, are of their own raising. The exception is the variety Avondale, which was raised by the late Major Paterson, and named after his residence, some fifteen years ago. Messrs. Allwood Brothers have, doubtless, improved the original stock since it first came into their hands, and it is now listed as Sussex Avondale. I have grown practically all the Sussex varieties together with a large number of seedlings from other sources, and from my experience of them, both in the open and under glass, I am convinced that they are a coming race. Messrs. Allwood's varieties are a particularly good and useful strain. Many of them represent an excellently formed flower, *e.g.*, Sussex Pink (possibly the nearest approach to the form of a border variety of any that are at present in commerce), Sussex Supreme, Sussex Idol, Highland Lassie, Rosalind, Sussex Crimson and Sussex Scarlet. The newer introductions are particularly strong in the stem, and some of them, such as Sussex Leander and Sussex Cerise, are very floriferous.

In the seedlings that I have tried during the last two years there has been rapid evolution as regards the attainment of dwarf, bushy habit, regularity of form and smoothness of petal, the retention of fragrance and the production of many pleasing self colours. Several whites and salmon pinks appeared in the last batch, and there is already a big range of scarlet and cerise shades, together with many beautiful fancies both on white and yellow grounds. A yellow variety has also been produced.

The hybrids can be lifted from the open border in the same way as chrysanthemums, and when treated in this way they will give a succession of bloom if kept free from frost.

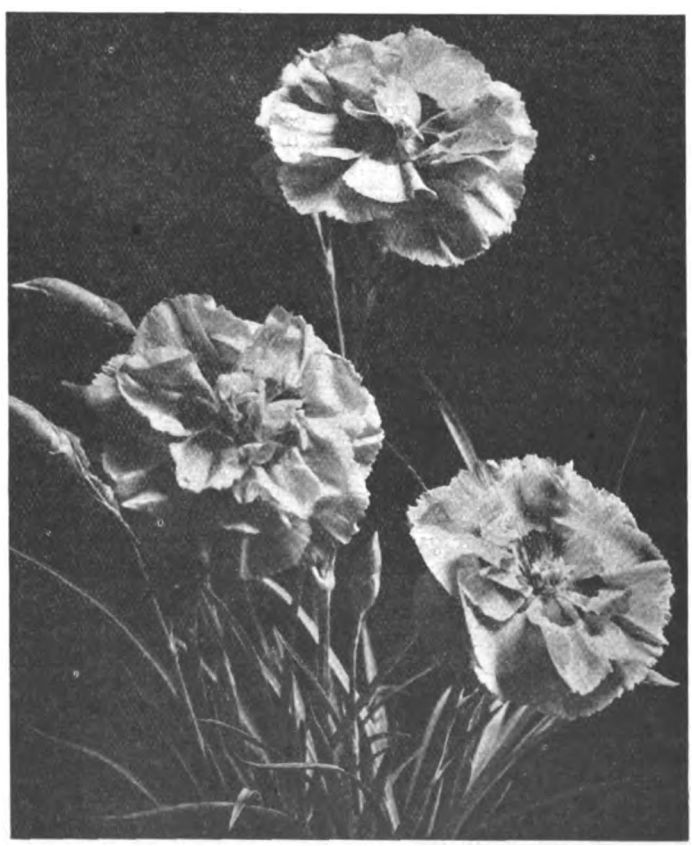
DIANTHUS ALLWOODII.

These are very easily grown subjects, and will thrive in any soil if they are given a sunny situation. They soon make big plants and, as they strike readily from cuttings, a big stock can easily be obtained from an initial outlay of a few plants. During the summer they can be propagated without the aid of glass if they are inserted in a sandy soil and given a shady place until root action commences.

There are now many pleasant self colours, and those varieties that have a distinct central zone or "eye" are very pretty. In the self shades Harold is a very popular white, Marion is a lovely shade of pink resembling the Rose Dorothy Perkins, Hugh is a distinct crimson-purple, and Maud, Nell and Vera are different shades of pink. The latter is a good variety for rockwork. In the varieties that have a central colour zone Susan, Betty, Eleanor and Joan are all excellent.

DIANTHUS HERBERTII.

I believe that there is a great future in store for Mr. Herbert's pinks. Since the original variety, Progress, appeared as the result of crossing two of the laced pinks, many beautiful shades have been produced. Of the moderately priced varieties I can particularly recommend Queen Mary (rosy pink with deep crimson base), Model (rosy pink with deep red base), Mrs. G. Walker (bright pink and rosy red), Victory (deep ruby crimson), The Imp (dark crimson),



PERPETUAL FLOWERING PINK (HERBERTII) QUEEN MARY WITH ROSY PINK BLOOMS.

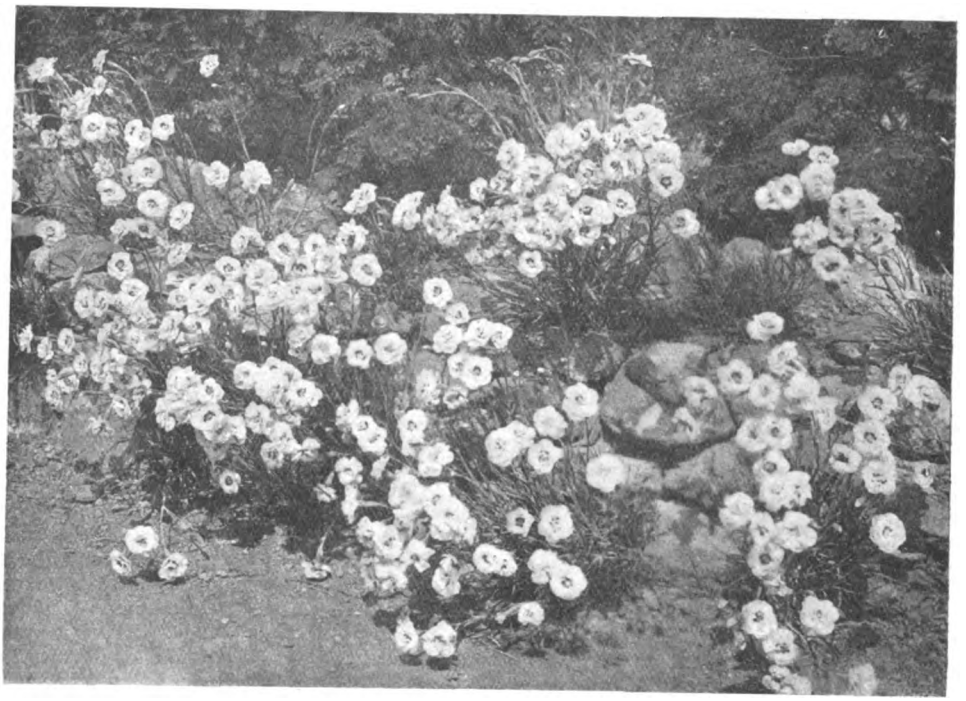
Digitized by Google

May Queen (bright pink), Lyric (purple) and Gertrude (rosy mauve).

Mr. Herbert tells me that he now has scarlets, white, pink, crimsons in various shades, purple, buff and colours hitherto not seen in any carnation or pink. There are several salmon and intermediate shades, but no yellow as yet. It is certain that during the next few years we shall see great developments in this magnificent strain.

A FEW WORDS ABOUT CULTURE.

Mr. Montagu Allwood is of the opinion that the majority of carnation growers do not realise the fact that carnations love lime and abhor leaf-mould. Those who have admired the wonderful displays from the Wivelsfield nurseries may find much benefit if they will remember his advice. I believe that many growers are often inclined to think that the carnation will thrive if planted indiscriminately in a mixed herbaceous border and left to take its chance. It is probable that tall-growing subjects choke out the light that is essential to its well-being. Give it a sunny situation, sheltered from the winds if you can, but never overhung by trees or shrubs. If the soil has been well prepared to the depth of 1½ft. or 2ft. and a liberal dressing of well rotted animal manure incorporated in the lower spit, providing the soil is rich in lime, that seems all that is necessary to give the plants a good start. Plants may be obtained from the best houses ex pots, so that it is not yet too late to put out a final batch.



CLUMPS OF DIANTHUS ALLWOODII ARE ALWAYS EFFECTIVE IN THE ROCK GARDEN.

My article on "Border Carnations for Autumn Planting" in the issues for November 1st and 8th, 1924, raised a number of points with which I will deal briefly now.

With reference to the variety Gracefulness, one of Mr. Payne's novelties, I wrote, "this is a fine variety for growing under glass, when with the calyx eased and helped occasionally, it can be grown to a very large size," and a correspondent, "Linkman," asks for a more explicit explanation of this. When very large buds are observed these should be slit about one-third of the way down each rib on the calyx. This is known as easing the calyx and helps the bloom to open evenly. Varieties that have a tendency to burst their calyces, *e.g.*, Lord Steyne, Princess Mary, Bookham Flame, etc., give excellent blooms if treated in the way described. I do not think any useful purpose will be served by entering into a controversy about Mr. Morton's criticism of my last article. He merely gives his experiences of certain varieties in contrast to mine. In support of my statement that Bookham Salmon has a strong constitution, Mr. James Douglas, the raiser, states that it is the strongest in the section, the next being Salmon Clove and the next Laverock. Mr. Douglas tells me that since its introduction some 17,000 plants have been grown and distributed, and no complaint of any kind has been made about it.

The form of Margaret Keep may not be perfect as an exhibitor's flower, but it is a neat, compact bloom for the border. That is the place where the *border* carnation should be grown. If grown under glass, where red spider is often a terrible pest and impregnable when once it obtains a footing, an erroneous idea of the merits of a variety is formed. My experiences of border carnations are confined to outdoor-grown plants.

NORMAN LAMBERT.

SEASONABLE WORK AMONG HARDY SHRUBS

THE number and variety of hardy shrubs cultivated in our pleasure grounds and garden borders have vastly increased during the last two or three decades. With the increased interest in this branch of gardening has followed much improved methods of cultivation. Growers of fruit pay special attention to the preparation of the ground, transplanting, mulching and pruning. These operations are equally important for the successful cultivation of shrubs.

In spring, when the roots are in full activity, many shrubs, one might even write all shrubs, benefit by some form of mulching or top-dressing. The mulch may be applied for one of two reasons, or both, *i.e.*, nourishment for the shrubs or to assist in keeping the soil cool and moist during the hot dry days of summer. Decayed farmyard manure is the best mulching to supply most plants with nutriment. If of a heavy nature, it can be mixed advantageously with half-decayed leaf-mould. The mulch for rhododendrons, including azaleas, should be more vegetable than animal litter. For this family of plants spent hot-bed or mushroom-bed manure is useful mixed with leaf-mould.

The question of covering or burying mulchings of manure near the house and in frequented parts of the pleasure grounds and garden may arise. In the case of newly planted shrubs it is generally a simple matter to fork in the dung lightly. With established bushes, however, having many surface roots, it is a mistake to fork the surface indiscriminately. When it is desirable to cover the manure, sprinkle a little fine soil over the top rather than dig it in and destroy endless numbers of fibrous roots in doing so.

THE SPRING PLANTING

of numerous shrubs in a small state is desirable for various reasons. The cistuses, for example, suffer more from cold winds and sudden changes of wet and cold than actual dry frosts. Consequently the plants in pots are afforded the protection of a cold frame or sheltered positions until April is well advanced.

The ceanothuses, both spring-flowering and the summer and autumn blooming hybrids, are mostly found to thrive best when planted during the late spring. Eucalyptus, Hibiscus syriacus and hamamelis will take root in fresh soil, if planted at the end of April onwards into May.

To obtain the full benefit of the beautiful coloured stems, the pruning of the willows, Salix vitellina, the variety britzensis and S. daphnoides can be deferred until towards the end of April.

PRUNING EVERGREENS.

During the second half of April on into May, when shrubs are getting into full activity of growth, is a good time to prune

Digitized by Google

evergreen shrubs. The trimming and shortening of thin branches and twigs may continue, as occasion arises, throughout the summer. When the proposed pruning is to be fairly hard cutting back into the old wood, this is the season of the year to do the work with the most hope of success.

In no other garden operation is the old proverb "A stitch in time saves nine" more applicable than that of pruning, and to the pruning of evergreen bushes in particular. It is often a mistake to pass a bush because it looks satisfactory for the time being. Consider rather the subsequent growth for the next few years. Several inches taken off the ends of the shoots now to induce bushy growth and the laying of a good foundation will, or may, obviate the necessity to cut off as many feet in four or five years' time. This latter will, probably, also mean disfigurement for at least a year.

This is the best season to take in hand neglected holly, yew and other evergreen hedges. It may be desirable to spread the treatment of hedges in very bad condition over a period of two or three years. If the height is to be considerably reduced, do this now, next year cut one side hard back, and the following year deal with the remaining side. Couple with the pruning the cultivation of the surface soil and the application of a good mulch of old decayed manure. Spray severely-pruned hedges morning and evening for a few weeks during hot, sunny weather. In addition water liberally if the soil is dry. Somewhat similar treatment should be afforded to certain evergreens which have outgrown their positions. In the case of flowering shrubs it may mean the loss of a season's blossoms, but if the bushes are to be kept within limits this is inevitable. It will be sufficient to cite three well known examples, *i.e.*, large-leaved rhododendrons, Olearia Haastii and Veronica Traversii.

Certain evergreens planted as hedges require attention in the matter of pruning each year after flowering, notably the laurustinus, Berberis Darwinii and B. stenophylla.

A few early-blooming deciduous shrubs, especially when grown against a wall or fence for protection, benefit by the shortening and thinning of the shoots. These include Chimonanthus fragrans, Loniceras fragrantissima and Standishii, varieties of Cydonia japonica, Jasminum nudiflorum, forsythias, Prunus triloba flore pleno and P. japonica, both double white and pink forms.

One section of forsythias, Fortunei and Sieboldii forms of suspensa, flower better when the young growths are pruned fairly hard back each spring after flowering. The other, represented by F. viridissima and the hybrids F. intermedia vars. spectabilis, densiflora and vitellina, should only have the stronger young shoots shortened.

TRANSPLANTING EVERGREENS.

Because the leaves of evergreen shrubs must have an uninterrupted supply of moisture from the roots throughout the year, though appreciably less in winter, a large number are not so readily transplanted as the deciduous or leaf-losing shrubs.

The best time to lift and transplant these evergreens is when life is very active and the roots can speedily establish themselves in the new positions. Generally this is towards the end of April and during the first half of May, but it varies a little from year to year according to the weather. Obviously, a showery period is ideal for the work, while the moving operations should if possible be suspended during hot, dry and windy weather.

Warm, showery days in May are favourable for the planting of hollies, yews and other evergreens from nurseries. Most growers of these plants for sale pay special attention to frequent transplanting in the home nursery to fit them the better for the journey and safe planting in the purchaser's garden. When there is any appreciable loss of roots, considerable shortening of the leafy twigs is desirable to balance matters somewhat, until the root system again becomes normal.

Evergreen oaks, arbutuses, cistuses, pyracanthas, evergreen ceanothuses and ivies are usually cultivated in pots in nurseries to overcome the difficulties of transplanting. From time to time, however, as these and similar shrubs increase in size thinning must be done, moving to fresh positions being necessary. Though the shrubs may be moved with good balls of soil attached to the roots, make a point of reducing the top growth to balance somewhat the inevitable disturbance of the roots.

The fact of growth starting with renewed energy means active leaf transpiration, hence the sooner the roots get a fresh grip of the soil the better. As soon as convenient after planting a thorough soaking with water is essential with all evergreens. It will help in keeping the ground moist to mulch freely with decayed manure. Further waterings must follow if the weather is dry, and syringe the plants mornings and evenings on hot, sunny days.

Our experience in planting a holly hedge with bushes 5ft. in height may be helpful to some readers. We had a trench dug ready for them on arrival from the nursery. Unfortunately, though it was the middle of May, a hot, dry spell set in. As each plant was placed in position the soil was watered in, the tops sprayed and covered with tiffany. The first week this was left on and drenched with water several times daily. The next week the tiffany was removed at night, but put on during the day except on one occasion, when it rained most of the day. The tiffany was dispensed with at the end of the month, but spraying and watering when necessary was continued throughout June. Though not a drop of rain fell during the first ten days after planting, and there were drying winds, only two plants were lost out of fifty planted.

BAMBOOS.

May is the best month for the propagation by division and the transplanting of bamboos. At this time new growth is beginning—the obvious sign of active root action. An old well worn spade with a sharp edge is a useful tool to chop off pieces from the sides of healthy clumps. Sometimes if the root-stock is very woody when a large piece is lifted a mattock may be required to aid in the division. Small pieces with few roots are better potted up and placed in a warm, moist greenhouse for a few weeks.

A moderately moist loamy soil is on the whole best for bamboos. In selecting sites for planting, choose positions sheltered from the north and east. In wind-swept areas bamboos are an eyesore rather than objects of beauty for a good part of the year.

Six of the best hardy bamboos are Arundinarias fastuosa, nitida and japonica, Phyllostachys nigra, viridi-glaucescens and Henonis.

MAGNOLIAS.

Having thick and somewhat fleshy roots, great care is necessary in the planting and transplanting of magnolias. September and May are the best months for moving. It does not matter if the bushes are in flower at the present time, root growth is active and damage or loss of roots should be soon made good. Magnolias thrive best in a warm, deep, well drained loamy soil, mixing in plenty of leaf-mould and peat when planting.

A. OSBORN.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. 2.

SOME NATIVE GEMS FOR THE ROCK GARDEN

WHILE we have to go abroad for the majority of our alpine treasures, our native islands still give us some plants which are comparable to any collected on Dolomitic or Pyrenean heights, and most of them can be readily naturalised in our gardens.

Arenaria gothica, although probably originally introduced into this country from Norway, has lived with us long enough to be included in our flora. In several northern localities this little rarity is found in thriving colonies, forming tiny hummocks of sharp-pointed green leaves. The flowers are produced fairly freely in June and July, being white and star-shaped on short stems. It is not at all easy to cultivate, so far I have succeeded best with it under pure scree treatment, but having heard that it grows with extra vigour on waste heaps from deserted lead mines, I am now trying it with lead cut up and mixed in the soil, but cannot yet say whether this somewhat drastic treatment will be successful.

Another choice arenaria, a native of Yorkshire, is A. verna, which is admirable for planting in combination with that other well known native, Gentiana verna, its rather dull green tuffets of growth forming a splendid foil for the vivid blue of the gentian, and the dainty white flowers on fairy-like stems are exceedingly pretty in themselves.

Then there are all the tiny forms of the willow, every one worthy of a place in any rock garden or even alpine house. I need not describe them all, but let it suffice to say that Salix repens, S. Lapponum, S. Myrsinites, S. herbacea and S. reticulata are the best of them, and all creep and cling to the rock in a most charming manner.

Gentiana verna is almost too well known to need description, but no one sees its starry flowers of intense blue without wishing to grow and cherish it in his own garden. It thrives very happily indeed when grown in a mixture of one-third each limestone chippings, leafmould and sand. As a substitute for the leafmould, coconut fibre can be used with perfect success.

A really charming little plant is the Bird's Eye primrose (Primula farinosa), which grows by the million in the Yorkshire dales. In the spring when the ground is covered with a sheet of the small lilac flowers with golden eyes, on 3in. stems, it is a sight well worth seeing, and can, on a smaller scale, be easily reproduced at home, for it transplants with perfect composure into a cool, moist spot in the garden.

A much rarer primula is P. scotica, found only in this country along the sea coast in parts of Scotland. It is like a much fatter and smaller edition of P. farinosa, with mealier stems, and considerably darker flowers. It grows only about 2ins. high and is rather apt to flower itself to death, but can be raised readily from seed.

A real little miff, which is exceedingly difficult to cultivate at all, is Azalea procumbens. It is a minute azalea, only 2ins. high, and becomes a sheet of pink in the summer, when the flowers appear, but it only does this in the native state, for it seems to resent bitterly any interference with its woody rootstock, and unless small seedlings can be procured, it is hopeless to try to establish it, and even if established it seldom flowers in gardens.

THE GRACEFUL PASQUE FLOWER, ANEMONE PULSATILLA.

A native which is very rare indeed is Sagina Boydii. It is a plant which, while not strikingly beautiful, still attracts one by its neat and tidy habit. Its flowers, which possess no petals at all, are quite inconspicuous and they are not missed when one sees the tight growing tussocks of glossy green leaves. The plant is quite easy to grow under scree treatment—when it can be got at all, for it is very seldom offered. I have a few small plants which are doing very well, but it is very slow to increase.

One of the most beautiful of all our plants is the pasque flower or Anemone Pulsatilla, which grows profusely on a few isolated hillocks in Hertfordshire. It is entirely distinct from the large Continental form so often seen in our gardens, which forms clumps a foot or more in height with huge downy flower heads; this native form rarely exceeds 4ins. or 5ins. The flowers are of the most intense deep purple, in shape like a very wide open crocus flower.

The local name for the plant is Danesblood, as it is only supposed to grow where Danish blood has been spilt. It was a sight I shall never forget when I first came upon a lonely hillside glowing with wide purple stars; seed germinates freely and it does well in cultivation.

Cornish moneywort or Sibthorpia europæa is a nice little thing for a shady corner among ferns; it is more interesting than beautiful, but well worthy of a place in the garden. Another plant for cool shade is Wahlenbergia hederacea; this is really pretty and has a fairly wide

LYCHNIS ALPINA, OF NEAT AND COMPACT HABIT.

Digitized by Google

distribution in semi-boggy positions. I have found it on the Sussex Downs growing among Drosera rotundifolia, our native flytrap. Flowering in early summer it produces pale blue star-shaped fairy bells, studded along a thin trailing growth of ivy-shaped leaves; the plant has a delicate beauty all its own. A pretty biennial from Westmorland is Lychnis alpina. Unfortunately the flowers are of an undoubted shade of magenta, so the plant has to be placed with care. It forms bushlets of dark green leaves covered in their season with the rosy lilac flowers; it can readily be raised from seed and is one of the easiest plants to grow.

Although the foregoing are all I have time to enumerate at present, there are many more native plants that I hope to mention in future notes.

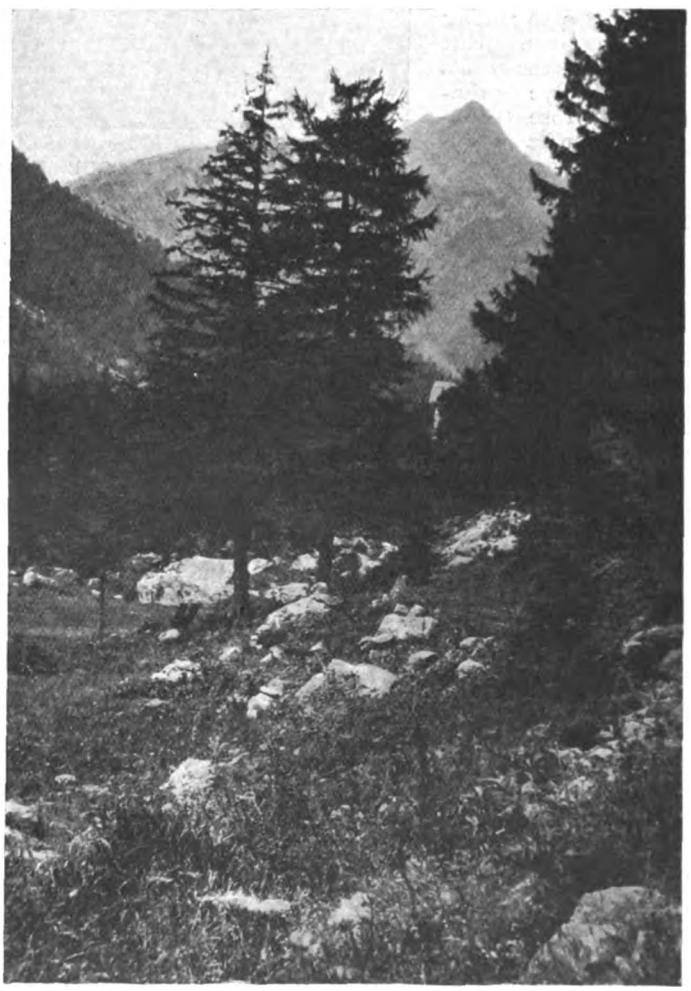
W. INGWERSEN, JUNR.

PLANT HOLIDAYS—II

BY H. STUART THOMPSON.

FROM S. Dalmazzo the long walk up the Val Miniera to the west is the most attractive to the alpine plant hunter. The Musk orchis and Listera cordata grow in mossy banks near the entrance to the valley. Aquilegia Reuteri, Geranium macrorrhizum, Digitalis media and Lamium longiflorum could not be missed, so attractive are their flowers. The rare Phyteuma Balbisii takes more finding, and happily is difficult to eradicate. Above the fork in the valley where the mines are, the north branch is known as Val Casterino. Still higher many ordinary alpine plants luxuriate, and the blossoms of Nigritella are almost invariably of a beautiful rose colour. Of primulas there are marginata, latifolia, intricata and suaveolens (the southern form of cowslip); and Orchis speciosa and sambucina, both yellow and purple, are abundant. Fortunate were the guests who ever had the privilege of staying in the summer house of the late Clarence Bicknell, which he built high up in Val Casterino. In some of the wildest regions above the valley are enormous areas of ancient rock drawings and inscriptions, which have been much written about by Bicknell and other antiquaries.

The wealth of flowers on some of those alpine slopes is beyond description. Here the ground is white with Ranunculus pyrenæus, numbers of the flowers being more or less double. There, interspersed with blue and white crocuses, are masses of handsome dwarf tulips (T. australis var. alpestris), whose yellow segments are deeply tinged with red. Only less abundant than the tulips are the spotted purple-brown bells of Fritillaria Burnati, while on an adjoining slope are thousands of the large nodding blossoms of the yellow F. Moggridgei, with here and there the purple species growing with it. To get to these higher slopes, collect plants and return to S. Dalmazzo in one day would be almost impossible. Night accommodation of some sort high up in the valley would be necessary. There is probably still nothing but a rough mule path up the Val Casterino. In other directions about Tenda such good saxifrages as S. pedemontana, S. retusa, S. diapensoides, S. florulenta, S. cochlearis, S. lingulata and S. lantoscana, can I hope still be found in greater or less profusion.



THE HOME OF MANY PLANTS TO BE FOUND IN OUR ROCK GARDENS.

The little town of Tenda, with its crumbling castle is romantically situated two and a half miles above San Dalmazzo, but it is not so convenient a place at which to stay. If the region is visited from the Mediterranean it can be reached either from Nice or Ventimiglia, whence the drive up the long Roya valley is shorter, and the main Tenda road is joined at Breil. This drive is full of interest. Of course any of these southern hill resorts might be combined with a visit to the famous Hanbury Gardens at Mortola.

It would be easy to take the Tenda district before a visit, *via* Turin and Susa, to Mont Cenis, one of the richest areas for alpine plants. But so much has been written since 1908 about Mont Cenis and its flora, that I propose to say nothing here, except that the hotel accommodation is none too good, and since the advent of motor cars it is frequently noisy, especially on Sundays.

The Col du Galibier, leading from S. Michel de Maurienne in the Arc valley and the railway near Modane to the mountains of Dauphiné and Lautaret, has a very large number of high alpines, and the district might advantageously follow a visit to Mont Cenis. But though the Lautaret pastures are renowned for the beauty and luxuriance of their flowers, and notwithstanding a nice alpine garden, the big hotel is, in the season, the rendezvous of a fashionable cosmopolitan crowd, so that I am not alone in having found quieter and less expensive quarters at one of the two hotels at La Grave, 5,000ft., a few miles down the road which leads to Grenoble. La Grave is quite a good place at which to spend a week or more, and the views thence of the Meije are very striking. Moreover, if good walkers want to do one of the easiest glacier ascents of 11,600ft. in the Alps, they can get a guide to take them up to the Col de la Lauze. The lower slopes are full of interest to the botanist. So are those of the Aiguille de Goléon. La Bérarde, with good hotel, is another desirable centre in the Dauphiny mountains.

Therefore, if opportunity occurs, it is certainly worth while to leave the train at St. Michel and walk *via* Valloire over the Col du Galibier, which after the Stelvio has the highest carriage road in Europe. When I took that walk in 1907 it struck me that the large and well built village of Valloire might afford an attractive place at which to stay, and it is the prosperous looking centre of an interesting district.

Val d'Isère (6,000ft.) north of the Col d'Iseran and accessible from Mont Cenis, Lanslebourg or Modane railway station, is a delightfully situated little village, with two comfortable

Digitized by Google

hotels, which I often wish circumstances had allowed me to stay at for more than one night. Alpine guides are procurable there, if wanted, for any of the longer expeditions.

Cogne, 5,oooft., in the Graian Alps, is a particularly delightful place both for flowers and big mountain expeditions. It has had its praises blown as a climbing centre and as a paradise of flowers by Mr. George Yeld, Editor of *The Alpine Journal*, and the whole district is authentically described in his "Scrambles in the Eastern Graians, 1878-1897." The valley of Cogne is easily approached by carriage road either from Aosta or Courmayeur, and a visit to the latter resort might well be done on the same tour.

Space precludes more than mere mention of a few of the best centres for alpine plants in Switzerland. Moreover, they are known to so many. In central Switzerland perhaps Engelberg is one of the richest and most frequently visited. The limestone sub-alpine woods are remarkable for the large number of orchises, including Cypripedium Calceolus; but it behoves collectors to remember the increasing rarity of this European orchid. One of the best walks from Engelberg is up to the Trübsee and over the Joch Pass.

The Valais is the Swiss Canton with the richest flora, of at least 1,785 vascular plants, though the Canton du Vaud (with Ormont-dessus as a good centre) comes a good second, and Berne has about a hundred fewer species according to Jaccard. In the Valais all the valleys south of the Rhone are good, and the nearer one gets to the Italian frontier the richer the flora. I have walked up or down every one of these lateral valleys, from Binnenthal in the east to Val d'Illiez in the west, and each possesses some special feature. But perhaps the best from our point of view are Binn, Saas, Zermatt Valley, Val d'Anniviers (Zinal, 5,5ooft.), Val de Bagnes (Fionnay is a good centre), and Val d'Entremont, where the place to stay is Bourg St. Pierre on the road to the great St. Bernard and Aosta and close to the charming Jardin de la Linnæa.

The Valley of Chamonix in Haute Savoie is comparatively disappointing botanically, and in these days Chamonix in July or August is a place to avoid. There are plenty of hotels at or above Argentière or on the Swiss frontier, which can be visited in comfort, and whence Mont Blanc and her satellites can be viewed in peace. But the Italian sides of Mont Blanc are more floristic and far less frequented, because much less accessible. Courmayeur (Hôtel du Mont Blanc) is a delightful centre at just 4,oooft. So is the higher station of Breuil above Val Tournanche on the Italian side of the Matterhorn and Théodule Pass. The village of Valtournanche (5,oooft.), has several small hotels and ample first-rate guides; but I strongly recommend the higher solitary Hôtel du Mont Cervin at nearly 7,oooft. It is a large and excellent Italian hostelry, and in the midst of an immense wealth of alpine flowers.

ST. MAURICE, A GATEWAY TO SEVERAL OF THE LATERAL VALLEYS OF CANTON VALAIS IN SWITZERLAND.

In Canton Tessin, Piora above Airolo has of recent years become a favourite resort for lovers of the picturesque and of flowers. It was one of Canon Ellacombe's delights to go there late in life. But there are so many good centres, and already in this sketch we have exceeded our allotted space, and cannot refer to the Engadine or any district farther east.

Ball's "Alpine Guide," both old and new editions, gives numerous short lists of interesting plants for many localities. This is much the best guide to the Alps in any language, and no one in these Islands at least knew the Alps and their flora so well as John Ball. Longer lists of plants under the various districts can be found in Vol. VII of Gaudin's "Flora Helvetica," 1833. In fact the whole of that volume of 660 pages is devoted to such lists, and the places are arranged in alphabetical order.

The photograph on this page is by permission of the Swiss Federal Railways.

AN EIGHTEENTH CENTURY NURSERYMAN

AT the beginning of the eighteenth century the East End of London was still an important centre for nursery gardening, although the smoke from the "sea-coal" was already beginning to intefere with the business. At Hoxton there were three large nurseries and a wine-producing vineyard that was probably the last of its kind in England. One of the nurseries was owned by John Cowell, who attracted a good deal of attention in 1729 by flowering the American aloe (Agave americana) and the torch-thistle (Cereus grandiflorus). In the same year he broadcast his success in a small booklet describing the two plants and also the Glastonbury thorn, another of his specialities. This booklet he re-issued, with much additional matter, in 1730, under the title of "The Curious and Profitable Gardiner," and a second edition of it was published in 1732 with the title changed to "The Curious Fruit and Flower Gardiner," by Richard Chandler "at the Flower-de-Luce without Temple Bar."

This last book gives an interesting picture of a phase of English gardening that is a little overshadowed for us now by the activities of the great landscape gardeners who had things so nearly their own way during the eighteenth century. The stovehouse had just been invented, after some preliminary experiments with heated walls and orange houses warmed with open fires, and now, for the first time the cultivation of tropical plants was a practical possibility.

The new fruits that were being introduced from the Colonies by the wealthy "Nabobs" interested Cowell even more than the flowers, and he gives an enthusiastic account of "The Bonana or Plaintain of Surinam; with others the most extraordinary and Admirable Fruits." The others were the pineapple, guava, mango, papaw and shaddock; and it comes with a little shock of surprise to find that these, still rare, exotic plants were grown for the sake of their fruit by private individuals at the beginning of the eighteenth century.

After describing the new fruits and their culture, the author gives a chapter to a method of naming varieties of garden plants that was in use among "the very curious Flowerists abroad." The initial letter of the name indicated the colour of the flowers; if it had two colours a double name was given and the predominating colour shown by the initial of the first word. So that a white flower marked with crimson might be called "William the Conqueror" or the "Wonder of Constantinople."

The next chapter deals with the management of the tulip. a flower that was still very popular, although the full force of the tulip mania was already past. Directions are given for inducing the flowers to break, but the author does not recommend them very strongly, seeming to incline to the view of "the learned philosophers" that variegation "proceeded from some weakness or distemper," while the methods quoted seem designed to stimulate, and the impatient are told to: "Take the Plaister of old Walls, . . . powder it fine and mix it with drift Sand, or such Sand as is sharp, and found on the Sea-shore: to this add of the Water that runs from a Dung-hill or Jakes, that one may have an equal quantity of each, . . . and put it over the surface of your bed a little before you plant your breeding or plain Tulips, and 'twill make them break into fine Stripes to a Wonder, as is related to me by a Gentleman of Great Honour, who has proved it, as he observed, for five or six Years." Another method, "less noisome than the first," dictated a top-dressing of slaked lime and pigeons' dung in equal parts, and it seems to have been generally believed that lime favoured "breaking," for the soil in the famous garden near Brussels where tulips broke so freely was said to consist chiefly of mortar rubble.

There follows a short memorandum on growing roses. There were not yet many kinds in cultivation, for the great influx of new varieties from the Continent and the East was to come some sixty years later. Bradley, writing in 1719, says that sixteen varieties were grown by "that curious and incomparable Patroness of Botany," the Duchess of Beaufort, in her garden at Badminton, and he seems to consider it a large number, though Parkinson, perhaps making finer distinctions, had enumerated about thirty. Cowell, excluding all single and semi-double roses except the Austrian briar, gives the following fourteen as the chief sorts: the damask, the Provence ("the red and the common Sort"), the two sorts of striped roses, York and Lancaster, and Rosamundi; the white rose, the velvet rose, the carnation rose, the musk rose, the Holland's or the Belgick rose, the monthly rose, the Austrian and the double yellow.

Of this last we are told that it is "hard to blow; and some curious Gentlemen have attempted it without success by nailing it against a wall." This is the old sulphur cabbage rose (R. hemisphærica) that was introduced from Constantinople by Celsius; but even the most curious gentlemen seem to have given up the attempt to grow it in our climate. The "Monthly Rose" was probably a damask, for the China rose, that was to give rise to the monthly roses that we now know, had not yet been introduced. Rosamundi (now also known as Cottage Maid) and York and Lancaster are still grown, though one sometimes passes for the other, yet they are distinctly different as they are figured in Miss Lawrence's book of roses (1799), where Rosamundi is shown boldly striped, about equally deep pink and white, while York and Lancaster has some petals pure white and others finely pencilled with carmine; the pink and white petals are usually grouped together on either side of the flower, so that the general effect suggests the unfinished work of the gardeners in "Alice in Wonderland." The "Velvet Rose" was apparently a dark red Provence, the "Belgick Rose" a red damask, and the "Carnation Rose" (Rosa incarnata) a small pink.

The book ends with a description of the Glastonbury Thorn and a long account of its introduction by Joseph of Arimathea, whose staff blossomed miraculously one Christmas Day as he was preaching to the unconverted on the Isle of Avalon. The parent plant from which Cowell derived his stock was still alive at this time at Glastonbury, and was an object of pilgrimage at Christmastide, when, he says, it never failed to flower. It is still seen in a few gardens, where it is valued for its habit of flowering at intervals through the winter as well as in May, though there seems to be nothing to support its claim to an Eastern origin and the botanists find that, except for its double flowering season, it is identical with the common hawthorn.

Cowell's career seems to have ended with the flowering of the aloe, for he is referred to in 1730 as "late of Hoxton," and, although it is not clear whether he had died or only left the neighbourhood, that is the last we hear of this "excellent Florist and polite Gentleman, famous for Gardening." F. A. H.

NOTES FROM NEW JERSEY

I CAN substantiate what Charles Leray says (December 6th, 1924, issue, page 821) of the double Hydrangea Domotoi. It has been listed by Henry A. Dreer for two or three years, but so far has not been taken up to any extent by the florists. When visiting the New Jersey State Experimental Station two years ago to see the results of the colour control experiments on hydrangeas, H. Domotoi was colouring up nicely and was decidedly double. I have seen no large specimens of this variety, however. Incidentally, while hydrangeas, including some of the new hybrids, are largely grown by the florists for early spring trade, no one appears to produce the giant heads on small plants that are the rule in the London market. Here, the plants are grown with several heads, often overpotted and not notably good, except the larger specimens, 18ins. and over across, these carrying six or more trusses. Trophee is fast becoming the popular dark pink, but ordinarily most growers have a greater percentage of blues than pinks. Trophee shows less tendency to come blue than the older sorts. Since the New Jersey experiments proved that it is possible to control the colour, however, growers are likely to produce a greater percentage of pink shades. It is all a a question of soil alkalinity and acidity; the latter means blue graduating down to pastel mauves. When pink shades are wanted lime brings about the desired results. An overdose of lime, however causes chlorosis. Up to the present,

Digitized by Google

Chas. H. Connors, who carried out the experiments, has not issued a complete report, but when lecturing before the New York Florists' Club last year he provided sufficient data to enable growers to achieve what they desired.

The reference in the same issue to the Chinquapin, the native dwarf chestnut, prompts me to mention that the late De Van Flut made a number of crosses with the chinquapin and other species of chestnuts with a view to developing a chestnut that is proof against the blight. Throughout the northern section of the United States the large or true American chestnut, C. dentata, has been practically wiped out by a mysterious disease supposedly introduced from the Orient in 1904. No cure or preventive of this disease has ever been found, and only in rare instances, I believe, can specimens be found in this section. The Department of Agriculture, I believe, has a number of chinquapin hybrids, mostly crossed with the Japanese chestnut.

With reference to the question of circumventing moles, I am fain to admit that the English mole is more easy to trap than his American cousin. The American mole does not throw heaps periodically, as does the English mole; he runs just under the surface when hunting, heaving all the time, so that it is not just a matter of burrowing beneath one's onion, sweet peas or grass patch, but the actual lifting of the surface throughout the course of operations. At no time is the lift more than 1in. or 2ins., but on one trip a mole can cover many yards. It is practically useless to set traps on newly made runs, as only rarely does the mole use the same track. If he does, he is too tricky to go through a trap. There are several forms of traps in use here, but they are more or less a joke. Some have formidable spikes which are supposed to spear the mole, but I never have caught one with such a trap. I have now an English trap, but all I learned about catching moles in England is useless here. I have caught one in the trap in four years. I have set it in a main run and pegged it down, but Mr. Mole goes round or beneath it. I have tried castor beans and arsenated raisins, which western growers use with success, but of no avail, so it is now my intention to use the new calcium cyanide, which is being used in enormous quantities in the south and west for destroying moles, ground hogs, land crabs, ground squirrels, voles and similar pests. Calcium cyanide, an American discovery, does away with the use of acid as required for sodium cyanide. It is in the form of powder and has but to be poured into the runs at intervals. It is also being used for greenhouses, for while generating the deadly hydrocyanic gas, it is slower, therefore less dangerous. It has but to be sprinkled on the paths about ½ oz. to every 1,000 cubic feet, and the atmospheric moisture does the rest. Laid down at night, the house can be closed and left until morning, by which time the gas has dissipated, leaving nothing but free nitrogen and lime. Calcium cyanide is made by fusing sodium chloride with cyanamid, which latter is a nitrogeneous fertiliser made by fusing liquid air with calcium carbide.

T. A. WESTON.

TWO UNCOMMON PLANTS

ERICA STRICTA.

THE Corsican heath is no rare plant in the southern parts of Italy and of Spain, but I have never seen it in the open air in the gardens of central Europe. Even in England it seems to be rarely met with. The finest plants I came across were in the garden of the late Mr. Allard at La Maulévrie, near Angers, France. There I found years ago a fine collection of ericaceous plants, and among them the well flowering bushes of E. stricta, of which I took the accompanying photograph.

The bright pink flowers of the Corsican heath contrast well with the dark green foliage. They open rather late in summer, and for this reason the species is an even more desirable plant for the heath garden. It has rather stiff, rigid branches, and the leaves are arranged in fours. Whether there are some varieties with white or darker reddish flowers I do not know, at least there is none mentioned in the dendrological books at my disposal.

Behind the flowering plant of E. stricta in the picture there is a somewhat larger bush of the common tree heath that opens its fragrant flowers in spring, and it is a common feature of the landscape in the Mediterranean.

TAXODIUM DISTICHUM.

The North American bald cypress, Taxodium distichum, was introduced to Europe about 1640. According to Britton, in its native home it is confined to the coastal region from Southern Delaware to Florida, westward, near the Gulf, to Texas, and up the Mississippi Valley to Missouri and Indiana. It often forms great forests in swamps and along rivers and streams. In England as well as on the Continent the bald cypress or deciduous cypress, as it is often called, forms one of the most striking features in our parks. As its name indicates all its leaves and the small lateral shoots fall away in autumn. They form a fine feathery foliage which is of the palest and tenderest green in May, while it becomes beautifully reddish brown and somewhat shining in October. In spring as in fall the trees attract everybody's attention, and they have, as Bean rightly remarks, nothing similar to them in the whole range of hardy trees. They develop straight trunks, tapering to the top and buttressed at the base almost like those of sequoia. Besides, except in too dry a place, T. distichum has the peculiarity to form the so-called knees, upright projections from the roots, which often appear in great number. An illustration was given of this tree in THE GARDEN, March 14th, page 142. After all, this interesting and hardy conifer ought to be planted wherever a suitable place can be given to it.

ERICA STRICTA WREATHED IN ITS BRIGHT PINK BLOSSOMS.

Besides T. distichum, two more species are known of the genus. One of them, T. mucronatum, is a native of north-eastern Mexico, and I have never met with it on the Continent. It is closely related to distichum. Even the third species is often regarded as only a variety of it. Its correct name is T. adscendens, T. imbricarium being a synonym. The leaves of all its twigs are closely appressed and spirally arranged, not two-ranked as in the deciduous twigs of distichum. A pendulous form of adscendens is sometimes seen in our gardens under the name of Glyptostrobus pendulus, but the true glyptostrobus is a Chinese plant often called T. heterophyllum and rather distinct from the American species. CAMILLO SCHNEIDER.

THE SPRING ROSE SHOW

MANY members of the National Rose Society travelled quite long distances to attend the "Feast of Roses" at the Royal Horticultural Society's Hall, Westminster, on April 24th last, and, we imagine, all felt themselves amply repaid for their journeys. There might, perhaps, have been a few more blooms in the hall, but the quality was surpassingly great, and this was not confined to the exhibits of the great trade growers, who have long ranges of glass houses at their disposal; for in some instances the amateurs more than held their own in the friendly rivalry.

There was no finer collection of exhibition roses in the Show than the twelve which bloom in the amateurs' section. The premier nurserymen's bloom, by the way, was a wonderful and deliciously fragrant Marechal Niel, shown by Mr. A. R. Goodwin.

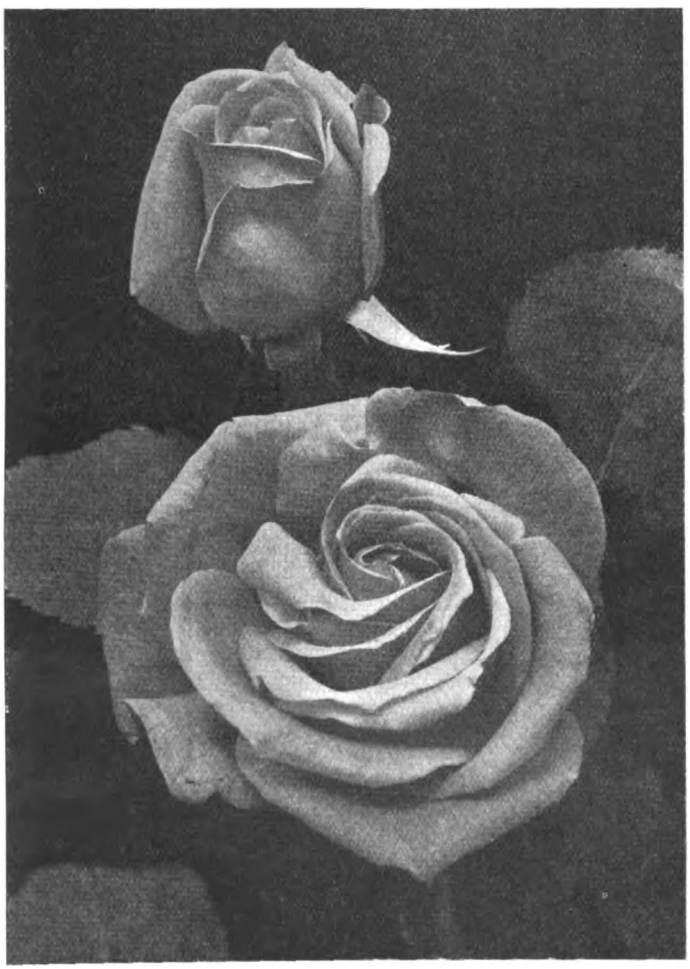
Although it was in a class open only to growers of not more than thirty pot plants the first prize six which Mr. C. Chambers of Harrow showed were of particularly good quality.

A basket of Mrs. Amy Hammond found many admirers, and it won the first prize for Mr. G. A. Hammond; while Mr. J. N. Hart, Potters Bar, was similarly successful with a basket of mixed varieties.

The great outstanding feature of the nurserymen's section was undoubtedly the magnificent group of roses so well arranged by Mr. Elisha J. Hicks, and this was of such superb quality that the judges awarded a silver-gilt medal in addition to the first prize. There were masses of bloom of all types. At the back such cluster-flowered varieties as Ellen Poulsen, Excelsa, Coral Cluster and Orleans were delightful, while high quality was provided by the vases of Marechal Niel, Chas. E. Shea, Ophelia, Los Angeles and similar varieties, placed on a lower level. A smaller group won the second prize for Mr. George Prince, and this included Lady Hillingdon, Pax, Augustus Hartmann, Souvenir de Claudius Pernet, Victoria and Charles E. Shea of high quality. Messrs. B. R. Cant and Sons and Mr. Walter Easlea also set up admirable groups of roses.

The only circular group on a floor space was exhibited by Messrs. Chaplin Brothers. On a raised centre they showed tall pillars of Godiva, American Pillar, Lady Gay and similar sorts; while below standards of Padre, Souvenir de Claudius Pernet and Golden Emblem, they had delightful dwarfs of Mme. E. Herriot, Maud, Ophelia, Golden Emblem, Mrs. Henry Bowles and Mrs. Herbert Walsh. Messrs. Chaplin Brothers were also the only exhibitors of six pillar roses.

Polyanthus roses in pots made a very pretty show. Mr. Pemberton's first prize group contained most flower, especially on Suzanne Turbat, Edith Cavell, Juliana and Jessie. Among the varieties shown by Messrs. William Cutbush and Sons we noted Salmon Queen, Chatillon Rose, Rudolph Kluis and Ellen Poulsen.



ROSE "TEMPLAR," WHICH RECEIVED A GOLD MEDAL.

'RED EXPLORER.' A NEW CLIMBING POLYANTHA ROSE.

won the first prize for Mr. G. A. Hammond of Burgess Hill. Mrs. Henry Morse, Mrs. Campbell Hall, Augustus Hartmann and Mrs. Foley Hobbs, for example, were excellent. In the class for six blooms of any one variety, Mr. Hammond also won the first prize, showing well nigh perfect specimens of Mrs. Foley Hobbs, and Mr. S. F. Jackson was a good second with the same variety.

A great many amateurs tempted fortune with six blooms of exhibition roses, and here the pride of place was gained by Mr. H. Oppenheimer, Caterham Valley, who won first place largely on account of the beautiful colouring of his specimens, which included Mrs. C. Russell, Mrs. R. D. McClure and W. E. Wallace. Mr. S. F. Jackson, who had to be content with second place, no doubt felt reconciled with the silver-gilt medal which his well nigh perfect bloom of Mrs. C. Lamplough won as being the premier

Exhibition roses in the trade classes were very good, and in their first-prize twenty-four Messrs. B. R. Cant and Sons showed considerable skill in colour arrangements. Their best sorts were Rev. F. Page Roberts, John Davison, Glory of Steinforth, Padre, and Margaret M. Wylie. Mr. Hicks was second, and he included Candeur Lyonnaise, Mrs. Foley Hobbs, Frau Karl Druschki and America of merit.

The class for twelve blooms of any one variety was one of the best in the Show. Mr. A. T. Goodwin was first with Marechal Niel, of perfect form and colour with most delicious fragrance, and one of his blooms won the silver-gilt medal as being the best in the trade classes. Mr. Hicks was second with Clovelly, of beautiful pink colouring; and Messrs. B. R. Cant and Sons were third with lovely Constance Cassoon.

Digitized by Google

The baskets of roses were all highly decorative. The best two were of Lady Hillingdon and Mrs. Henry Stevens, shown by Mr. Hicks; while Mr. Goodwin was second with Marechal Niel and Frau Karl Druschki, and he was first with a wonderful basket of Marechal Niel in the class for one basket, where Messrs. Alex. Dickson and Sons were second with glowing blooms of Fred. J. Harrison and a crimson seedling.

The amateurs quite held their own in point of quality, though they could not show roses in such generous quantities as the trade growers. There was nothing finer than the twelve exhibition roses which Mr. G. A. Hammond showed. His specimens of Mrs. Amy Hammond, Mrs. Foley Hobbs, Mrs. C. Hall, Mrs. Henry Morse and William Shean were superb, as also were his six blooms of Mrs. Foley Hobbs in the class for any one variety; while Mr. S. F. Jackson was a good second with the same sort; and, although Mr. Jackson came second to Mr. H. Oppenheimer with six blooms in not less than three varieties, he included, in a magnificent Mrs. C. Lamplough, the medal bloom of the amateurs' classes. Mr. Oppenheimer's collection had more colour and included W. E. Wallace, Mrs. R. D. McClure and Mrs. C. Russell.

The two groups of roses in this section were also highly creditable. Mr. Hammond, who won the first prize, had a charming basket of Ophelia surrounded by vases of Muriel Wilson, Rev. F. Page Roberts, Mrs. E. Mawley and William Shean of fine quality. Mr. H. R. Darlington was second. Although Mr. S. F. Jackson was alone, he showed fascinating vases of mixed blooms in the class for six vases. Mr. Chalmers won the first prize in the class for growers of fewer than thirty pot roses.

The decorations of roses reached a high standard of artistic merit, and it was interesting to note that, apparently simultaneously, several ladies realised the value of sprays of purple Japanese maples for associating with their roses in the dinner-table decorations. Mrs. Courtney Page, who had this foliage and a few discreet fronds of maidenhair fern with Mme. Butterfly roses, arranged a most charming table and was deservedly first. Mrs. A. D. Ruff was second with lovely Melody roses; Mrs. Oakley Fisher, who associated maple sprays with Roselandia, was third; and Mrs. A. Robinson was fourth. In the trade class Mrs. May was first with Mme. Butterfly; Mrs. Tisdall was second with a glowing table of Richmond; and Mrs. A. R. Bide was third with Mme. Butterfly and purple maple foliage.

The bowls and vases were also most attractive. Mrs. Courtney Page, who mixed Mme. Butterfly and Ophelia, was first with a vase and second with a bowl where Mrs. Charlton was first with Mme. Butterfly. In the open class Mrs. A. R. Bide had a fine bowl of Mrs. G. Beckwith; Mrs. Tisdale was second.

A few exhibits of miscellaneous plants added interest to the Show, but of more special moment to rose lovers were the "sundries," such as the well known "Abol" preparations for combating insect and fungoid pests, and their fertiliser of excellent analysis, together with the Abol syringes. Messrs. William Cooper and Nephews, Limited, also showed insecticides of tried value and made an especial feature of their White Fly Fumigant, which is said to be very successful with this destructive and annoying pest. Katakilla—the name is well descriptive of the preparation—was attractively shown by Messrs. McDougall and Robertson, who also have a special hand-sprayer for distributing it to the best effect. Their weed killer, winter wash and the McDougall Fumer are all well known aids to successful rose-growing. Nowadays all the materials and apparatus supplied by these firms are most necessary to successful rose cultivation.

NEW ROSES.

ANGELE PERNET.—A vigorous Pernetiana seedling, well supplied with large shining leaves, good stems, and bearing medium-sized blooms of old gold colour flushed with peach pink. The flowers are sweetly scented and are of good shape in all stages. Certificate of merit. Shown by Messrs. G. Beckwith and Son.

BARBARA ROBINSON.—A useful hybrid tea variety which produces long, pointed buds of pale yellow colour which becomes creamy yellow when the flowers are fully expanded. Shown by Messrs. Alex. Dickson and Sons.

DAME EDITH HELEN.—This is a showy, rich pink hybrid tea rose, with well formed blooms borne on long, stout stems. The broad, substantial petals curl back prettily, making it a good variety both for exhibition and for the garden. Shown by Messrs. Alex. Dickson and Sons.

HYPATIA.—A vigorous bedding rose of medium size. The buds are pointed and the mature flowers are of salmon pink colour. Shown by Messrs. Bees, Limited.

JOAN HOWARTH.—This delicately beautiful rose has already received a certificate of merit, and, although it was larger and better than before, it did not receive the higher award. It is a fully double rose, made up of large substantial petals of deep flesh pink colour, and is recommended for the garden and for exhibition. Shown by Messrs. Bees, Limited.

GWYNNE CARR.—Another variety which has previously received a certificate. Although the blooms were very attractive, the foliage was not good, but we suspect this defect is not inherent in the variety and is only temporary. Shown by Messrs. Alex. Dickson and Sons.

LADY MARGARET STEWART.—A very vigorous hybrid tea rose which bears enormous solid flowers of good shape but rather gross appearance. In general the flowers are white, but they are tinted with yellow and with buff. They are slightly fragrant and the foliage is very good. Certificate of merit. Shown by Messrs. Alex. Dickson and Sons.

MAUD E. GLADSTONE.—An attractive polyantha variety nearly 2ft. high. It is free-flowering and bears large trusses of double flowers of old-fashioned shape and pretty pink colour. The buds are coloured deep coral pink. This should be a very useful variety for garden decoration. Shown by Messrs. Bees, Limited.

ROSELANDIA.—This valuable yellow hybrid tea rose received an award of merit at the R.H.S. meeting. Certificate of merit. Shown by Mr. Walter Stevens.

SENSATION.—An exceedingly sweetly scented hybrid tea rose of deep velvety maroon colour lightened at the edges of the petals by crimson. It is beautiful in the bud state and of goblet shape when mature. The stems are practically spineless and the foliage is good. Besides being a good garden rose it is recommended for forcing. Shown by Messrs. G. Beckwith and Son.

SALTAIRE.—Another deliciously fragrant dark rose, but, as shown, makes excessive foliage. The fully double hybrid tea blooms are of medium size and deep velvety crimson colour, which almost suggests what might be termed a deep, burnt cardinal. Certificate of merit. Shown by Messrs. Alex. Dickson and Sons.

TEMPLAR.—Still another dark hybrid tea rose possessing in a marked degree that precious gift of rich fragrance. Allied to this most desirable quality is rich crimson colour with a fascinating sheen of maroon in the heart of the rose. The stems are practically spineless and the neat foliage is a rich dark green. It is recommended for "garden and bedding"; the goblet-shaped blooms have not sufficiently good foliage for the exhibition board. Gold medal. Shown by Messrs. G. Beckwith and Son.

WHITE ENSIGN.—This is decidedly the best new rose of its type for many years past. The perfectly shaped, medium-sized flowers are borne on long graceful stems which carry neat dark green foliage. The plants are of free branching habit and the variety is recommended for forcing purposes as well as for the garden. At a little distance the blooms appear to be pure white, but a closer inspection reveals a fascinating creamy centre. Certificate of merit. Shown by Messrs. S. McGredy and Son.

WILLIAM BOWYER.—Half a dozen dwarf plants, unaccompanied by the customary vase of cut blooms, were shown of this dwarf hybrid tea rose. The moderately fragrant, medium-sized blooms are of crimson-maroon colour. Shown by Messrs. Chaplin Brothers.

RED EXPLORER.—Presumably this fine climbing polyantha rose was shown in competition for the Cory Cup, which is not awarded until after the Autumn Show. A splendid pot plant rather over 6ft. high was shown, and this was well furnished with erect trusses of bright crimson flowers. It is said to be a sport from Edith Cavell. Shown by Messrs. Cutbush and Sons.

SYNTHYRIS RENIFORMIS.

IT is a little surprising to find how few, even among those who are really enthusiastic rock gardeners, are well acquainted with the synthyrises, which hail from north-west America, and some of which are of real grace and charm in the rock garden. Up to the present only a few species have been described, but I do not think that any but S. reniformis and S. pinnatifida are in commerce. Of the two I have not the slightest hesitation in asserting that S. reniformis is far and away the better. Alike in foliage and in flower, it is more attractive, and it is quite as easy to grow. Personally, I have never cared to trouble with S. pinnatifida, which I have seen in several places where S. reniformis was also cultivated, deeming it inferior to S. reniformis, which I prize as one of the best of alpines, but the former gained the favour of the late Mr. Farrer to some degree, although not so highly as S. reniformis, as he speaks of its "dainty plumes of blue." Its leaves, as the specific name would suggest, are finely divided. The spikes are also a little taller. S. reniformis is worth looking at even when out of bloom, with its tufts of rounded or kidney-shaped, brownish, rather leathery, prettily scalloped leaves. Its crowning beauty is, however, in April, when it comes into bloom and gives us its 4in. to 6in. spikes of violet flowers.

It belongs to the same Natural Order as the veronicas, and one observes at once the family resemblance in the flowers, though on the spike they present, as Mr. Farrer remarks, a "furry" appearance. They are most delightful, especially to those who can appreciate the smaller gems of the rock garden. In its native habitats S. reniformis grows among grass near streamlets on the slopes of the mountains near the Pacific coast, but in cultivation, although it likes a cool situation, it seems happy enough in sun or shade. Still, save under exceptional conditions, it is well to adopt the native habitats as suggestive of its requirements with us, though omitting the grass, and I prefer a cool place in the rock garden for this delightful little alpine flower. There is said to be a yellow, but undesirable synthyris called S. Bullii, but the possession of S. reniformis will enable its owner to enjoy the beauty of the most fascinating member of the family.

S. ARNOTT.

CORRESPONDENCE

HOME HYACINTH GROWING.

SIR,—The hyacinths seen in this illustration are grown by Miss A. E. Coles of Radlett, where this lady enthusiast raises these lovely flowers for the benefit of friends and any of the general public who like to call at her beautiful dwelling to see the gems. About three hundred bulbs, growing in sixty or seventy receptacles of all sorts, fill the room with their wonderful fragrance. Miss Coles takes pride, and justifiably so, in pointing out the fact that the work is all done by herself. She places soil in the bowls, etc., just taking some ordinary garden soil or compost from an old cucumber bed, and uses small stakes from the prunings of her fruit trees to support the blooms. A few varieties that struck one with their beauty were Perle Brilliant, of porcelain blue and large-sized bells, the spikes of which, when the writer saw them, were no less than from 12ins. to 15ins., while even King of the Blues, grown for a second season, were from 6ins. to 9ins. in length. Chestnut Flower, a wonderful variety, most distinct in appearance, strong growing and

A FINE COLLECTION OF HYACINTHS GROWN IN ORDINARY GARDEN SOIL.

with double bells of soft rose pink, deeper within, were thriving in large quantity, while another glorious dwarf variety that stood out against its fellows was Orange Queen, opening pink and turning to a creamy buff, and in good contrast to it was Orange Brilliant, a striking variety with orange and red tones. Some other varieties grown were Loveliness, Lady Derby, Princess Victoria, La Grandis, Electra, Distinction, Salvator and Fair Ellen.—A.

SWEET SCENTED CYCLAMENS.

SIR,—I was much interested to read Mr. C. Turner's letter on scented cyclamens in your issue for April 18th. I think it may interest your readers to know they can procure seed of these from Messrs. Sutton and Sons, who claim they have seed of "large-flowered, sweet-scented." I fear it is the present-day desire of growers to sacrifice everything for size of blooms, hence our scentless cyclamens of to-day. I for one have sown a packet of Messrs. Sutton's seed and am growing on thirty very strong young plants of which, I feel sure, I shall much enjoy the scent next winter and spring.—E. MCCREERY.

DIGGING AND TRENCHING.

SIR,—I would crave your kindness again to refer to the above very controversial subject, and in particular to the very courteous letters of "G. H. H." and "J. H.," which appeared in the issue of THE GARDEN for April 18th. Firstly, my experience with soils has extended nearly the whole gamut, including such trying subjects as sandy soil overlying gravel subsoil, and also chalk soils, and I have never yet hesitated to delve right into them in order to bring the under layers up to the surface. My idea is best summed up in the words, "If a thing is worth doing, it is worth doing well," and though the gradual process suggested by "G. H. H." may appear to many a sane gardener as a good and useful compromise, where subsoil is what may be termed "bad," yet I would assure them that it would pay better in the long run to "go the whole hog," and bring up that inferior material straight away without hesitation, though it may require a modicum of moral pluck to do so. In this act you open up the packed lower layers, afford a certain amount of drainage, and prepare a better root-run, and at the same time you bring under immediate control the poorer part of the soil and place it into a position where it can receive more direct attention with a view to its reformation as a bad character.

I would give two concrete examples of this method of trenching for this poor conditioned subsoil. The first case is when at Aldenham, during the distressful period of war, we placed every possible acre under vegetables for food purposes. One area so treated was a space of thirty acres exceptionally poor pasture land, covered with hummocks of grass, and an insect-infested space at best. The tussocks were rooted out, and for the first season, in order to give birds and frost their scope in ridding the soil of the company of wireworm, etc., it was only shallowly ploughed. The treatment was effective with regard to the pests, but I was not satisfied with the crops gained from the ground, even though the main part was under potatoes. Not disappointed though, for the return was good, but not such as I wished to get, for I had to break from my usual method. The second season, however, the ground was broken right into and the soil inverted, and then we did get the results, even though we had brought the subsoil to the top. The other instance was another piece of ground in poor fettle, and again of the London clay type. This, in order to get the results from it, was trenched by hand, and one part of it was planted with cauliflowers. The result was actually astonishing, for, despite the heavy character of the ground (and we had not been able to add much material to benefit it), the broccoli thrived so immensely that many of the heads weighed up to 12lb., some going over that weight, of the prettiest, firmest curd that any grower could wish to see.

Another point that "J. H." refers to is the effect of climate on the soil. This at the best must be a question of what, for want of a better term, is generally termed luck! It is owing to the possibility of there being no extended frosty period but in lieu thereof a probablility of heavy rains, that I advocate that heavy soils should not be trenched until late winter and early spring; for, by deferring to such time, the risk of the ground packing again through the beating effect of rains and percolating water is lessened by the shorter space of time intervening between trenching and planting. Naturally, whatever the climatic influences, the surface of the soil requires to be broken or fined down in preparation for sowing or planting. Here let me interpose a remark to "J. H." that his suggestion that much labour, even up to ten times that available to the average grower, is permissible to produce the exhibition vegetables from Aldenham, is very wide of the mark. Probably the secret of such success is organisation and the methods of oil preparation that I am now defending, for on our large areas of vegetable ground, which are admittedly on a bigger scale than, say, the average garden, I do not think the man power per acre would work out so much as is often employed on quite tiny patches of ground. Certainly it is not above the average, for the preliminary work, along proper lines, helps enormously in the later stages.

Just a last word or two on the matter. Even if you who read these notes only have quite a small garden, I would advocate the trenching method, better trench half the garden than only scratch the whole surface of it over. You will then get the results, though it may mean a certain amount of more strenuous labour at the start. Further, should the results not mature the first season, see if you can discover where you have failed, and repeat the process of trenching the next season undismayed, for in my opinion you are on the right road to success. Work in all the vegetable refuse material you can, and the remains of the garden rubbish fire. All this sort of thing helps, so trench! trench!! trench!!!—EDWIN BECKETT.

ONIONS AND RATS.

SIR,—The enclosed will, I think, interest some of your readers. It is an extract from a letter received some time since from Devonshire. I understand that rats never eat onions, and, presumably, shallots. If so, why on earth do they hoard them? Perhaps someone can explain. "The following may amuse you. On or about the shortest day I planted my shallot bed. It took 66 sets (my own special sort and none left for replacements). Within a week every set had gone bar one. A month later I found two rat-holes near my garden. I dug them out—recovered the 65 sets exactly and replanted them, and now they look like giving the usual crop."—CHARLES S. ROBINSON.

GARDENING OF THE MONTH

FLOWER GARDEN.

ANNUALS AND BIENNIALS.—Make further sowings of clarkia, iberis, lavatera, godetia, ageratum, etc. Sow thinly and cover lightly. Thin annuals sown last month. Prick off hardy annuals into reserve beds. Plant out at end of the month stocks, asters, etc., after hardening off. Sow Canterbury bells, Campanula pyramidalis, hollyhocks, myosotis, scabious, wallflowers, sweet williams, etc.

AURICULAS AND POLYANTHUS.—Sow outside. Lift and divide old plants after flowering. Plant out in a shady border. Water if weather is dry.

BEDDING.—Harden off bedding plants. Plant out the hardiest at the end of the month. Lift spring bedding when finished and prepare the beds for summer plants.

BULBS.—Dry off those not required for the wild garden.

CANNAS.—Harden off. Stand outside and expose fully to sun.

DAHLIAS.—Harden off. Plant out first batch at end of the month.

HERBACEOUS BORDERS.—Stake and tie up growths. Weed and hoe regularly. Thin growths of phlox, helenium, rudbeckia, etc. Thin out shoots of choice asters.

HOLLYHOCKS.—Transplant autumn sown seedlings. Plant out seedlings in frames.

LILIUMS.—Plant in permanent quarters L. auratum and L. speciosum, now growing in pots in frames.

PERENNIALS.—Continue to propagate by means of cuttings. Mulch choice perennials with short manure.

PRIMROSES.—Plant out in shady positions.

ROSES.—Stake standards. Guard against rose maggot. Syringe with "Abol," or with soft soap and tobacco solution. Tie in growths of climbers and ramblers. Feed with liquid manure at intervals.

SWEET PEAS.—Sow to form a succession. Pinch side growths of young plants. Tie up to stakes. Water during dry weather.

VIOLETS.—Hoe between the rows. Water if dry. Spray in the evenings to keep down attacks of red spider.

WATER AND BOG GARDEN.—Plant aquatics and waterside plants now.

LAWNS.—Mow, cut all edges, and roll regularly. Weed and apply worm killer. Give a dressing of a good lawn manure.

HARDY FRUIT.

APPLES AND PEARS.—Examine for aphis and spray soon. Keep down American blight. If roots attacked inject carbon bisulphide into the ground 2ft. away from the stem.

APRICOTS.—Thin the fruit partially, leave the remainder of the work until after stoning.

BUDDED TREES.—See that the young shoots are securely tied, otherwise they may be damaged by wind.

CHERRIES.—Syringe dessert cherries regularly with soft water to keep the foliage clean. Spray with quassia solution if attacked by aphis. Repeat the spraying two or three times until attack has abated.

CURRANTS.—Keep ground clean round black currants and encourage basal growths. Syringe with tobacco and soft soap solution for currant aphis.

GOOSEBERRIES.—Dust with hellebore powder or spray with quassia extract to keep down gooseberry sawfly. Sprinkle lime under young trees.

GRAFTED TREES.—Secure grafts and remove all shoots below the grafts.

PEACHES AND NECTARINES.—Disbud the shoots. Tie in young growths left. Pick off leaves infected with leaf blister. Spray with sulphur and soft soap if mildew present.

PESTS.—Spray with Bordeaux mixture trees infested with leaf-curl.

STRAWBERRIES.—Plant out forced strawberries. Give a dressing of artificial manure before bedding down with straw. Use superphosphate at the rate of 2oz. per square yard and water in. Place nets over the beds before the birds are likely to do damage.

RASPBERRIES.—Thin out weak canes. Give a mulching of rotted manure and several soakings of liquid manure.

WALLFRUIT.—Water frequently. Remove any protection, dry the blinds, etc., and store. Syringe on warm afternoons. Syringe with nicotine solution to prevent damage by insect pests.

GENERAL.—Thin stone fruit. Spray with arsenate of lead when the fruit has set. Water newly planted trees.

VEGETABLES.

ASPARAGUS.—Keep the beds clean. Feed with liquid manure. Do not cut too heavily.

BEANS, BROAD.—Make a final sowing of a late kind. Pinch tops when black fly seen.

BEANS, SCARLET RUNNERS AND FRENCH.—Sow in drills in the open. Plant out, after hardening off, those raised in boxes.

BEETROOT.—Thin seedlings 6ins. to 9ins. apart, and make a sowing at the end of the month in showery weather.

BROCCOLI.—Prick out those sown in April.

BRUSSEL SPROUTS AND CABBAGE.—Plant out on prepared ground.

CARDOONS.—Sow seed now.

CARROTS.—Hoe. Thin seedlings. Dust with soot when foliage damp.

CAULIFLOWERS.—Plant out at end of the month early varieties.

CELERY.—Prepare more trenches if necessary and plant ridges with lettuce. Prick out late supplies. Plant during the third week the main crop supplies.

CHICORY.—Sow in a sheltered position.

CUCUMBERS.—Harden off ridge varieties sown under glass. Plant on hot bed when weather warm. Syringe foliage twice a day.

LEEKS.—Finish planting out before middle of month.

LETTUCE.—Make further sowings. Tie up heads ready for blanching. Thin seedlings. Place soot and lime round plants to keep off slugs.

MARROWS.—Harden off those under glass. Plant out if weather congenial. Cover with hand lights at night.

NEW ZEALAND SPINACH.—Plant out seedlings now in frames.

ONIONS.—Guard against onion fly. Dust with soot. Thin to 4ins. to 6ins. apart. Hoe regularly and give occasional dustings of a fertiliser.

PARSNIPS.—Thin out and hoe in between.

PEAS.—Stake, make further sowing of marrowfats. Pinch tops as they come into bloom.

POTATOES.—Earth up earlies.

RADISHES.—Make sowings of French Breakfast. Water regularly.

TOMATOES.—Harden off well and plant out at the end of the month against a south wall. Sow autumn fruiting tomatoes.

TURNIPS.—Sow in cool, shady border for late summer supplies.

SHRUBS.

FLOWERING SHRUBS.—Prune forsythia, ribes, syringas, etc., after flowering.

HOLLIES.—Transplant now. Lift with a good ball of soil. Water when in new position.

FLOWERS UNDER GLASS.

AGAPANTHUS.—Give occasional feeding with liquid manure.

ARUMS.—Stand outside in sheltered corner after flowering and gradually decrease supplies of water.

AZALEAS.—Top-dress or re-pot after flowering. Stand outside on boards in partial shade. Do not let them suffer from lack of water.

BEGONIAS.—Pot on tuberous rooted kinds at the end of the month, if required for inside decoration.

CALCEOLARIAS, HERBACEOUS.—Stake and tie, fumigate for aphis. Sow a batch in pans.

CHRYSANTHEMUMS.—Give final potting at end of month if sufficient roots made. Pot very firmly. Pinch points of single and bush varieties. Give preliminary stakes. Do not pinch late varieties. Stand outside on boards if weather good during fourth week.

CINERARIAS.—Sow in pans and place in a cold frame.

CYCLAMEN.—Shake out old corms and start them in a bed of leaf soil. Spray young plants daily and stand in frames.

CYTISUS.—Stand outside after flowering. Pot off rooted cuttings.

LILIUMS.—Top-dress as roots appear on the surface. Give more water as growth increases. Ventilate freely. Damp down each morning and watch for aphis. If attacked, fumigate at once.

PELARGONIUMS.—Stake and tie. Feed well. Pinch the points.

PERPETUAL CARNATIONS.—Transfer to frames and stand on bed of ashes. Stake and tie. Feed occasionally. Re-pot when necessary. Syringe to keep down red spider.

PRIMULAS.—Prick off into pans and place in frames for the summer.

ROSES.—Give dose of liquid manure and disbud.

SALVIA PATENS AND COLEUS.—Take cuttings, insert in sandy compost.

SPIRÆAS.—Plant out after forcing in a shady position.

GENERAL.—Pot on all young stock as soon as sufficient root made. Ventilate well. Shade if sun hot, damp down, attend to watering carefully. Water twice daily if temperature rises considerably.

FRUITS AND VEGETABLES UNDER GLASS.

APRICOTS.—Tie down young shoots. Do not tie tightly at first. Ventilate well.

FIGS.—Maintain warm, dry atmosphere for figs in pots and cease syringing when fruit ripening. Water fig borders with liquid manure.

MELONS.—Support the fruits. Pinch, stop and tie shoots. Syringe and water carefully. Give a top-dressing when roots appear through the soil. Sow seed for late crops.

ORCHARD HOUSE.—Give good supplies of water and occasional doses of liquid manure. Spray with nicotine solution to keep down aphis. Thin gradually the fruits when set. Remove weak laterals.

PEACHES AND NECTARINES.—Give more air, ventilate well during the day. Mulch with rotted manure after stoning. Temperature higher during stoning period. Feed as fruit swells. Use liquid manure, guano or Thomson's vine manure. Tie down loosely the new shoots.

VINES.—Keep temperature even. Ventilate well whenever possible. Water well. Thin grapes. Stop sub-laterals. Pollinate muscats. After thinning sprinkle border with artificial manure and give a mulch of farmyard manure.

CUCUMBERS.—Pinch shoots. Top-dress mounds. Syringe and damp down. Plant out some in frames and syringe daily.

DWARF BEANS.—Make a sowing in a cold frame.

MARROWS.—Pollinate the fruit. Feed when swelling.

PEAS.—Give doses of weak liquid manure when pods swelling. Ventilate well.

TOMATOES.—Pot on plants for fruiting outside. Use 6in. pots. Remove side growths and gradually harden off. Top-dress and give a quick acting liquid fertiliser to plants in pots for fruiting in the houses.

SIMPLE GARDENING

GROWING ANNUALS FOR EXHIBITION.

ANNUALS are grown now by everybody who possesses a garden large enough to contain a few beds, or even one small border. As classes at shows are provided for the cut flowers, exhibitors are numerous, too, in some districts. There are new exhibitors every year, and the majority are not conversant with the culture and staging of the plants and flowers, respectively. Many kinds of annuals are "weedy" in habit when not well grown, and quite attractive when well cared for. It is from the latter that prize flowers are cut. I am presuming that the soil has been deeply dug or trenched, as a shallow-tilled soil is not an ideal one for the plants. It should be moderately rich, too, as weakly plants are not able to produce strong stems bearing fine flowers. Many hardy annuals are raised from seeds sown in the open border direct. Of course, slugs are troublesome and often thin out the seedlings too severely; but early thinning-out should be the rule, so that every plant has room to attain full size. Early staking, with neat stakes, is also essential. During hot spells plants in light soils should be surface dressed; timely feeding and regular watering in dry weather should not be overlooked. Remove fading flowers, stage those that are fresh, richly coloured and even in size. Always cut the stems long enough, then light arrangement is possible. The following is a selection of twelve kinds: Phlox Drummondii, Yellow Sultan, Cyanus minor, Jacobæa elegans, Clarkia elegans, Linaria reticulata, candytuft, godetia, mallow, linum, collinsia, poppy.

FEEDING PLANTS.

Many inexperienced cultivators think that all plants require feeding, and make serious mistakes. Sickly-looking plants —those having yellow leaves—and tiny ones, looking stunted and so on, are regarded as being fit specimens for feeding. Now, all such plants, grown in pots, should be carefully examined before stimulants are applied. Food must be taken up by the roots, so if the latter are few in number or some of them are dead, it is useless to apply a stimulant; in fact, it does more harm than good. Turn out the plants and ascertain if roots are freely permeating the soil round the sides of the pots and that the drainage is good. If these conditions obtain, then food is required by such plants. We can now obtain, at reasonable prices, concentrated manures suitable for all kinds of crops. The wise course to take is to follow the instructions and err on the right side—that is, apply rather weaker doses than stronger. The principle of using a small quantity and often, in preference to big doses and seldom, is a right one. All soils should be moist when manures are applied, by rain or thorough applications by water-can. About one hour after the soil has been moistened by clear water is an ideal time for applying manures as stimulants. Seedlings should not be treated with such stimulants. Good soil and careful watering with clear water are all they need in this way. Sickly plants should be similarly treated—nursed carefully, not fed.

HOW TO PREPARE CELERY AND LEEK TRENCHES.

As a passer-by one sees celery and leek plants growing in many gardens, some making satisfactory progress and others doing badly. When the late summer and autumn shows come one sees, practically, the season's growth of these plants, and the same tale may be told. Both kinds of plants require high cultivation and, though the inexperienced may be aware of this, he thinks that high culture consists chiefly in making deep trenches for the plants; he grows the plants in the poor subsoil and blanches them in the top good soil. I would like to urge cultivators to grow the plants in the best soil; if trenches must be made, then be content with very shallow ones. Take out the top 9ins. of soil and place it on one side of the trench, and the second 9ins. on the opposite side. Then fork into the subsoil a liberal supply of well rotted manure, loosening and breaking up that subsoil thoroughly. The next thing to do is to return the first soil removed in making the trench and to improve it by adding wood ashes, rotted manure and bone-meal. If wood ashes are not available, use soot. Mix all ingredients with the soil. Result: the trench will be about 6ins. deep, below the normal level, and the soil will be improved for the reception of the plants if it remains so until the first part of June. In due course, the second layer of soil removed will be available for earthing-up and blanching purposes.

TUBEROUS BEGONIAS.

I strongly recommend these plants for the greenhouse and the garden during the summer months; they are very charming and economical plants to grow. In both dry and wet seasons the foliage remains fresh and the flowers numerous and brightly coloured. The colours in mixed beds do not offend the eye as those of some other kinds of plants do. Owners of small gardens may soon obtain a supply sufficient for their needs by writing to firms who grow fine batches of plants and advertise them in THE GARDEN. Whether they do this or raise their own stocks, the borders should be prepared by deep digging and adding to the original soil some fibrous loam and a small quantity of half-rotted leaf-soil; not any peat.

It is very important that the growth be short-jointed and sturdy, then there will be few losses through strong winds breaking off stems. With regard to plants for greenhouse and conservatory, all such may be successfully grown without the aid of fire heat; and, provided sufficient ventilation be the rule, shading is quite unnecessary save in the case of a greenhouse in a very hot corner. GEORGE GARNER.

ANSWER TO CORRESPONDENT

Conservatory and Greenhouse (I.O.M.) —Seed of Lathyrus pubescens can be obtained from Messrs. Thompson and Morgan, Ipswich, who also used to offer seeds of L. splendens. If unobtainable there, we should advise you to write to Messrs. Howard and Smith, Olive Street, Los Angeles, California, U.S.A.

VERMOL

KILLS WORMS AND GROWS GOOD GRASS

Vermol Lawn Sand (Weed Killer)
Vermol Grass Manure (for impoverished turf)
Vermol Insecticide (for Leather-Jackets and other soil pests)
Vermol Grass Seeds (Finest Mixtures for all purposes)
Above specialities also highly recommended.

What users say of Vermol:—

DENHAM GOLF CLUB.

"We commenced using the five tons of VERMOL WORM DESTROYER last week and can assure you that it is absolutely satisfactory.
"Our experience is that it has a much quicker action than any other worm killer we have used, as the worms come to the surface as soon as the watering in is commenced, where they die immediately. We are convinced that, comparatively, it is the cheapest and best preparation on the market."

WHERE WILL IT END?

THE rhododendron show last week will bring home to gardeners more than anything else the plethora of species and hybrids that are now appearing on the scene. Although there are many fine hybrids which I am proud to grow, yet I have always stated my preference for species, and for this I am often considered a crank. Many species only differ in slight botanical characteristics, and so, to the ordinary gardener, may appear as closely resembling each other as do hybrids; but there is this difference, that species on their arrival into this country usually get into experienced hands and are weeded out before they reach the ordinary garden; also, most species come true from seed, with, perhaps, only slight variation of colour. The consequence is that the ordinary gardener will in time get together a collection of species; but they will be a selected list, weeded out for him by experts.

Unfortunately, this is not the case with hybrids. Owing to the fact that they are not fixed plants, a pod of a rhododendron which is in itself a hybrid, or a pod from a species which has been fertilised by another different species, will produce a collection of offspring of great variety which may lie anywhere between the parents. A number of years may elapse before their worth can be judged, and it is only natural that hybridists, who have spent infinite time and labour in growing these plants, will feel chary about discarding any except the obvious ugly ducklings; but the weeding out process is not nearly thorough enough, and many new hybrids appear under names which are practically the same as something else already in existence. This does not apply only to rhododendrons, for this craze for hybridising has reached into many corners of the garden.

Now, what is the object of hybridising? Either to improve on something already in existence or to supply a form which does not appear in nature. It is said, and it is certainly true, that hybrids are more vigorous than species; but is it necessary to have a more vigorous plant? Vigour often tends to coarseness of growth, and coarseness of growth leads to lack of individuality and so removes one of the greatest charms that rhododendron species possess. It is also said that hybrids are hardier than species, but this I very much doubt. Most of the rhododendron enthusiasts live in an equable climate, which is one of the reasons that they have become enthusiasts. It is only those who live in the east or the north who can really decide upon the hardiness of rhododendrons in general, and I should certainly say that hybrids, with the exception of those with caucasicum blood, are just as liable to frosting as many species.

There are certain obvious lines upon which rhododendron hybridists can work, hybrids which will flower from July onwards, yellow rhododendrons and blue rhododendrons. So far these rhododendrons are conspicuous by their absence; in their place we get numbers of luscious-looking hybrids in good colours, which are very fine in their way; but are they any better than what we have seen before? They are certainly not hardier, nor are they better growers. If half a dozen various hybrids were placed in a row it might be possible by direct comparison to pick out the best, but the improvement noticeable is usually very slight. In my opinion, the most useful new hybrid shown at Vincent Square last week was Messrs. Van Nes' cross between Azalea Hinodegiri and A. Kæmpferi. If you like those small and very free-flowering azaleas of the Hinodegiri type, with colours that sometimes may be harsh but are always brilliant, here is a distinct advance, for Hinodegiri is not hardy except in the extreme south and west, while the new hybrid apparently stands our weather perfectly. There was nothing exactly of this type before, so for those who like this type of plant the new hybrid is a decided improvement.

As I said before, these remarks do not only apply to rhododendrons. Slight improvements in varieties and hybrids are of little use to the ordinary gardener; what he wants are wider breaks and fewer of them. What is required is some central hybridisation authority where a committee would appraize the worth of a new cross after testing it alongside of its older neighbour. There are a number of useful lines on which a hybridiser can work if it is hybridisation that interests him. Let him try to evolve a soya bean that is suitable for cultivation in this country. Then, again, no one has ever used any of the many admirable rubi from China for producing a new berry, by crossing with a raspberry. Who knows what luscious morsel might not be produced?

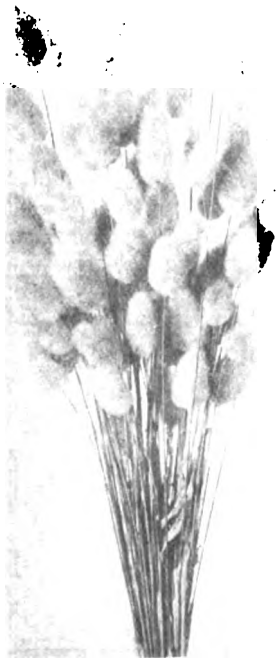
DECORATIVE GRASSES

FOR INTERIOR DECORATION IN THE WINTER MONTHS THE GRASSES WITH THEIR CHARMING HABIT AND GRACEFUL INFLORESCENCES ARE HARD TO BEAT. A SELECTION WHICH WILL BE FOUND USEFUL IS GIVEN IN THIS ARTICLE.

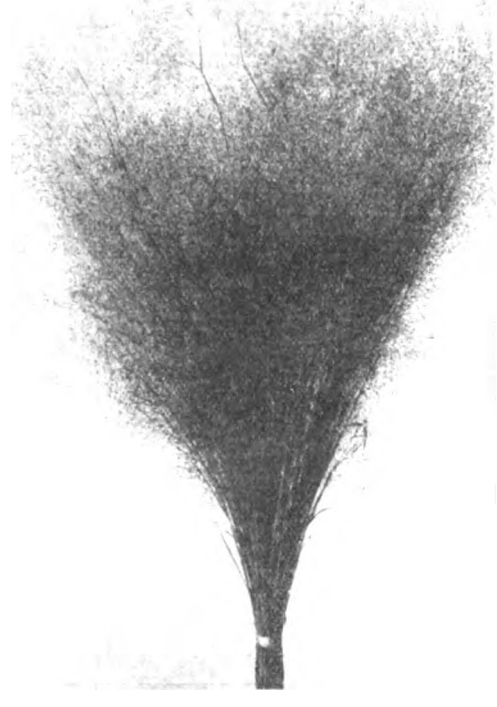
WINTER extends over a long period, and not everybody possesses the means of making his home gay with greenhouse or imported flowers. Ornamental grasses can, to a certain extent, serve as a substitute, especially if a good selection of them is made and a change made occasionally in the vases before heat, dust, etc., have altered the exposed inflorescences. These ornamental grasses can be grown very easily and at very little expense in every garden. All they require is moderately good ground and an open situation. The reason of their not being more generally grown rests certainly in the fact that they are usually harvested at the wrong time—that is, when the vegetation is nearly at an end and their seeds are nearly ripe. The result of this is that the inflorescences are of a washy colour and the spikelets soon drop. If everybody had the foresight to cut the stems when still in a green state, soon after flowering has taken place, the result would be infinitely better. It would, in fact, be a revelation to many who have no idea of the gracefulness and the diversity of ornamental grasses in general and of their possible uses. There can be, of course, no question of comparing these grasses with lovely fresh flowers; but during the absence of everything brilliant from the garden, from November till March, everyone becomes less exacting in his requirements, and what would have been considered an item of medium interest in the height of summer becomes then, when handy, of some value for decoration.

Although, on some occasions, it is possible to grow ornamental grasses directly in the border or in the pleasure garden (as in the case of Tricholæna rosea and Paspalum elegans, for instance), it is best, as a rule, owing to the ugly look of the plants after the stems have been cut to cultivate them in an odd corner in the kitchen or back garden. There the gardener can keep them constantly under his eye and cut the stems as soon as desirable without taking any notice of the look of the plant afterwards. As soon as harvested, the inflorescences are laid in a dry, airy place where they can gently come to a dry state, at what time they can be put together into small bunches that are kept away from any dust pollution till they are wanted the following winter.

Many common and native grasses are ornamental and can be used for decoration when properly harvested. But for anyone who wants to grow really showy subjects, the best thing is to adopt only commercial kinds, mostly exotics, that are offered in catalogues. These commercial grasses can be divided into two classes: the annual and the perennial ones. Probably the most important and the showiest are the annuals, perennials having the advantage, of course, of coming up year after year and of requiring less attention. A number of the latter, however, are best treated as annuals, owing to their susceptibility to winter cold and dampness.



LAGURUS OVATUS WITH SHOWY INFLORESCENCES.



THE LIGHT GRACEFUL PANICLES OF OF AGROSTIS NEBULOSA.

THE BROAD FLATTENED SPIKELETS OF BRACHYPODIUM DISTACHYUM.

The following species and varieties can be given as a selection among those that are most suitable:

AGROPYROM CRISTATUM.—Perennial; 2½ft.; ears erect, flattish, vivid green.

AGROSTIS NEBULOSA (A. CAPILLARIS).—Annual; 1½ft.; exceedingly light and graceful panicles.

AIRA CÆSPITOSA VIVIPARA.—Perennial; 3ft.; effective if cut at an early stage.

BRACHYPODIUM DISTACHYUM.—Annual; 1ft.; broad, erect, flattened spikelets. Very charming.

BRIZA GRACILIS, B. MAXIMA, B. GENICULATA, B. MEDIA.—The three first mentioned are annuals, the last perennial. These well known grasses have the most graceful aspect. B. maxima has the largest spikelets.

BROMUS MACROSTACHYUS.—Annual; 2½ft.; erect habit. A most decorative grass.

BROMUS PENDULINUS.—Annual; 1½ft.; large, flattened, drooping spikelets.

CHLORIS BARBATA.—Annual; 1½ft.; digitate, highly decorative inflorescences of a very unusual type.

Digitized by Google

CHLORIS DISTICHOPHYLLA.—Annual and perennial; 1½ft.; very showy, but a strong lover of heat.

COIX LACRYMA-JOBI.—Annual; 2½ft. This is the well known "Job's Tears" plant that America is beginning to use as a forage in hot districts.

ERAGROSTIS MAJOR (E. MAXIMA).—Annual; 2ft. Probably the most showy of all eragrostis. Large erect panicles. Mention may also be made of E. Fontanesi and a few others with more slender inflorescences.

GYNERIUM ARGENTEUM.—Perennial; 8ft. This is the well known pampas grass, common in many gardens. Pink-flowered varieties are also very showy.

LAGURUS OVATUS.—Annual; 1½ft.; very showy inflorescences of most graceful and light aspect. A first-rate plant.

LAMARKIA AUREA.—Annual, ½ft.; a dwarf plant with yellowish, silky, pretty spikelets.

LASIAGROSTIS CALAMAGROSTIS (CALAMAGROSTIS ARGENTEA).—Perennial; 3ft.; graceful arching panicles.

MELICA PENICILLARIS.—Perennial; 3ft.; erect inflorescences of white, very light appearance. Other melicas are also beautiful: MM. ciliata, nebrodensis, transylvanica, etc. Melica altissima rubra has lovely tinted red inflorescences.

PANICUM VIRGATUM.—Perennial; 4ft.; light inflorescences. One of the best perennial ornamental grasses.

PENNISETUM VILLOSUM.—Perennial; 2½ft.; silky heads of showy aspect. A most lovely plant. The form atro-purpureum has nicely purplish tinted heads.

PHALARIS CANARIENSIS.—Annual; 3ft. This is the well known Canary grass, quite showy if harvested early.

PHLEUM ALPINUM.—Perennial; ¾ft.; tiny erect ears, very graceful. Phleum Boehmeri, of about the same type, has ears distinctly stouter and shorter.

POLYPOGON MONSPELIENSIS.—Annual; 1ft.; dense, erect, cylindrical inflorescences. Distinct and elegant.

STIPA GIGANTEA.—Perennial; 3ft.; showy, extremely light inflorescences, very long-bearded. S. tortilis has curiously twisted beards. S. pennata, silky, arching, slender panicles. All are great sun lovers.

TRICHOLÆNA ROSEA.—Annual, 3ft.; beautiful light pinky inflorescences. A charming item either in a green or in a dry condition.

Inclusion must also be made among ornamental grasses, to be complete, of many utilitarian plants: millets of all classes, many of which have coloured and very graceful spikes or panicles and are very showy; numerous varieties of wheats, oats, barleys, ryes, etc., commonly cultivated for production, but having very decorative ears, bearded and unbearded, coloured or uncoloured, slender or stout.

The propagation of most of these grasses is easy. Sowing takes place in spring, in March and April, either in the ground the plants are to occupy, or in a nursery bed, or in boxes under a cold frame. In the two last cases it is necessary to transplant when the plants are large enough. For some species, that are natives of warm countries, such as panicum, coix, briza, setaria, eragrostis, etc., it is best to delay the sowing till a little later in May, when the ground has become quite warm. The only care required by these grasses during the growing period is an occasional hoeing and cleaning of the ground. C. LERAY.

THE PALE PRIMROSE

Ring-ting! I wish I were a primrose,
A bright yellow primrose blowing in the spring!
The stooping boughs above me,
The wandering bee to love me,
The fern and moss to creep across,
And the elm tree for our king!

—WM. ALLINGHAM.

IT is something of a coincidence that the day which we call Primrose Day, April 19th, should be not only kept in memory of that great statesman, Disraeli, but the day of his death was also the day of Darwin's death a year later: "Dizzy" passing in 1881, Darwin in 1882. Darwin and Knight wrote important treatises on the primrose, and its thrum-eyed and pin-eyed, or short and long styled forms, and gave us such illuminating ideas on the subject of cross-fertilisation of plants.

In mild seasons one may find the primrose out in February, but it is undoubtedly at its best in April and May.

In its colour the primrose differs from other yellow flowers so much that the name primrose has been applied to the pale yellow of this flower. Cultivated, the primrose produces flowers of various colours from white to pink, and even bright red. Really the primrose is as much a primula as the garden forms of other species which always go by the name of primula. But Primula acaulis proper is always called the primrose, while its garden colour varieties are called primulas. Others which differ from the primrose in its usual form are known as polyanthus. They differ from the ordinary form of primrose in having several flowers formed on an umbel like the cowslip, but occasionally the wild primrose produces this polyanthus form.

Milton calls it the "rathe" or early primrose, and it is very uncertain in its time of flowering. Those forms we have noticed with several flowers on one stalk are popularly known as oxlips. But they are not really oxlips, for the true oxlip grows only in certain counties—

THE DAINTY COWSLIP.

Essex, Cambridge, Herts and Suffolk—differing in the size and colour of the flower, and much more like a large cowslip without the spots. In the primrose there is a long, slender stalk, longer than that of the cowslip, and it rises deep down in the root-stock among the thick rosette of leaves. The stalked primrose is like a cowslip, with the flowers on a common stalk. In the primrose it is usually quite short immersed among the leaves. Occasionally the primrose and the cowslip hybridise, some forms being more like the cowslip, some like the primrose, others quite intermediate.

Some years ago I collected one of these hybrids in Rutland in a wood in which grew the wild columbine, the mountain St. John's wort, belladonna and many other interesting flowers. Some roots were transplanted to the garden, and after increasing were divided up. One large root was divided up into twenty smaller pieces, and used as a border to a square bed. When these roots had become established they came into flower, exhibiting, in nineteen cases, the hybrid character, in this case much like the so-called "oxlips." By this I do not mean the very large cowslips—which are merely luxuriant shade or woodland varieties with flower-stalks sometimes a foot long—but the large-flowered cowslip primrose form with flowers twice as large as the cowslip and yellower than the primrose, but unspotted. The colour was intermediate, more golden than the primrose tint, but not as yellow as the cowslip flower.

One root, the twentieth, had leaves like the cowslip, which are quite unlike primrose leaves in shape, colour and the amount of wrinkling. The flower was small and exactly like a cowslip. In fact, this twentieth root was a true cowslip. It was broken off the original hybrid cowslip-primrose root. There could be no more striking proof of the hybrid origin of the original root. It showed that the hybrid had more of the cowslip in it than the primrose, though the original plant had all the flowers when gathered like the other nineteen subdivided plants, and no trace of a normal cowslip flower or leaves. In the course of growth the old plant had developed unequally,

Digitized by Google

and one portion of its original rootstock had thrown back, or had been untouched by the hybridising agent, which had affected the rest of the rootstock.

I know of no other instance of a hybrid exhibiting so clearly the hybrid origin and in the *vegetative* part or rootstock revealing one of the true untouched parents of the hybrid. The case is extremely interesting, as it shows that, apart from the reproductive factors, and the hybridising or crossing, and breeding on Mendelian lines with known results for each generation, one may have other methods of arriving at results by ordinary vegetative propagation. If a piece of a hybrid root can throw off one of the original parents, while retaining for the rest its hybrid characters, propagative methods may be developed to discover the origin of hybrids thought to be true species, and be used also to develop new forms by crossing alternatively with propagation by vegetative methods.

To revert to the forms of the primrose, "pin-eyed" and "thrum-eyed," it is not generally known that these terms owe their origin to the amateur cultivators of the auricula, a garden allied form or species, at Nottingham, who, using the terms familiar to them in the art of weaving, applied the name thrum-eyed to the form with five projecting anthers in which they saw likeness to the ends of the thrum, and so the other long-styled of pin-eyed form was so named because of the pin-like character.

Take a few primrose flowers from a grassy bank and it will soon be discovered that not all are alike. In some flowers, from the long tube a green pin-headed structure, the style, projects. Another flower will not have this, but instead in a ring round the mouth of the tube are shown five yellow points. These are the anthers. The style is short and half-way down the tube in this thrum-eyed form. Such a flower is dimorphic, or possesses two forms, a long and a short styled, and by visiting different forms an insect cross-pollinates them. The pollen in the short-styled form touches the insect at such a part of its body that it will come into contact with a style only in the long-styled form; and conversely the short-styled form is crossed with pollen from a long-styled form, in which the anthers are half-way down the tube, and so just at the point where the style in the short-styled form is situated. Many variations of crossing occur in such dimorphic forms. The pollen from a short-styled form is more prepotent or fertile when applied to the stigma of a long-styled form, than to a stigma of a short-styled form, and conversely. Cross-pollination was held to be more efficacious than self-pollination by Darwin, and his experiments and evidence bore out this view. But such a rule is not of universal application, and there is a more modern view that the opposite is the case. It is quite obvious that it is not essential nor that it is always beneficial, nor even possible. It is a fallacy to argue from the particular to the general. In some cleistogamic flowers, such as the violet, later-flowering forms which follow the spring flowers, cross-pollination is precluded, for the flower is closed. Some other plants seem to be best adapted to self-pollination. In the dioecious plants cross-pollination becomes a fairly certain occurrence. And in wind-pollinated trees and other plants cross-pollination is the rule. Again, the example I have given shows that vegetatively plants tend to return to type in the case of hybrids or cross-pollination between different species.

We have to depend on the choice of insect visitors in a state of Nature. But a world of possibility lies before the gardener or plant breeder.

A. R. HORWOOD.

A CLUSTER OF PALE PRIMROSES.

NATURE'S ROCK GARDEN

BY HALLIWELL SUTCLIFFE.

THERE is rather widespread belief that rock gardening is a whimsical affair, artificial in conception and practice. Some such gardens, do, indeed, suggest that their creator made up his own rules as he went along, according to the day's mood or the material that came most readily to hand. But the craftsman who builds truly and for heart's delight must have learned in one school only—nature's.

And what a school! Here in our Northern heights, lean pastures climb to the sky and the grey limestone walls rake out across the lonely places. Few voices break the stillness. A shepherd's call, his dog's brief reply—the forlorn bleating of ewes, ingathered against their will—wail of a soft-flapping curlew, or drumming of the snipe—these are your only gossips, until little by little you begin to hear what seemed the silence of the rocks.

This land is little changed since the elder days. It wore the same aspect when the first beaked ships crossed Viking seas. The cave dwellers saw it much as we see it now. The Britons, who made their last stand in the North on the hill above, knew it as we know the curling slopes, the thinly-wooded heights. Mating and birth time—laughter and wooing of the men and women who ran life's gamut, and passed—the quiet rocks are their chronicle, once you have learned their speech.

An odd thought recurs to one persistently in crossing these rock-strewn acres. That last stand of the British was only the final chapter of a long and moving tale. Their ruined camps abound, and all along this savage country there were running fights and skirmishes, year in, year out. Many of these stones must be lying where they fell

Digitized by Google

after British warriors had rolled them on to the oncoming foe. There are times when the rocks are in a mood to talk of nothing but rude strife. In the silence of a brooding winter's dusk, for instance, you will see nothing, but will be aware of conflict, stark and terrible. You will hear no actual yells, no death-cries, except as it were from a long way off. But all is real. The stones are telling you Saga tales, and you cannot choose but listen.

One mighty boulder—we name him the Monarch of the Glen—is oftenest in this mood of joy in bloodthirstiness for its own sake. He stands alone among the sheep-cropped grass. Nobody knows how deep his feet go. His head and shoulders stand bulky and triumphant, though storm and frost and blistering heat have chiselled fissures, deep and wide, about his person. The story he loves best, among all his trenchant tales, is of a British Queen who slept one night in a near-by cave, and the next morning gave battle to the foe, leading her men to do or die for her. They died, to a man, and folk nowadays disturb their bones at times and hale them, without due trial, to some museum's prison.

The Monarch tells you how, when all was lost, the Queen came, heavy with wounds, and leaned against his scarred, trusty bulk. She told him how her men had fought—laughed once, for pride in them—and so went along the busy highway of the dead.

He is proud of his British Queen, of the men who fought rearward battles in the long and ever so long ago. He fought the dint of weather and hard circumstance long before their time; and still he's here, glad of life and of sheer tenacity to hold his own.

The Monarch of the Glen has his softer moments. They come when spring breathes warm across a wintry land, and plovers cry about their nesting places, and virile hope stirs the young sap in age-old thorns. The great weather gaps that seam the Monarch have gathered wind-blown leaves and held them till they rotted, mixing with the worn limestone scrapings; and vagrant seeds have strayed into these warm retreats. He is father, indeed, of a mixed brood, and from spring right on into the October days he is a garden in himself.

You would not look for the earliest primrose on these open heights, unless you chanced to know that in a cranny of the Monarch, on the west side, a strong clump has found protection from every wind that blows. No word can explain the young, eager mystery, the fresh, sufficing beauty of these blossoms, with grey rock for background.

Nor is it easy to tell of the rock rose's magic, later on when full-o'-the-year is flooding the thirsty land with heat. They have made one big pocket their own, and their roots, fibred into the porous stone, drink from an unfailing well. No drought can hinder their riot of bloom. The hotter the sun, the more they smile up at him as at a welcome friend.

The little white-flowered saxifrage has staked a claim all down the Monarch's eastern side — a joyous youngster that creeps every way, like a babe on the nursery floor. Its foliage alone is a year-long delight—green as if new-washed by rain a moment since — and its habit is to follow every dip and curve of the crannies, painting, but not hiding, the rock's bold features.

In this same area that I have in mind, not far from the Monarch, a rock garden of quite another type climbs the pasture till it steps, still upward, into a beguiling belt of low-growing trees and shrubs. Surface stones and deep-set rocks are intermingled, with the seeming carelessness that perfect art should have. All the bold effects are secured by proneness, and it is here that one learns—half consciously and by long companionship—how a man-made rock garden should rise and fall and undulate.

Every worker in this sort of craft knows that there are times when he cannot go wrong. His rocks seem to play themselves into place, as it were, with melodies; and in my own experience I have found that these inspired hours are apt to follow some prolonged excursion up to the rocky highlands. Observation has something to do with it, no doubt; but there is more—much more. One has breathed in the spirit of the rock world, and the subtle elixir is with one on returning.

The surprises of these wide-flung gardens lie in wait at every turn, and one is never sure what feast of colour is in store, or what lace-fronded clump of ferns, deep pocketed, will meet one unawares. Wild thyme, on the open slopes, throws its strong, ruddy mantle over the baked rocks. Farinosa, mealy, yet tenacious, makes pink wonderlands among the sober limestone grey. These are summer's children, but earlier in the year another quiet dweller in the rocks glows into full life.

I have seen cowslips in lush meadows, under wayside hedges, in all their usual haunts. But their grace is never so compelling as when they choose the gaunt rocks for harbourage. Their golden belfries, ringing home the bees, nowhere else, somehow, wear just this charm, and no breeze but the highland's entices the same fragrance out.

If rarer plants are your quest, you shall find Dryas, oak-leaved and pearly white of flower; and in one place, if sheer luck guided your feet there, you would happen on a free-blooming plant, housed between two crannied boulders, for which many a gardener would sell a year or two of life. It is named the Lady's Slipper; and I say advisedly, that luck alone can guide you to this special haunt. Not one of the few who know will ever give you help in the direction of their yearly pilgrimage.

Where this rock garden of the fells runs into the scanty woodland, a noise of running water tumbles down the steep, and presently you reach a stream that half pretends to be a torrent. A torrent it is in earnest now and then, after sudden melting of the snows above. Great rounded boulders guard its banks, or lie in mid-stream. And here you find a rock-garden distinct in its beauties and surprises from those left below you—a place where kingcups, in their season, stand waist deep in the stream and throw their spendthrift sheets of bloom abroad—a haunt of great, wide-branched male ferns, and curled brackens, and water avens, guarded by sparse hazels and feathery rowans that lean to the cool murmurs underneath.

MR. HALLIWELL SUTCLIFFE'S ROCK GARDEN IN A YORKSHIRE DALE.
From a painting by Ernest Moore.

Where can one call a halt, in this wide travelling from one rock garden to the next? The limit of one's space is reached already, and the journey scarce begun, but any journey of this kind is worth while.

Digitized by Google

SOME ORNAMENTAL VINES

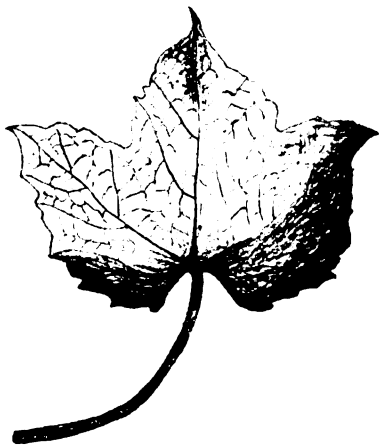
COMMON AND UNCOMMON

BROADLY speaking, "vine" is a term applicable to all plants of twining, trailing or climbing habit of growth, but it will suffice for the moment to confine our attention to such members of the genus Vitis as are grown for ornamental purposes.

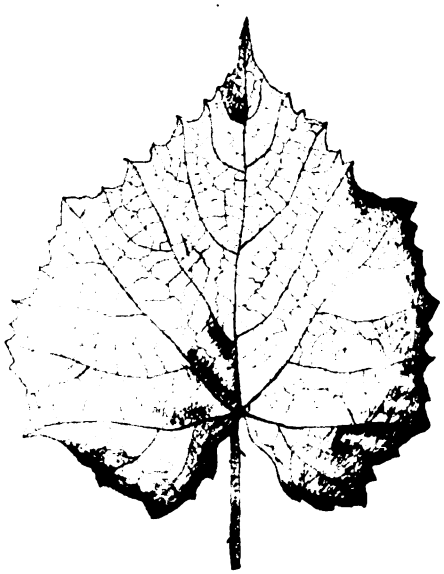
Certain species and varieties of this remarkable genus have been long cultivated in the British Isles, but it was with the dawn of the present century that we acquired such wealth of variety, charm and beauty in introductions from China, thanks largely to the successful efforts of E. H. Wilson, George Forrest and Dr. Henry, that no one who has a particle of love for beautiful plants can differ from the opinion that in this family exist some of the grandest and loveliest of nature's rich productions.

Wherever an ornamental vine is to be planted, careful attention should be given to the rooting medium. A common observation is that vines are gross feeders, but one moment's thought as to the vast area of growth and quantity of substantial foliage an established vine produces will suffice to impress the mind with the fact that the supply of nourishment must, of necessity, be liberal. Deep digging is an absolute essential: on heavy clay soils because it improves drainage, and on light, dry soils because it facilitates descent of the roots to cool, moist areas well below the surface. Of all manure, cow's is best for light soil, being substantial and lasting, while on heavy soil strawed horse manure will be better; but some natural manure is quite necessary, supplemented perhaps, but not substituted, by artificials. Of the latter, coarse bone-meal, hoof and horn shavings, dried blood and fish meal are more serviceable to vines than sodas, sulphates and the like. If a vine is to be planted near to a tree or a coarse-growing shrub, nothing less than a cubic yard of soil should be dug out, mixing the whole with manure before returning, with an allowance of a fortnight at least for settlement before planting.

As to the season of planting, if young plants from pots are to be used (and they are by far the best) spring is the best season for the choicer and perhaps more delicate varieties, because they will have the summer and autumn during which to make root and growth before facing winter. The hardier kinds may be transplanted in autumn if so desired. A very large percentage of failures might be traced to the erroneous idea that it is an advantage to start with big strong plants. A vine in a 6in. pot with three or four runners 4ft. or more in length will have its roots wound many times round the small body of soil in the pot. It would be well if planters overcame the impatient clamouring for big strong plants and sought instead small young plants as soon as they were sufficiently developed to move with safety. Failures would be reduced to a minimum, and the supposed loss of time would soon be realised to be imaginary rather than real.



ONE OF THE FORMS OF FOLIAGE OF VITIS HETEROPHYLLA.



THE HANDSOME LEAF OF V. ARMATA.

THE GRACEFUL TRIFOLIATE LEAF OF VITIS DELAVAYI.

Seldom will the purchaser of a vine which he has impressed upon the nurseryman must be a good strong plant, be persuaded to prune it before it starts to grow at all, yet that is the one time when hard pruning will be of great and permanent benefit. A plant from a pot has rods or stems which, although perhaps several feet long, are of necessity slender. It is planted, and attempts simultaneously to make new roots below ground and young growth from every joint above ground. With very small means of obtaining nourishment the large number of young shoots that break from the eyes of the slender rods are pitifully weak, and (here comes the important point) these are the shoots which should develop into the main or "trunk" branches of the vine to support and nourish all future growths. As an alternative to this let us suppose that the thin rods are cut back before sap begins to flow in early spring, leaving only two eyes at the base of each rod. The roots in the pot-ball of earth will provide sufficient nourishment to give one if not both of the retained eyes a vigorous start, and new roots forming will take up the task of drawing nourishment at a rate increasing about as rapidly as the young shoots extend, consequently maintaining unchecked a steady and strong growth. By the end of the first autumn this plant will have made three or four long, strong rods which, if evenly distributed over the widest possible area, will have laid the foundation of a thoroughly vigorous vine. The unpruned plant will only have succeeded in making a lot of thin little lateral growths which ceased development about halfway through the season, and will never be strong enough to support a big rod, probably also being too weak to withstand the rigours of a hard winter. Reverting to the plant with three or four strong rods. The proper method of pruning these during the following resting period will be to cut them back to half their length, thus encouraging the development of the lower buds, which will then break away with great vigour. Unless thus shortened, the tendency will be for the eyes at the ends (the thinnest part) of the rods to break while those of the lower and stouter half of the rods will remain dormant.

After the second year, pruning may consist chiefly of cutting away weak growths to avoid overcrowding and the removal of accidentally injured wood or of an old rod which can be replaced by a stronger young one.

Much greater benefit will accrue from careful attention at frequent intervals to little details of training than from too eager resort to surgery. There is a way of guiding and securing young growth so that even distribution is secured without the slightest evidence of the handiwork. There should not, in fact, be indication of restraint or

Digitized by Google

measured formality, but it is an immense mistake to imagine that the way to avoid such indications is to allow the vines to grow just as they will for the whole season through; that will result in entangled masses and many strangled growths, tendrils of one rod mercilessly gripping another and preventing normal development.

Ten minutes a day and a piece of soft twine will keep a big vine in perfect order, but neglect for a couple of months may involve a few days of laborious and not very successful effort to rectify matters.

Much depends upon supports. Tree stumps, rustic poles and treillage are not difficult problems, but walls, especially house walls, require careful consideration. Nails and shreds are intolerable and hopelessly inefficient for strong-growing vines. Staples are better, but unless very large, and consequently ugly, are likely to cause trouble when main branches swell. Diamond-meshed wire work is usually made much heavier than is necessary or desirable and, all things considered, it is difficult to beat ordinary 3in. mesh wire netting stretched taut on strained cable wires. With one early tie a young growth will thread its own way through the meshes without further aid, and if the wirework is stretched horizontally in 3ft. breadths there is no necessity to have bare netting exposed to view because a strip can be added from time to time as the extending growth of the vine requires.

Highly decorative and desirable vines are so numerous that only a small selection can be briefly described here, but these include very distinct and beautiful kinds for the most part productive of rich autumn tints and, generally speaking, sufficiently hardy for the majority of gardens in England, Wales and Ireland.

VITIS ARMATA is very handsome, its foliage of large size, heart-shaped, with a long tapering point, conspicuously veined and closely corrugated. A full-grown leaf will sometimes measure 9ins. from stalk to tip and 7ins. across. The autumn tints are very bright, but the richest and most glowing colour is attained by the variety V. armata Veitchii, which becomes literally blood red. V. armata requires ample space.

THE SMALL ELEGANT LEAF OF VITIS HENRYANA, SHOWING UNDERSIDE AND VEINING.

V. COIGNETIÆ.—One of the finest of the large, heart-shaped leaved vines, very closely netted over the whole surface of the leaf, the undersides being densely coated with a felt-like tomentum. Vigorous in habit and usually bright in its autumn tints, V. Coignetiæ is more plentifully planted than many kinds.

V. HENRYANA.—Much smaller, but extremely elegant, the leaves of this species are made up of five leaflets, long-pointed, irregularly toothed and beautifully veined. The central leaflet approximates 3ins. in length, the rest being shorter. The surface of the leaf is beautifully pencilled with white lines following the course of the ribs of the leaf, and a delicate pink stain overlays some portion of the dark green of the glabrous foliage.

V. HETEROPHYLLA.—There are various forms of this vine, some having almost entire leaves, others deeply lobed and toothed. The variety V. h. humulifolia simulates the hop leaf, and there is a variegated form of this variety which is frequently grown in pots for conservatory decoration. It is satisfactory outdoors only when it can climb over a dark surface in a position well sheltered from cold winds, but the ivy-leaved type is quite hardy, and is very showy by reason of its shining red stems and neat foliage. V. h. Delavayi strikes another note, giving us a graceful trifoliate leaf, the central leaflet running to about 6ins. in length. It is broadly toothed, and hangs with a dainty elegance, the veining standing out conspicuously for so light and apparently slender a leaf.

Of VITIS FLEXUOSA several distinct varieties are now in cultivation, the type having serrated, heart-shaped leaves of small size borne on slender string-like stems. A notable feature is the length of time this vine retains its foliage, sometimes until well nigh Christmas. Good varieties are V. f. chinensis, V. f. major and V. f. Wilsoni. A. J. MACSELF.

A WANDERER'S NOTE BOOK

WILD GLADIOLUS AND CYCLAMEN.

The wild gladiolus (G. communis or G. palustris ?) chronicled from Greece is also to be found round the head of Lake Garda, but probably not in any great quantity. Where I found it it was sharing with one of the small dark blue aquilegias that are so difficult to differentiate, a grassy steep slope above the road near Storo, the Austro-Italian village from which one begins the ascent of the famous Tombéa. Cyclamen europæum, that blooms in Greece in winter, is in countless multitude and inimitable beauty all over the lower slopes of the Monte Baldo range that flanks the eastern side of Lake Garda and of the mountains of Judicaria (in which all the European primula species seem to meet and hybridise) that stretch from the now popular resort of Gardone-Riviera to the Stelvio Pass.

NATURAL HYBRIDS.

Are natural hybrids invariably easy of cultivation—relatively, that is—to the species that are their parents ? It is a tempting generalisation and one of the curiosities of Nature. The European section of the primula family, *par excellence*, have almost elevated this rather hazardous suggestion to a general principle. The most apposite and not the least illustrious example is P. Florekeana, a natural hybrid of glutinosa and minima, which is to be found in the high Monzoni-thal, a "suspended" valley well off the beaten tourist track in the Italian Dolomites, which repays in very full measure the attention of the gardener, botanist and geologist. P. minima is by universal consent not easy of cultivation. As for glutinosa, it is damned by the greatest of rock garden apostles as "not impossible but . . ."—words deterrent to the many, though doubtless an appetiser to the undaunted few, among whom Dr. Macwatt himself finds it "chary of bloom." Yet Florekeana is a free thriver. It is only fair to glutinosa to add that the same apostle bestows on it the highest praise and, apart from eulogy, glutinosa has the distinction of being the only truly blue primula (though in the Monzoni-thal, such has been the interference of minima, you are hard put to it to find many that are "truly blue"). Salisburgensis, again, another of the brilliant offspring of shy glutinosa and capricious minima, is admittedly a free-flowerer. The tale of the hybrid primulas is a long one and with few exceptions they are both easier and of clearer colour than the species. Memory off hand takes me to only one "ugly"—P. discolor, appropriately named.

CAMPANULAS LANATA AND SPECIOSA.

Campanula lanata of the Balkans is described by your Greek correspondent as of a "luminous campanula blue." It was previously given in THE GARDEN as synonymous with C. velutina, with white, yellow or purplish flowers. I have yet to find the hill campanula to which the bald epithet "purplish" does justice. The description of the species reminds one of C. speciosa from the Cevennes and Pyrenees, which Farrer called a "marvel of splendour." The relation between them, if the conjecture of relationship is correct, provides another of the frequent cases in which the elder flora of the Pyrenees jumps over the Western and Central Alps to link itself with that of the Eastern Alps and Balkans, having escaped on either side the havoc of the glacial ages out of which the comparatively "young" mountains of the central chains emerged. E. ENEVER TODD.

A FORECAST OF THE CHELSEA SHOW

TO the lover of flowers, "Chelsea" does not mean a mere district of London, nor does it mean the famous hospital for old soldiers. It spells flowers and scents, catalogues and note-books—and, it must be confessed, crush and bewilderment. Chelsea is looked forward to with eagerness by the garden-loving public of Britain, and it draws visitors from near and far. It is the one floral show which every keen gardener, and others less keen, make a special effort to attend. This year, for five days instead of the customary three, the development and skill of the horticulturist will be demonstrated in Chelsea Hospital grounds from May 19th to May 23rd. These two extra days will enable most visitors to take full advantage of all the opportunities provided by this world-renowned exhibition.

Weather, unfortunately, plays havoc with the plans of many growers. The sun often refuses to shine just when it is most needed, and the cold, drying winds of the spring frequently do much to thwart the best-laid plans. Although it may be true that many of the flowers shown at Chelsea are grown under glass, if the weather is unkind and provides chilly and dull days it is very difficult to produce perfect specimens, and "timing," however carefully done, does not always give the wished-for results.

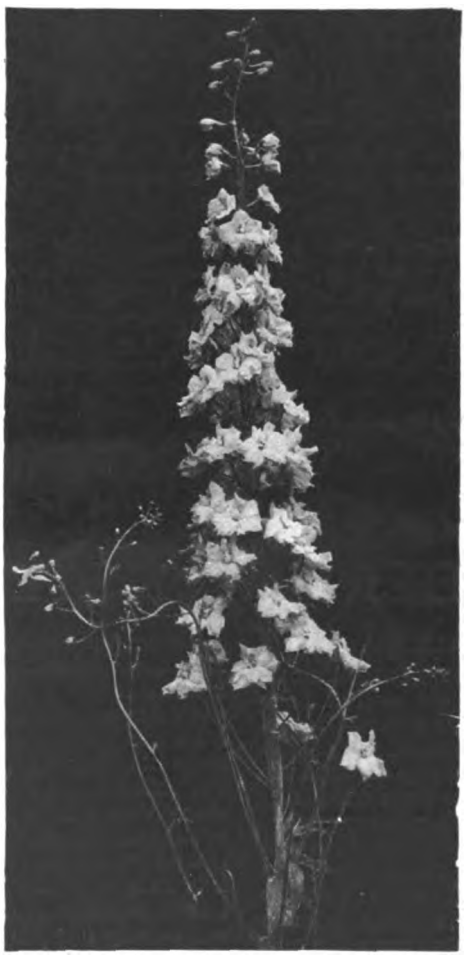
There is every prospect of a very fine Show this year, and the reader should make a point of seeing the exhibits mentioned below. It goes without saying that many others will be well worth attention, but space prevents reference to all when their number is great, if not legion. It must suffice, therefore, if we indicate a few of the exhibits which promise to be particularly interesting.

One of the great advantages of Chelsea is that its size permits of the construction and exhibition of rock and formal gardens of an appreciable size. There is a likelihood of some interesting rock and formal gardens being laid out this year.

Mr. George G. Whitelegg plans to use water-worn Yorkshire limestone in the construction of a rock garden, through which a mountain stream will run. In the little rocks and corners and in the cool water-sprayed crevices, choice alpines will be placed. On the more open spaces, saxifrages both new and rare and some lovely gentians will flourish. Other plants for the rock garden which Mr. G. Whitelegg can supply will be seen on his stand in one of the tents. There, choice alpines in bloom as well as the more ordinary will be exhibited in abundance. Mr. Whitelegg is showing among his collection of irises some of his new seedlings, which are bound to attract attention.

A display of those forms of Cupressus obtusa nana, whose neat and compact habit make them excellent backgrounds for low-growing alpines, will be made by Messrs. W. H. Rogers and Co. Cupressus obtusa tetragona minima, C. obtusa cæspitosa and C. obtusa juniperoides will be included. Among these shrubs, which will be found on a tiny rock garden constructed on one of the tables, there will be patches of primulas, such as P. helodoxa and P. Flambeau, drifts of Campanula muralis major, and groups of meconopsis, Cambrica aurantiaca plena, Iris gracilipes, Oxalis adenophylla and many another beautiful alpine.

Judging from the reputation which is possessed by Messrs. Maxwell and Beale, and from their exhibits at other shows, both the formal garden and the inside rock garden constructed by them should be very interesting. Their plans sound most attractive. In the centre of the formal garden there will be an old West



DELPHINIUM MONARCH OF WALES.

Country well. The square paved paths will be edged with lavender, and the garden will be enclosed by a low wall planted with flowering alpines. A small pool surrounded by masses of spring-flowering rock plants will be found in their inside rockery.

Whether it is wet or fine during Chelsea Week, the rockery made of Westmorland stone and constructed by Messrs. R. Tucker and Sons may be examined in comfort, for it is under cover. It will be planted with alpines, shrubs and herbaceous plants. If this firm is able to equal their gold medal exhibit of last year, it will demand notice.

The alpine specialist will make a point of visiting Mr. W. Wells' exhibit of gentians and choice alpines. If the weather is favourable before the Show, his collection will undoubtedly include some of the best forms.

Another exhibit which the lover of rare alpines should not miss is that of Messrs. Oliver and Hunter. They propose to show many of the hardy primulas, including such species as P. Forrestii, P. pulchella, P. geraniifolia, P. pinnatifida, P. pseudo-capitata and P. Littoniana, giant form. Among other alpines which they will exhibit are Omphalodes Luciliæ, Saxifraga primuloides Farrer's form, Armeria cæspitosa and Meconopsis integrifolia.

Mr. Frederick G. Wood intends to have an inside rock garden. Alpines and shrubs in great variety will adorn the rockery. Daphne Cneorum, Cytisus Beanii, Cistus formosa, and some rock conifers, such as Cupressus Fletcheri, Retinospora gracilis nana and Thuya Reingold, are a few of the shrubs which will be there. Among the alpines will be silvery saxifrages, primulas, aquilegias, Campanula Stevenii, dianthus, erinus and mimulus.

New and uncommon shrubs will be an attractive feature on the stand of Messrs. Hillier and Sons. This firm hope to show their new Cistus Hillieri for the first time. Japanese maples, wistarias, bamboos and azaleas will be well represented.

Messrs. W. H. Gaze and Sons are constructing a terraced garden, in front of which will be a sunk garden. The garden will mainly show the possibilities of treatment of grounds surrounding the house. Messrs. Gaze will also show a selection of garden ornaments.

Messrs. Bakers and Co. will have an original exhibit. It will take the form of a stream garden. Visitors who are the happy possessors of a garden through which a stream runs, or those who may wish to construct an artificial one, should be able to get from this exhibit a number of ideas. There is an art in the design and construction of a stream garden; the right introduction of water will make, the wrong will mar, the whole effect.

Messrs. Cutbush and Co., who are noted for their clipped trees, polyantha roses and azaleas, will have exhibits as varied as their reputation is high. Specimens of their cut bushes will be seen. Salmon Queen, Orange King (two dwarf polyantha roses) and Red Explorer (the new climbing polyantha which evoked much admiration at the Spring Rose Show, will be on view. Hydrangeas, including such varieties as Helge, Lorely, Maréchal Foch, etc., will be shown inside; while it can be prophesied that among the rock gardens the space allotted to Messrs. Cutbush will be attractively filled.

Messrs. J. Carter and Co. are exhibiting a formal garden again this year, and in it there will be a fountain and pool.

Digitized by Google

Under cover of the tents they intend to show florists' flowers in plenty, cinerarias, gloxinias and begonias will be among them. Annuals will also occupy a large portion of the space allotted to this firm.

From Messrs. Barr and Sons, the firm so noted for raising first-class bulbs, one expects great things. At Chelsea, they are going to exhibit a large and varied collection of tulips, including representatives from many of the sections. In addition, they will exhibit irises, early-flowering perennials and certain alpines.

At each fortnightly show of the R.H.S. the exhibits of Messrs. Skelton and Kirby are always noticeable; and at Chelsea they hope to exhibit a similar collection of alpines and shrubs.

Shrubs of all kinds play an important part in the gardens of to-day. In some cases the demand is greater than the supply, and it is useful to know of a reliable firm who have a good stock of the more uncommon shrubs. Messrs. W. Fromow will be exhibiting a varied collection of Japanese maples, including such as Acer dissectum palmatifidum, A. japonicum aureum, A. roseum marginatum, A. Seigenii and A. involutum variegatum.

An interesting collection of rhododendrons and azaleas will be staged by the Dutch firm, Messrs. Koster and Sons.

Each year roses of all kinds are exhibited in great numbers and add to the beauties of the floral exhibits. Messrs. Frank Cant and Co. will be staging a large exhibit of many varieties, including their new seedling roses of the last three years. Among them will be Chastity, Henry Nevard, Blush Queen, Captain F. S. Harvey Cant, Prince Yugala, Snowflake and, lastly, their new pedigree seedling rose, Rosemary, the first batches of which will be ready for distribution from June onwards. Rosemary is the beautiful hybrid tea which was awarded the 100-guinea Clay Challenge Cup for the best seedling rose introduced in 1923 with a real old rose scent.

Mr. Elisha Hicks will have almost a thousand pot roses in his group. Among them there will be all the good varieties, both old and new.

Many rambler and weeping roses will be exhibited by Messrs. A. J. and C. Allen, as well as hybrid tea, hybrid perpetual and tea roses. Havering Rambler, Papa Gouchault, Fernand Rabier, Excelsa, Orange King, the new climbing polyantha Phyllis Bide, and such well known varieties as Golden Emblem, Hadley and Betty Uprichard, will be included in this firm's collection.

A few of the varieties of roses which Messrs. B. R. Cant and Sons intend to exhibit are Rev. F. Page Roberts, Padre, Covent Garden, Casson, and three of their new pedigree seedling roses, Lady Roundway and Sovereign, both pernetianas, and Lady Dixon-Hartland, a hybrid tea.

ROSE SOVEREIGN, A GOOD PERNETIANA.

ONE OF MESSRS. GAZE'S HERBACEOUS BORDERS.

Hosts of hardy flowers, such as delphiniums, lupines, peonies and irises, will be exhibited at Chelsea if the weather is warm enough to bring them on in time. Irises arranged in beds outside are an attractive feature at any show, and Messrs. Bunyard intend to exhibit irises in this way. A table of fruit will be exhibited by this leading fruit firm. On it late-keeping varieties of British apples and pears, such as Ontario, Wagener, Allen's Everlasting, Newton Wonder, Clark's Seedling, Sandling Duchess and the excellent variety Bramley's Seedling as well as many others will be displayed. This will surely cause many fruit growers to cast envious looks in the direction of Messrs. Bunyard's stand.

New varieties of single-flowered pyrethrums, hybrid tree lupines, herbaceous lupines, peonies—including herbaceous, double and single flowered—and new varieties of delphiniums will be staged by the well known firm of Messrs. Kelway and Sons.

Messrs. Blackmore and Langdon hope to exhibit delphiniums and double begonias. Many of the old as well as the new varieties will be included.

Another firm showing delphiniums is Messrs. Hewitt and Co., who will include

Digitized by Google

in their collection the celebrated Wrexham strain of delphiniums, Dutch irises and tulips of all kinds. Among the delphiniums will be The Bishop, Coquette, Joy Bells, Monarch of Wales, and Wembley. They are choosing such irises as Hart Nibbrig, Rembrandt, Hemskirk and J. P. Seegers to exhibit.

The multi-colours of St. Brigid anemones will form a vivid patch of colour in the beds which Messrs. Reamsbottom and Co. intend to fill with these beautiful and popular flowers.

Messrs. Stuart Low and Co. will have flowers of all kinds to display before the public. The main sections can be divided into carnations, roses, greenhouse plants and orchids. Among the fifty varieties which make up the carnation group will be Sir Philip Sassoon, Lady Hindlip, Mauve Queen and Eileen Low, all of which have been seen at the recent meetings at Vincent Square. The much talked-of rose, Roselandia, and another rose novelty, called Rosamond will be there. Acacias, ericas, boronias and many other greenhouse plants will be selected by Messrs. Stuart Low and Co. to form a large group.

Messrs. Allwood Bros. plan to stage an exceedingly large exhibit of carnations of all kinds. Some novelties which they will be showing are Shot Silk, Cameron, Butterfly and Master Michael Stoop. Jane, Anne and Roger, three Allwoodii novelties, will be exhibited.

Perpetual carnations in all shades will be staged by Messrs. Keith Luxford and Co.

Messrs. C. Engelmann, Limited, are exhibiting a large group of carnations, including a number of new unnamed seedlings. Two varieties, Red Laddie and Canada, will be worth noting.

Mr. James Douglas will be exhibiting Douglas cloves and hardy border carnations and, in another group, auriculas will be seen. These fragrant clove carnations are quite hardy, and such varieties as Salmon Clove, White Clove, Bookham Clove and Queen of the Cloves, which Mr. Douglas will show, all form well shaped flowers.

Messrs. Alex. Dickson and Sons with their famous Hawlmark sweet peas, should make a striking effect at Chelsea. They are arranging them in a novel way. At the back of the stand the flowers will cover a large trellis-work, and in front Elegance, Hawlmark Pink, Powerscourt, etc., will form bold groups of contrasting colours.

Each Chelsea Show brings forth some novelties in sweet peas, and Messrs. Dobbie and Co. hope to add several more to the ever-increasing list of varieties. In tulips, too, they have a number of surprises in store for the visitor.

Bulbous flowers, such as Darwin and late-flowering tulips, irises and gladioli have been selected by Messrs. R. H. Bath, Limited, for their exhibit.

Sunshine is what Messrs. Austin and McAslan need, or else the tulips which they hope to exhibit will not be in flower in time for the Show.

Messrs. W. H. Simpson and Sons will be exhibiting many varieties of antirrhinums.

Many species of odontoglossums, miltonias, odontonias and cypripediums will comprise the exhibit of orchids staged by Messrs. Charlesworth and Co.

Messrs. Laxton Brothers are introducing three new strawberries which will be seen on their exhibit at Chelsea. The new varieties are Empress, Vicomtesse and Laxton's Rearguard.

From Perry's Hardy Plant Farm there will be an interesting collection of new and rare ferns.

Messrs. G. Jackman will be exhibiting a large group of the leading varieties of clematis.

A great variety of lupins in all shades including many recent introductions, will be staged by Mr. G. R. Downer.

Many kinds of flowering plants raised from seed will form the exhibit of Messrs. Webb and Sons. Cinerarias, including Cineraria stellata and the cactus-flowered cineraria, calceolarias, tuberous-rooted double begonias, giant hybrid schizanthus, and countless annuals in pots, will be staged by this firm.

With good weather from now onwards, Chelsea should be a most successful and interesting Show.

WALLFLOWERS

IN the scheme of what is generally known as spring bedding, wallflowers play an important part, and to have really fine bushy plants by the autumn the seeds ought to be sown during the month of May. The chief cause of failure with these delightful plants is late sowing, and although some may say July is sufficiently early, I maintain that fine examples cannot be obtained in the time, *viz.*, sturdy bushy plants in October or early November. Select an open site, and one that is not too rich. Sow the seeds thinly in drills 1ft. apart, and if the soil is dry afford the lines a thorough watering a few hours before sowing the seeds. Directly they are through the ground, use the hoe occasionally, then the seedlings will make headway.

Transplant early, before the young plants become drawn and leggy, and when they are about 2ins. high they should be set out in rows 1ft. apart, the same distance being allowed between the plants. Make the plants secure, and give a good watering; then, if the weather is favourable, no more will be needed.

During the summer months, keep down the weeds by frequent use of the hoe. When the plants become established, pinch out the centres to produce side shoots, and the beginner ought to bear in mind that no further pinching is needed. Wallflowers deserve an open situation during their growing period.

With the arrival of autumn and dull days, when the beds are cleared of their summer occupants, it gives great satisfaction to know there is a fine batch of wallflowers to draw from to fill up the void, and, moreover, the hardy, easily grown wallflower is among the best of our spring flowers.

Although there is a number of varieties to choose from, the following can be strongly recommended. For early-flowering, the various forms of Phœnix should be chosen, and, if the weather is mild, it is more or less in bloom throughout the winter. The blood-red and yellow Phœnix are both useful. Among the later flowering kinds will be found Fire King, a vivid orange, and seen at a distance the colour appears to be almost scarlet. I noticed this fact particularly last year. A suitable companion to Fire King is Orange Bedder: it is a rich orange when first open, but changes with age to apricot yellow. Cloth of Gold is a bright yellow, and when associated with Royal Blue forget-me-nots is most effective. Everyone enjoys a good strain of the Blood Red wallflower, and it is well nigh indispensable.

Primrose Monarch is a pale yellow variety and one I do not care for, and the same remark applies to Miss Willmott, described as pure bright ruby, but miserably dull when compared with the kinds quoted above.

THE SIBERIAN WALLFLOWER.

This plant, Cheiranthus Allionii, grows from 9ins. to 12ins. high, and produces flowers of a bright orange colour. It may be sown at the same time as other wallflowers, and a large patch in the border is sure to attract considerable attention. It is not met with so frequently as its merits deserve.

CHEIRANTHUS KEWENSIS.

Often described as half-hardy, this hybrid wallflower is never given any protection in the district of Chepstow, Mon., and it produces a fine display when other members of the family are over. The flowers open a pretty shade of primrose and change to mauve. With age the plants become somewhat leggy and untidy in appearance, but I find the best method is to raise seedlings annually, and dispense with the old plants after flowering. It is suitable for pot culture in a cool greenhouse.

WALLFLOWERS FROM CUTTTINGS.

A favourite of mine is the perennial old-world double wallflower, Harpur Crewe. It is a rich gold, about 12ins. high, and is very fragrant, somewhat resembling mignonette. Another single-flowered plant is Marshallii, a brilliant orange hybrid 9ins. to 12ins. high, but is not often seen in gardens. Both these plants are increased by cuttings, which will readily form roots about August if placed in sandy soil in a hand-light or cold frame. T. W. BRISCOE.

CONSERVATORY AND GREENHOUSE

THYRSACANTHUS RUTILANS.—This beautiful plant is generally regarded as being suitable only for the stove; it, however, develops its flowers perfectly in a warm greenhouse where the night temperature is kept at about 50° Fahr., producing its long drooping racemes of red flowers during March and April. Like many other plants of this class it should be grown in a temperature of about 60° Fahr. while it is making its growth, removing it to a cooler house for flowering.

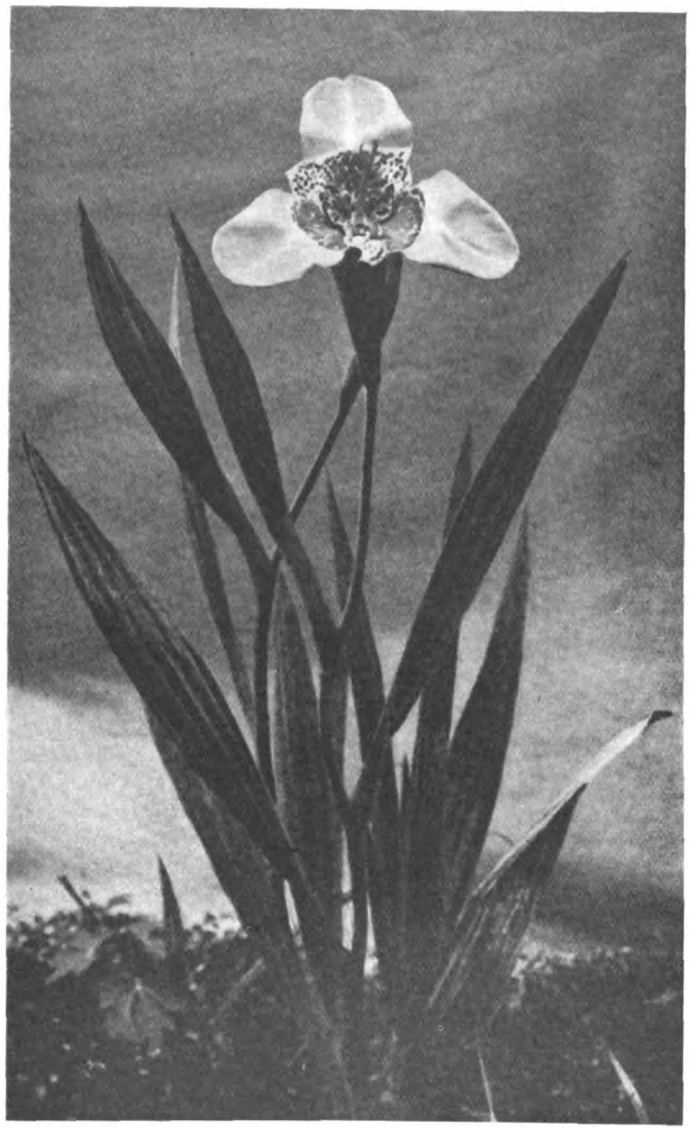
The cuttings, which root readily in a warm propagating case, are best inserted singly in small pots about the beginning of May. The young plants should not be pinched, as it is desirable that they be as tall as possible for the proper display of the long drooping inflorescences; for this reason it is desirable to grow some of the plants on for the second year. During the first year good examples can be produced in 5in. pots. The plant grows freely in a compost of good medium loam, with the addition of some leaf-soil and sand, the proportions of leaf-soil and sand varying according to the character of the loam.

TIGRIDIA PAVONIA (Mexican tiger flower), of which there are several varieties, is hardy during the summer in warm situations in the South and West; in colder parts of the country it requires the shelter of a cool house, and it is surprising that it is not more generally grown in this way. Although the flowers are very fugacious, they are produced in succession over a long period. The dry bulbs can generally be purchased during autumn and winter, and may be potted during March and April.

They grow freely in any good, well drained potting compost. Five or six bulbs should be placed in 6in. or 7in. pots; these should be placed in cold frames or in a cool greenhouse, and water should be very sparingly afforded until the bulbs have started into growth and made a quantity of roots.

ERYTHRINA CRISTA-GALLI.—This plant is very useful for conservatory decoration during the summer months. Plants that have been stored dry all winter should now be started into growth in a cool house. After getting a good soaking at the root they soon start into growth. If it is desired to increase the stock, young shoots should be secured as cuttings when they are about 3ins. to 4ins. in length. These should be cut off at the base from the old root-stock, and if inserted in light sandy soil they soon root in a close propagating case. Young stock can also be raised from seeds.

Until they are some three years old and have made a good woody root-stock, they should not be dried off too much during the winter, as they get shrivelled and fail to start into growth. Large specimens when in full flower are very handsome, with their dark red, lobster-claw-like flowers.



TIGRIDIA PAVONIA, NOTE THE TIGER'S HEAD IN THE FLOWER.

HUMEA ELEGANS should now be ready for placing in their flowering pots, which, according to the strength of the plants, may be 8ins. or 10ins. in size. This plant is generally regarded—and not without reason—as being somewhat difficult to grow successfully. Provided it is grown perfectly cool it should give little or no trouble in its younger stages; but, unless care be exercised during the final potting, trouble may be expected at this stage. Water should be carefully afforded at the root until the plants have got a good hold of the fresh compost.

Humeas are subject to attacks of green and white fly; they are also very susceptible to injury from fumigation and the use of insecticides but I find they suffer no injury from fumigation with hydrocyanic acid gas, using ¼oz. of sodium cyanide per 1,000 cubic ft. Of course, the safety factor depends very largely on the plants being fairly dry at the root, and also on the house being at the proper temperature.

LISIANTHUS RUSSELLIANUS.—This handsome plant, like many others belonging to the natural order Gentianeæ, has the reputation of being one of the most difficult plants to cultivate successfully. It is, however, so beautiful that it is well worth some extra trouble with a view to bringing it to perfection.

It is quite easily raised from seed, which is very fine and should be covered with just a sprinkling of sand. The seed pot should be covered with a piece of glass and be kept shaded until germination takes place. Most cultivators when dealing with this plant make the mistake of sowing it too early. Seed is best sown about the middle of May, the aim being to get a sturdy rosette of leaves developed before winter. If sown too early, the plants will probably make an attempt to flower during the autumn and thus weaken the plants for next year.

They are best wintered in a small house or pit in a temperature of 45° to 50° Fahr., watering them very carefully at all times. Having got them safely over the winter, and when they have started to make fresh growth in early spring, they should be placed in their flowering pots, which may be 5in. or 6in. according to the size of the plants. The compost should consist of good medium mellow loam, with the addition of some fibrous peat or flaky leaf-soil, and enough sand and some charcoal to keep the whole open and porous. Water must be very carefully afforded at all times. This plant is also somewhat subject to attacks from thrips, which must be guarded against.

LOBELIA TENUIOR is very useful for greenhouse decoration during summer and autumn. For this purpose successional batches should be sown in a temperature of about 50° Fahr. When fit to handle, the young seedlings should be pricked off into small pots, putting four or five plants in a pot. As it becomes necessary they should be potted on until they are in their flowering pots.

J. COUTTS.

RHODODENDRONS AT VINCENT SQUARE

CONSIDERING the backward season, the collections of rhododendron blooms which constituted the main section of the Show at Vincent Square on May 5th and 6th were remarkably fine. This is one of the few plants in the showing of which amateurs predominate, and well they may, for it is mostly owing to the enthusiasm of a small and select band of amateurs that the rhododendron has achieved its present popularity. Apart from the criticism about the number of hybrids, which is dealt with in this week's Editorial, the only fault that could be found with the exhibits was that in many cases they were overcrowded owing to shortage of space. This made the picking out of individual plants a matter of some difficulty—that and the general excellence of the exhibits.

Mr. Lowinsky year by year stages a wonderful show of his fine hybrids, many of which are only suitable for indoor cultivation. This successful hybridiser has now achieved such a general degree of excellence that it is next to impossible to pick out a plant which excels its neighbour. In our opinion, however, the finest plant in his exhibit was R. Wightii, an old Himalayan species with creamy yellow bell-shaped flowers, blotched with deep crimson at the base. Undoubtedly Mr. Lowinsky possesses the best form in cultivation.

Lady Aberconway and the Hon. Harry MacLaren exhibited a fine representative collection of many of the best species and hybrids in cultivation, among them Thomsoni × Kewense, which is of a finer and deeper shade of rose than the commoner Thomsoni × Fortunei. On either end of this exhibit were fine vases of R. Augustinii of a good shade of blue-lilac, and R. Benthamianum, a purple triflorum from Szechuan and, for some reason or another, a rare plant in cultivation.

Mr. Lionel de Rothschild's exhibit was most noticeable for the big vase of R. Loderi which grows so well at Exbury. Probably every gardener will envy him for his form of R. campanulatum, Knap Hill variety, for which he obtained an award of merit. This is the cream of all campanulatums, with its rich lilac blooms. Another fine hybrid was to be seen on this stand—R. Thomsoni × Mangles Scarlet; this is far darker than the ordinary R. Thomsoni and has the rich appearance of a ripe plum.

Lieut.-Colonel Messel showed species and hybrids of excellent quality, among them a fine old pink arboreum called No. 1, which is the parent of many of the arboreum hybrids now in existence, and also a fine form of white arboreum. This exhibit was noticeable for the fine vases of Acacia verticillata. This was grown in a cool house, and is, without a doubt, one of the finest subjects for indoor decoration that we possess.

Mr. E. J. P. Magor's exhibit was noticeable for the finest blooms of R. Augustinii at the Show. This rhododendron is most variable in colour, but without a doubt Mr. Magor possesses one of the best forms in cultivation. It is as near blue as any rhododendron, and has a cool tint about it that is charming. He also showed R. salwenense, a dwarf with large open purple flowers that will look particularly well planted in a mass in the rock garden.

Among the many rhododendrons on Colonel Stephenson Clarke's stand was a hybrid of Griffithianum and campylocarpum, aptly named Pelican. This had a large shapely truss of cream-tinted flowers with crimson at the base spreading up the throat. This is a fine hybrid, and it is hoped that it will be distributed in time. It was also pleasant to see Ivory's Scarlet, an old favourite and still one of the best reds in the garden.

Sir John Ramsden showed many fine species and hybrids, among them the Duchess of Portland, very old but probably the best white hybrid in cultivation; and Gloriana, a very fine red cross between campylocarpum and barbatum. In the original cross there are few signs of campylocarpum, but seedlings of this plant are showing a distinct throwback to campylocarpum, which only proves the difficulty of guessing at the parentage of hybrids.

THE DEEP CRIMSON FLOWERS OF R. SPERABILE (FARRER 888).

Mr. Gerald Loder staged a most interesting collection of species and a few hybrids. Among the most noticeable were R. diphrocalyx, a red rhododendron with a split and most uneven calyx of the same shade as the petals, and a rhododendron named argyrophyllum. This rhododendron usually flowers in March and has a more decided tomentum on the undersurface of the leaf, but whatever it may be, it was distinctly attractive with bell-shaped trusses of a good pink.

Among the trade, Mr. Reuthe showed his usual fine assortment of hybrids and species, mostly hardy. Messrs. Gill, on the other hand, staged species and hybrids most of which will only grow out of doors in the mild West. Two of these are noticed in the plants which obtained awards.

Among Messrs. Veitch's stand of hybrids and species was a vase of Cunningham's Sulphur, that all-yellow rhododendron with caucasicum blood in it that was so nearly lost to cultivation a few years ago. It is pleasant to hear that this fine plant is again on the market in quantity. Messrs. C. B. van Nes of Boskoop showed several of their famous strain of hardy hybrids which are among the best in cultivation, among them The Unknown Warrior, a fine deep rose. They also staged an azalea which is noticed among the awards.

An interesting group, composed entirely of a new strain of Primula pulverulenta, was exhibited by Mr. G. H. Dalrymple. He was showing P. pulverulenta Lady Thursby and P. pulverulenta pink seedlings, both of which have been raised by him. P. pulverulenta Lady Thursby is not a hybrid. It is a true P. pulverulenta. The flowers are a soft, crushed strawberry pink, and are borne in three or four whorls on thick, stiff stems. The seedlings of P. pulverulenta were very similar, but the flowers were paler in colour, and some had a slightly darker eye.

The most brilliant picture among the alpines was a great drift of gentianella, shown by Clarence Elliott, round a solitary mountain of grey limestone, capped with a snowy patch of a very large-flowered and vigorous form of Androsace arachnoidea. At the foot of the mountain on the north side were a few plants of the rare Gentiana pyrenaica, with deep-throated little flowers of rich violet blue, which have been recently described in THE GARDEN. Dotted about in the sea of gentians was Sisyrinchium filifolium, which shows off its silky white flowers with their delicate purple veining by carrying them nearly upright, instead of dangling them like S. grandiflorum, and is easily the finest of its family, though at present the rarest. Mr. Wells, Junr., demonstrated this in another way, by showing a few clumps of his form of gentianella (obtained many years ago from an old garden), which were covered with buds and flowers.

Maurice Prichard showed several very interesting plants; Arenaria verna, a rare native that is not very showy, but makes a close turf, spangled with little white flowers, that serves as a perfect background for other small plants that like company; Haberlea virginalis, the white form, H. Rhodopensis, whose cold, alabaster flowers are even more exquisite than the lavender gloxinias of the type; Anemone sylvestris Baikalensis, a beautiful plant with a doubtful name, that seems identical with the large, free-flowering form of A. sylvestris, in the large creamy white flowers, with their tassel of soft yellow stamens in the centre.

Mr. Frederick Wood showed a vigorous form of Primula chionantha, whose tiers of white flowers, touched with grey and green about the calyx, stood out interestingly against the dusty purple background of a group of Muscari paradoxus; the white variety of Viola cucullata, with fine solid flowers, set off by neat black whiskers and a good form of the Hose-in-Hose cowslip from Ireland, named Erin's Gem, in which each of the flowers is almost completely reduplicated.

Digitized by Google

W. Wells, Junr., showed the double Marsh Marigold, a quaintly formal, old-fashioned flower that associates well with the double Lady's Smock; Linaria æquitriloba the microscopic snapdragon, and the rich golden saucers of Geum montanum.

Messrs. Bakers of Wolverhampton exhibited some unusual primulas; P. anisodora, which is very nearly ugly, with black buds and mahogany-coloured flowers, but made an amusing contrast with the prim innocence of Ranunculus amplexicaulis: Primula secundiflora, whose large drooping bells, deep pink outside and purplish crimson inside, are covered with a grey bloom.

Tucker and Sons of Oxford showed Ranunculus Seguieri, the beautiful white equivalent on the limestone of R. glacialis.

Among other exhibits were the following:

ANEMONES.—Messrs. R. Gill and Sons and Reamsbottom and Co.

CARNATIONS.—Messrs. Allwood Bros., C. Engelmann and Stuart Low and Co.

CLEMATIS.—Messrs. L. R. Russell and Co.

DAHLIAS.—Messrs. J. Cheal and Sons.

GREENHOUSE PLANTS.—Messrs. L. R. Russell and Co. and Stuart Low and Co.

HYDRANGEAS.—Messrs. R. and C. Cuthbert.

NARCISSI.—Messrs. Barr and Sons, J. W. Barr and R. H. Bath.

PELARGONIUMS.—Messrs. Jarman and Co.

POLYANTHUS.—Messrs. John and A. H. Crook and G. A. Miller.

ROSES.—Messrs. Benj. R. Cant and Sons, Elisha Hicks and J. H. Pemberton.

SHRUBS.—Messrs. Cheal and Sons and R. C. Notcutt.

SHRUBS AND ALPINES.—Carter Page, K. and E. Hopkins, B. Ladham, Skelton and Kirby, W. H. Rogers, Waterers.

TULIPS.—Messrs. Barr and Sons and R. H. Bath.

VIOLAS.—Messrs. Carter Page and Jarman and Co.

AN INTERESTING GROUP OF PRIMULA PULVERULENTA LADY THURSBY.

NEW AND RARE PLANTS.

AZALEA HOLLANDIA, a hardy seedling azalea, Hinodegiri × Kæmpferi, showing obvious signs of its parentage. Good rose and brick red colours and very floriferous. A fine addition to our hardy azaleas. Award of merit. Messrs. C. B. van Nes, Boskoop, Holland.

RHODODENDRON WILLIAM WATSON, foliage light green, flowers whitish pink in colour, petals spreading, about 3ins. in diameter; Aucklandii blood. Award of merit. R. Gill and Son, Falmouth.

R. TEYSMANII.—A species found in Sumatra, with good foliage, slightly hairy, but no tomentum; flowers are like a large javanicum, three to a truss, white, 4ins. in diameter, and a tube 4ins. long. Should be a valuable addition to our hot-house rhododendrons. First-class certificate. Messrs. R. Gill and Son, Falmouth.

R. DOROTHEA.—A hybrid, carrying a good truss of flowers 4–5ins. across, of a delicate pale pink shade, with slight spotting on petals and pink deepening in tone towards the edge. Foliage long, of a pale dull green. Award of merit. Mr. T. H. Lowinsky, Sunninghill.

R. SPERABILE (Farrer 888).—A species which grows to about 6ft. in height. Whole plant is hairy, and the undersurface of the leaves is very woolly. It carries a good close truss of a fine shade of deep crimson. A valuable acquisition. Award of merit. Mr. L. de Rothschild, Southampton.

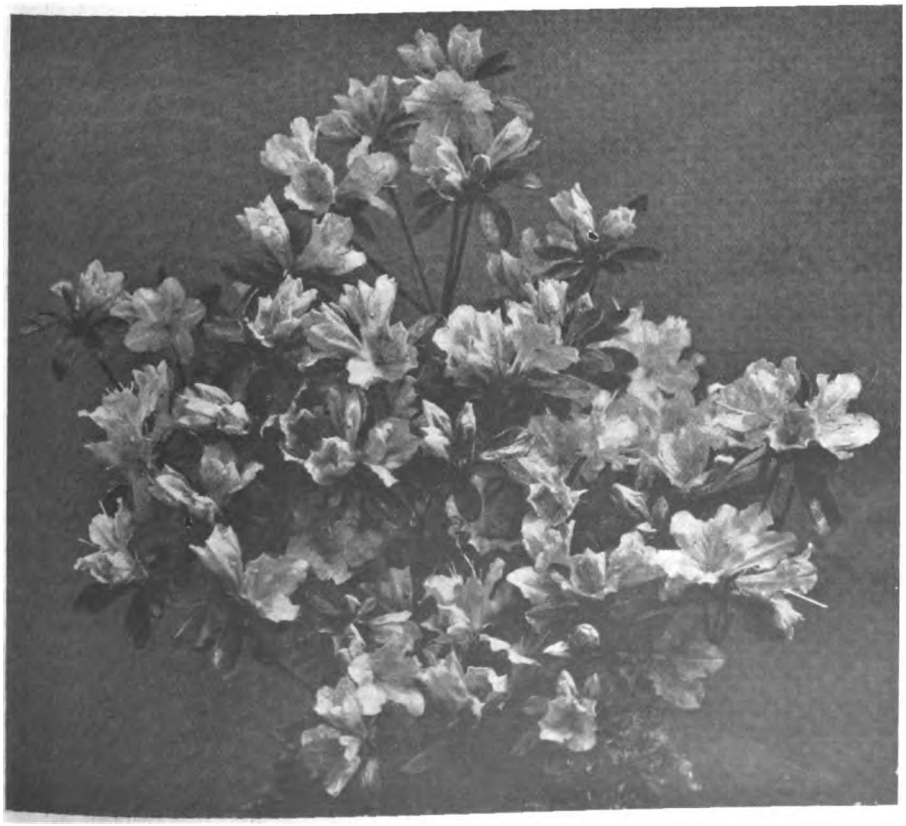
R. CAMPANULATUM KNAP HILL VAR.—A very fine campanulatum, carrying loose trusses of bluish-lilac flowers blotched at the base and with spots on the petals of a deep wine colour. Award of merit. Mr. L. de Rothschild, Southampton.

ACER PSEUDO-PLATANUS VAR. BRILLIANTISSIMUM.—This is one of the many varieties of the common sycamore. It is, however, an exceedingly handsome one, as was seen by the branches shown, bearing leaves of a beautiful pinkish to coppery hue on unfolding. In addition, the foliage has a pleasant sheen which is decidedly characteristic. Shown by the Hon. Vicary Gibbs, Aldenham, Elstree.

RETINOSPORA PLUMOSA NANA COMPRESSA.—This variety has arisen as a sport from the type species Retinospora plumosa. It forms a dwarf, dense, bushy plant more or less conical in shape. The branches are crowded and even overlapping. The leaves are soft and awl-shaped, and are glaucous green in colour It forms an excellent little pot plant and should prove admirable for out-of-door decoration, as it is absolutely hardy. Award of merit. Shown by Messrs. C. B. van Nes, Boskoop, Holland.

ROSE SYLVIA.—Another useful hybrid tea variety to be added to our ever increasing list. It is well supplied with long, good stems bearing large dull green leaves. The blooms are large, of good shape in all stages of growth, and are rose-pink in colour, with a slight fragrance. It is a variety which should prove popular in the garden. Award of merit. Shown by Mr. Walter Stevens, Hoddesdon.

ANEMONE HORTENSIS BLUE GOWN.—This is a charming and dainty variety of hortensis, bearing large double flowers of a lilac-blue



A FINE HARDY SEEDLING AZALEA, A. HOLLANDIA (A. HINODEGIRI A. KÆMPFERI).

Digitized by Google

colour on stems from 6–8ins. high. The colour is good and the form of the bloom perfect. It is a variety which should be cultivated with ease and success in warm dry borders or in rock gardens.

SENECIO BEAUTY OF CAMBRIDGE.—A really fine variety forming an excellent pot plant for indoor decoration, reaching almost 2ft. in height and bearing numerous flowers from 1–1½ins. across. In colour the petals are white with a tinge of blue at the tips. The foliage is also good, and provides a pleasant contrast. Award of merit. Shown by The Director, Botanic Gardens, Cambridge.

NARCISSUS MOROCCO.—This is a handsome Barrii variety with a white perianth. The blooms are large, of perfect shape and substance, and are carried well on long stems. The cupped corona is of a fiery orange shade tinged with red. Award of merit. Shown by Messrs. Herbert Chapman, Limited, Rye.

NARCISSUS MRS. JOHN ROBINSON.—An excellent Poeticus variety with well formed and regular blooms with a white perianth, while the cupped corona is deep yellow margined with orange. The flowers are also well carried on long erect stems. Award of merit. Shown by Mr. John Robinson, Kingswood, Bawtry, Yorks.

ORCHIDS.

ODONTOGLOSSUM WHITE ADMIRAL.—Although of unrecorded parentage, this fine acquisition partakes much of the habit of a grand form of Odontoglossum crispum, the labellum being practically the only segment in which hybrid origin can be detected, and this suggesting that O. Pescatorei has been used in its making. The spike bore ten large flowers, with all the segments broadly developed and of unusually thick texture. The only colour is a slight rose tinge on the two lateral sepals, and a rich crimson-coloured blotch on the labellum near the apex of the crest. First-class certificate. Exhibited by Lieut.-Colonel Sir George Holford, K.C.V.O., Westonbirt, Tetbury, Glos.

MILTONIA PRINCESS MARY, STAMPERLAND VARIETY (M. Hyeana × M. Bleuana var. Reine Elisabeth).—This pleasing hybrid carried a spike of five large flowers, the sepals flushed with crimson-rose, the petals to a much deeper tone, the labellum bears a brownish mask on its basal area. Award of merit. Shown by Mr. Robert Paterson, Stamperland, Cathcart, Glasgow.

ODONTOGLOSSUM ELDORADO (eximium × Lakinæ).—A showy hybrid with a spike of seven large flowers, fleshy in character, and with the segments symmetrically marked with reddish brown, the labellum has a spiny crest of yellow colour. Award of merit. From Messrs. Stuart Low and Co., Jarvisbrook, Sussex.

ODONTOGLOSSUM FABIA VAR. SIR CHRISTOPHER WREN (Aglaon × eximium).—A useful addition to the red section, the present example having a spike of eight moderate-sized flowers of crimson-red colour, a very narrow white margin to all the segments adding to its attraction. Award of merit. Shown by Mr. J. J. Bolton, Claygate, Surrey.

SOPHRO-LÆLIO-CATTLEYA ST. GOTHARD (Sophronitis grandiflora × L.-C. St. Gothard).—A remarkable result in which the influence of the former parent is strongly visible. Although not of large size, the colour is blood red, equally suffused throughout all the segments, thus showing a marked improvement on previous hybrids in this section. Award of merit. Exhibited by Mr. J. J. Bolton, Claygate, Surrey.

EULOPHIA STREPTOPETALA.—Two vigorous specimens of this species from British East Africa were shown by Mr. Wm. Van de Weyer, Clyffe House, Dorchester. The tall and erect spikes each bore upwards of thirty flowers and buds, the rich yellow colour of the petals and labellum being the attractive feature. Cultural commendation.

THE AURICULA SHOW

THE annual show of the Southern Section of the National Primula and Auricula Society, which was held in conjunction with the R.H.S. meeting, was a very small affair, and had the exhibits of Mr. James Douglas been absent there would have been so little left that it could easily have been overlooked altogether.

It seems a pity that the old time interest in auriculas appears to be moribund, because they are very beautiful flowers and deserving of a much wider cultivation. True, the show varieties are somewhat difficult and hard to please, but success with them amply repays the necessary care and attention.

The twelve alpines for which Mr. Douglas was awarded the first prize included Day Dream, Angus, Roxburgh, Hector, The Laird, Purple Alpine and Admiration, and these were a good selection of the different colours. His dozen fancies were also of high quality and a representative selection would include Bronze 3 X, May Day, Pale Yellow, Prospero, Agnes, Maize and King of the Yellows.

The best six, in the first section, were shown by Mr. J. Stanbridge, Tottenham, while Mr. Ed. Heron-Allen, Selsey Hill, had the next four, and was also first with six alpines in the tyro's class, with highly creditable plants. Mr. J. T. Bennett Poe, had the best six alpines, and Mrs. Groves was first with four, and with six in the small growers' class.

Premier cards were awarded to Mr. Douglas for Green Parrot, a striking green-edged show variety, and to May Day, a most lovely rosy lilac Fancy. With Phyllis Douglas, a large purple flower with a velvety maroon sheen, Mrs. Groves won the alpine card.

Mr. G. W. Miller was the only exhibitor of primroses and polyanthuses, along with auriculas, and was awarded all the first prizes.

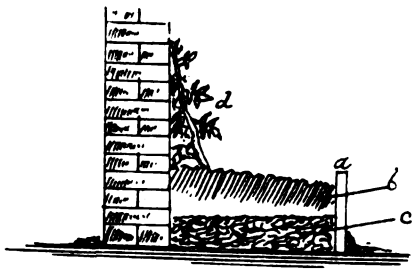
SIMPLE GARDENING

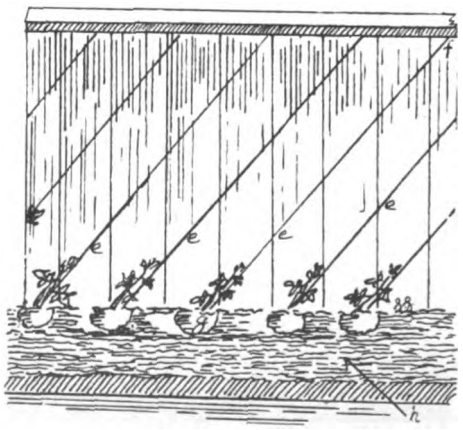
GLOXINIAS.

IN days long gone these plants were subjected to rather high temperatures; in fact, they were treated almost throughout their growing stages as stove subjects. Many amateurs are still under the impression that great heat is necessary to their successful cultivation; and, not possessing the means to provide such artificial heat, they do not attempt to grow the plants. There need not be any hesitation in the matter. Although it is not advisable to grow the plants in cold frames generally, I may say I have seen splendid batches of them in frames during the summer months. Young plants, raised from seeds sown in February, will flower from mid-August to early October; and bulbs started in a gentle heat at the same time will begin flowering early in June; thus we have, by growing both kinds of plants, flowers from June to October. The seedlings like a light loam, porous, with a tiny addition of peat or leaf-soil. At the final potting some well rotted manure will do a lot of good. Rotted manure and bone-meal may be included in the compost for the bulbs except in that in which they were started. At present the ideal position for the plants is one on a bed of ashes on a stage in a greenhouse.

PLANTING TOMATOES OUTSIDE.

This note and the sketches are intended to be helpful to those persons who wish





to grow a few plants outside and have not had any previous experience or who possess poor accommodation for the purpose. In many back gardens and also in small villa gardens there are fences or walls suitable for training the plants on, but not any borders. In such positions, nice, strong plants will, with ordinary care, yield a good average crop of fruit. The plants are not safe from frost outside before the second week in June, unless some temporary protection can be given. In the meantime, the soil should be prepared—good, fibrous, lumpy loam, a small quantity of leaf-soil and a handful of bone-meal to each bushel. Place 9in. boards on edge, or bricks, slates or tiles, shown at *a*, 18ins. from the wall; *b*, finer compost; *c*, roughest parts; *d*, the plants which should be 9ins. or 1ft. high and sturdy. On low fences, train the plants, *e*, *e*, *e*, as shown from *f* to *g*; the border prepared being shown at *h*.

ROSES UNDER GLASS.

We all love roses and are eager to grow plants that will bear blooms as early and as late as possible. It is seldom that the amateur can spare a house solely for roses, so that he decides to plant one or more in a greenhouse or conservatory which contains a miscellaneous collection of plants. My first experience of roses under glass was of Souvenir d'un Ami and Maréchal Niel. One specimen of the first-named, planted thirty years ago, still occupies the same position and flowers—moderately now—

Digitized by Google

every year. The chief difficulty met with is that of affording the plants proper treatment after the spring-flowering stage is passed. A thorough syringing with clear water does good, and also the admission of as much air as possible. When the new summer shoots begin to grow, cold draughts must be avoided or mildew will spread rapidly. Over-dryness of soil is harmful, as is also a too sodden state. Danger of the former exists when the border is small and in a warm position; the latter when the roots permeate soil under stages. Where possible, it is better to have the roots in outside borders. The mildew fungus may be kept under control by the judicious use of soft soap and sulphur or "Abol." Fumigation will keep down green aphides.

RE-POTTING TREE CARNATIONS.

The final re-potting of these plants will claim the attention of lovers of the flowers. To my knowledge, inexperienced cultivators subject the plants either to too much heat or expose them to a too low temperature. After the plants are well established in 5in. pots there should not be any undue delay in shifting them to the final ones, 6½ins. or 7½ins. across. Larger pots for single plants are not desirable. From the third week in June to the end of August, amateur cultivators would manage their plants better on a bed of ashes in a sheltered position outside than in a greenhouse. Good fibrous loam in which all grass has been dead at least one month should form the body of the compost. Take a bushel of loam as a guide; add to it a 6in. potful of leaf-soil, a 3in. potful of bone-meal, a 5in. potful of wood ashes and a similar quantity of well pounded bricks—old ones reduced to small bits—and a very good compost will be available. Before potting work is done the soil in the smaller ones should be examined and watered at least one hour before re-potting. It is not wise to shift the plants to larger pots while the soil is very dry or in a sodden condition. After potting the plants, place them under glass again and spray the foliage, but do not water the soil for one or two days; then fill up the pots with clear water and afterwards when it is required, so that the roots do not get too dry. Wait until the pots are fairly well filled with roots before applying stimulants.

GEORGE GARNER.

NOTES FROM CONTRIBUTORS

PRIMULA WINTERI.

ALTHOUGH it is a good number of years since this charming Himalayan primrose was first introduced to cultivation, it is surprising it is not more often met with in different gardens throughout the country. This lovely plant inhabits the higher Alps and was discovered at an elevation of 12,000ft. It is therefore hardy in most parts of this country, in spite of our changeable climate. To grow it successfully in the rock garden, select a cool northern position, which must be thoroughly drained. The compost may consist of 2 parts of fibrous loam and 1 part each of leaf-soil and sand, with the addition of a little lime rubble (which the majority of primulas enjoy).

In districts where the rainfall is excessive, abundance of gritty sand must be used in the mixture, and especially round the collar of the plants. Unfortunately, the flowers of this alpine gem are often spoiled out of doors, flowering as it does during February and March. Should this be the case, it may be grown in pots or pans in a cold greenhouse or frame. It is an ideal subject for this purpose, and the flowers usually develop to perfection, as shown in the illustration. They are about the size of the common wild primrose, but are of a most beautiful delicate lavender-blue shade, with distinct zone of white round the conspicuous yellow eye, the edges of the petals being sharply serrated. The whole plant is freely powdered with white farina, which enhances the lovely colouring of the flowers to perfection. During the summer, plants that are grown in pots or pans are greatly improved by being plunged in ashes out of doors, and shaded during the hottest part of the day and liberally supplied with water. In the autumn they should be transferred to the cold frame or greenhouse again.

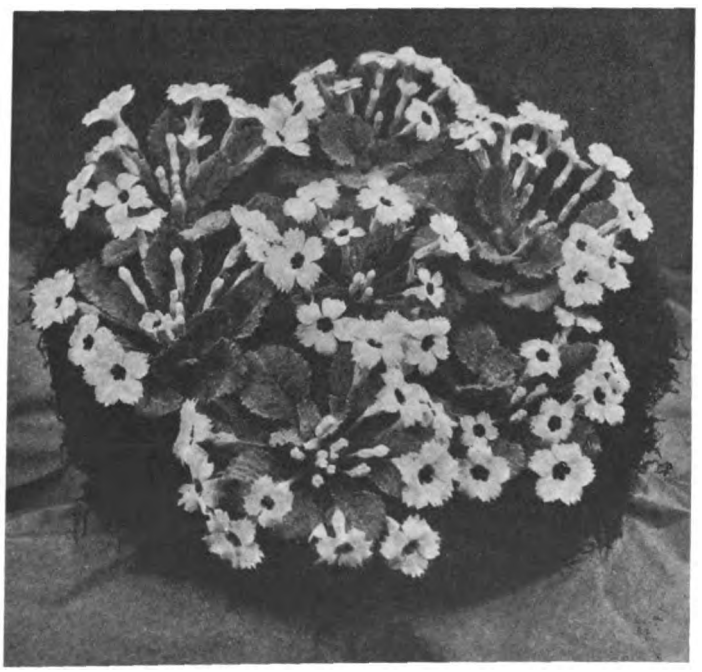
Primula Winteri is increased by seed when procurable, but appears to be a shy bearer in cultivation. It may also be divided when the plants show two or three crowns; this method may be done shortly after flowering, employing the same mixture of soil as already recommended for the rock garden. This charming species is worth any amount of trouble, due attention should be given to those small details.—GLENCAIRN.

ICELAND POPPIES.

THE Iceland poppy is not difficult to rear from seed, which may be sown in the early spring where required to grow, and afterwards thinning out the seedlings to 6ins. apart. Or seeds may be sown in August in shallow pans or boxes filled three parts with fibrous loam, one part leaf-mould, and half-part silver sand; the whole should be sifted finely. The seed should be sown thinly, and covered slightly with fine mould, then placed in a shady frame, and, when the seedlings can be handled, transplanted into boxes 3ins. apart in similar soil, wintered in a cold frame, and planted out in April.

It is almost impossible to describe adequately the exquisite beauty of the Iceland poppy (Papaver nudicaule), with its beautifully crinkled and fluted petals surrounding a charming centre of pollen-laden anthers, and emitting a perfume of the sweetest description, so that wherever offered the blooms always command a good price. The colours range from the purest white to the deepest red, and the intermediate shades are legion; moreover, the beauty is shown to the greatest advantage by the fact that the stems are of a good length—up to 2ft.—and the blossoms poppy-like, droop upon the tall stalks in a very artistic fashion, making the flowers very valuable for cutting purposes.

A trade may also be done in the raising of plants, for these poppies are somewhat difficult to keep from year to year, and are best treated as biennials. It is best, as a rule, to sow in the open where the plants are to remain, and thin them out to the required distance apart, either for sale or for growing on to obtain cut flowers; and the cultivator who shows skill in raising a quantity of plants will reap a good harvest of profit. —R. D.



AN IDEAL PRIMULA FOR THE ALPINE HOUSE, P. WINTERI.

BABIANA STRICTA RUBRO CYANEA.

FEW will dispute the claim I make for this lovely and uncommon plant to be the flower of the flock. I had a letter recently from my good friend Mr. William Mauger of Guernsey in which he said, "I do wish you were here to see my batch of Babiana rubro-cyanea, which as I write is in full blow." I do indeed. If one thing would tempt me into an aeroplane, it would be the endeavour to catch such a sight before the sun went down. The soft medium blue flowers with their bright carmine centres need the kiss of a warm sun before they will open. The little bulbs planted rather thickly—say six to eight in a 5in. pot—make a fine show here in the west Midlands. What must a larger number in the sunnier and more genial climate of Guernsey be like? The sight is a bit of refined gloriousness; or a subdued—yet not subdued—brilliance. I called the plant uncommon in my opening sentence. It is quite correct to do so. How many private gardens have it? In how many bulb lists is it offered for sale? Yet it is quite easy to cultivate. With me it takes pot luck among the freesias. It shares their soil and lives happily among them during the whole cycle of its active life. The only difference that is made between them is that the babiana is given the warmest berth in the houses. It likes this little attention. One more fact in its favour. Half a dozen, well treated, soon increase into a nice little stock.

I may add that the illustration in Nicholson's Dictionary is misleading. I would not know my plant from it.—JOSEPH JACOB.

THE PRONUNCIATION OF BOTANICAL LATIN.

A RECENT paragraph in THE GARDEN discussed the genitive terminations in *i* and *ii*. I understand that an International Botanical Congress has laid down a ruling about them. When the name to be Latinised ends in a consonant, *ii* is added, except when the name ends in *er*, when *i* only is added. When the name ends in a vowel, *i* only is added, except when it ends in *a*, when *e* is added (so forming another genitive termination—the *æ* diphthong).

In the paragraph referred to, an objection was made to the *y* in *Henryus* (As the *y* in the English *Henry* stands for a vowel, I presume the "Latin" genitive will be *Henryi*—as from *Henryus;* not *Henryii*—as from *Henryius*.) but I think it need not trouble us. True, Latin had no *y* on its own native account, but only used it in copying Greek words; but why then may we not use it, if suitable, in copying English words? They are non-native enough (*Henryus* is !). We, at any rate, have put our *y* for the Latin *y* (or the original Greek *u*) in scores of words. Olympus, Odysseus, hyacinth, polyanthus, are instances.

Thinking of these matters, one is led to ask whether something might not be done for the better pronunciation of botanical Latin. Latin botanical names have become a necessary and an everyday part of gardening; some of them, perhaps, are used as often by the gardener as by the professor of botany. As it is, we run the risk of hearing three or four varying pronunciations of the same Latin word. It would be pleasant, if it is practicable, to lessen the danger.

The best—indeed, the only—way is to get the right pronunciation—as right, that is, as the English pronunciation of Latin allows. This means that we must treat botanical "dog-Latin" quite seriously, and very much as though it were real, good Latin. Is it worth while?

I think that it is worth while, because (1) as just said, it is the only means of securing uniformity in pronunciation, and (2) it is nothing like so difficult, even for the ordinary gardener, as people seem to suppose. It is "the ordinary gardener," let me say, whom I have in view, all the time. I believe that many gardeners and lovers of gardens would be only too glad of some clear guidance to the right pronunciation, if they could but get it.

What seems to be wanted is a little pronouncing dictionary of a special kind. It should be quite a small pocket volume, also quite small in price. It might, I imagine, be compiled in some part from existing dictionaries. It should contain the Latin names in alphabetical order. Only names of plants still "in commerce" would, I think, be needed. The length of each Latin syllable—short, long, or "long by position" (the "quantities," as they are called)—should be clearly marked; and there should be a separate mark for "long by position," quite distinct from the mark for the long vowel. (There is at present no such separate mark in use, but there ought to be.) The accent—the principal accent—should be marked for each word. If any eccentric foreign name (*e.g.*, some Polish one) had to go in, a phonetic "pronunciation re-spelling" should be given. And it would be very desirable to give the English meaning of the "real" Latin words (or Greek words in a Latin dress)—*e.g.*, *arenarius*, "pertaining to sand"; *microphylla*, "small-leaved." Finally, the type, the markings for length of syllable and for accent, etc., should be very clear. The user, it should be kept in mind, is possibly more at home with a spade than with a dictionary.

If the gardener looked up any Latin name herein, a glance at the "quantities" and the place of the accent would give him the pronunciation. Even if it came a bit strange for the first week or so, he would soon accustom himself to it. But, further, in front of the pronouncing dictionary, I think there ought to be some two or three pages of "Introductory Explanation." Here, the matter of "long by position" should be clearly explained—not merely stated—say, with an English, as well as a Latin, illustration. The Latin rules for the accent should be given. A few lines might go to these genitives in *i* and *ii*, or in *æ*; and perhaps a word be said about the pronunciation of the final short *e* in neuters like *affine*. And the nominative case of some four Latin adjectives might be cited, so that the different terminations for the masculine, feminine and neuter could be seen.

To the working gardener this may sound quite foreign, more or less difficult, and, therefore, uninviting. But it is not so; at least, it is not difficult. He is not being asked to learn Latin, or anything of the kind, but only to make himself familiar with a simple matter or two connected with the pronunciation of Latin. Let me emphasise this strongly. Any mystery there may be about the things just enumerated is more in their names than in the things themselves. Of such an Introductory Explanation, if its two or three pages were clearly and carefully done, he could get a general mastery in a few hours; allowing for consideration of novel ideas, and so on, let us put it at a dozen hours. To a small but helpful extent, he would then have an idea of the "why and wherefore," instead of taking it all "blindfold" from the dictionary part. The function of the Explanation part is to turn what might otherwise (to him) be senseless, dead enigmas into real, living, understandable things.

Opinions may differ as to the usefulness of the Explanation part, but I think few would deny the desirability, and in fact the positive need, of the Pronouncing part. Messrs. Barr and Sons, in the flower seeds section of their "Seed Guide," give the place of the accent. Anyone turning to the section can see what a help this is, and, incidentally, how important a part the accent plays; and I think the thanks of the gardening world are once more due to Messrs. Barr. But the length of the syllables ought to be given in detail. If this Pronouncing Dictionary were done, any nurseryman, at the trouble of copying them, could give both length and accent in his list, and all should be asked to do so. If the dictionary were also in use at Kew, and other places where gardeners are trained, pronunciation "accidents" might gradually decline.—C. F. GRAY, *Bournville*.

HONESTY.

WHAT we are apt to consider a common flower in the garden in the summer alongside other, admittedly beautiful, blossoms—Honesty—has an added value in dull winter days. The flowers which kept it company in the borders, faded in autumn were uprooted together with the pod-laden plants of this old and simple thing. These were trimmed and the shimmering silvery pods which held the seeds, now in vases before us, are a reminder of the worth of an old-time biennial. Lunaria biennis has its good qualities as a garden flower, but it is of course for its lasting propensities as an "everlasting" that we esteem it most. Somehow, many people, who would be glad of it for winter, forget that it is a biennial, that seed needs to be sown in the early summer for blooming the following year. It is oftener found in the country garden amid old-fashioned things like rosemary and lavender, orange and gold calendulas, Brompton stocks and Canterbury bells, than in more pretentious gardens. —W. LINDERS LEA.

GARDENS OPEN TO THE PUBLIC.

By permission of Lady Loder the Leonardslee Gardens at Horsham will be open on Wednesday, Thursday and Saturday, May 20th, 21st and 23rd from 12 noon to 7 p.m., on behalf of the Sussex Hospitals. Admission 1s. It may be pointed out that these are the only days on which the gardens will be open to the public.

By permission of Dame Alice Godman, D.B.E., the gardens at South Lodge, Lower Beeding, Horsham, will be open on Thursday and Saturday, May 28th and 30th from 11 a.m. to 6.30. p.m. Entrance 1s.

VERMOL

KILLS WORMS AND GROWS GOOD GRASS

Vermol Lawn Sand (Weed Killer)
Vermol Grass Manure (for impoverished turf)
Vermol Insecticide (for Leather-Jackets and other soil pests)
Vermol Grass Seeds (Finest Mixtures for all purposes)
Above specialities also highly recommended.

What users say of Vermol:—

P. D. ELLIS, ESQ., STOCKPORT GOLF CLUB, OFFERTON, Near STOCKPORT, writes—

"I beg to acknowledge receipt of the last parcel of VERMOL. I should just like to add that the past results that we have had from VERMOL have been really excellent and that our continued use of same is a guarantee of the high standard of your product."

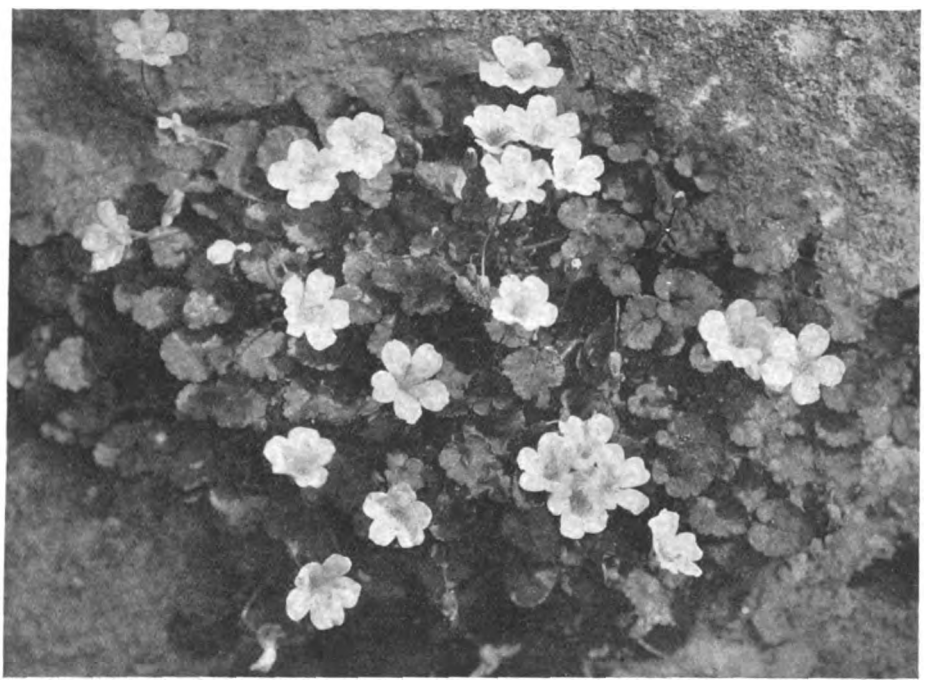
THE POPULARITY OF ROCK PLANTS

THIS ARTICLE DESCRIBES A FEW SUBJECTS WHICH SHOULD BE USED AS THE FOUNDATION OF ALL COLLECTIONS OF ROCK PLANTS.

IT is not my intention, certainly not my desire, here to invoke a flood of correspondence as to what plants should be included in the "best dozen" or "best hundred," for this or that purpose. Also I hope to steer clear of comparisons, which are often not less odious in the garden than elsewhere. But there are a number of plants which stand out pre-eminently among their fellows, plants which have now made their way and hold their positions as established front-rankers, not only on account of their peculiar beauty of form or colour, but also because of their ease of culture and adaptability to any average conditions. They are everybody's plants, the indispensables, yet often enough but feebly represented in gardens whose owners are spending their precious time, energy and money on subjects which, if not less worthy, certainly yield smaller dividends in all that a garden means.

Viola gracilis I would place high up in any list of plants that matter, for its elfish grace is as sweet as its temper. You cannot play with comparisons in the presence of this unrivalled gem, and it so happens that we have growing along with V. gracilis, another first-rate subject, Arenaria montana var grandiflora, which riots in masses of milk-white amid the deep satiny purple of countless white-eyed viola blooms. There is refinement and loveliness as well as bold contrast in that informal array. There is also that realisation of permanence which is an item of hardly less importance in the stock-pot of garden happiness.



ERODIUM CHAMÆDRYOIDES IS ALWAYS A FAVOURITE.

AUBRIETIA IS THE MOST USEFUL PLANT IN THE ROCK GARDEN.

I do not know whether a taste in aubrietias is liable to place one beyond the pale in the eyes of the alpine purist—whether people who value their reputations are ever seen associating with herbs of such plebeian blood. Howbeit, to be candid, I must own up to a profound admiration for many of these abounding crucifers whose names, even of special favourites, I refrain from mentioning, partly because most of them I have forgotten. In alpine phloxes two or three well known kinds claim mention here. P. subulata vars. nivalis and G. F. Wilson (lilacina), will always fill the front seats in the best of company, and then there is a compact, mat-forming variety whose close-set, moss-like foliage is studded with little round flowers in the coolest lilac. This, I believe, is happily titled Fairy. It is a gem of the first water, as incomparable in its own way as the adorable Vivid.

Geranium lancastriense is a rock plant of the very highest merit, yet how seldom does one see its rose-pink, delicately-veined flowers adorning the ledges of the average rock garden. If a trifle florid, G. Prichardii is a comparatively new thing which is rapidly establishing itself among these indispensables, the silver touch of Traversii in its foliage being sufficient to rescue it from that vulgarity which the fierce splendour of its blossoms might inflict. Though I am tempted to add several more geraniums to this list, the mere mention of G. sanguineum alba must suffice.
